## THE CLIMATIC TREATMENT OF PHTHISIS.

BY HAROLD WILLIAMS, M.D.

DURING the past thirty years, a gradual change of opinion has come about amongst medical men in the prognosis of pulmonary phthisis—a change which is due to the advancement of medical knowledge; *first*, with respect to the diagnosis of the disease, and *second*, with respect to its treatment; the former, since by an earlier recognition we are enabled to make an earlier application of our treatment; the latter, because of the improvement in that treatment.

The treatment thus applied, may, for convenience, be divided into the medicinal, general and local; the hygienic and the climatic; and when recovery results, exactly how much is to be ascribed to medicine *per se*; how much to a careful regulation of the hygiene of the patient; or how much is due to climatic treatment, if the climate cure should happen to have been applied, it is impossible to conclude, though in passing I would say, that in my own opinion, a due regulation of the hygiene of the patient is of more value than all other methods of treatment combined, medicine and climate simply being regarded as useful adjuvants to the hygienic treatment.

These brief preliminary remarks, therefore, bring us to the subject of our paper, "The Climatic Treatment of Phthisis," one of the most perplexing questions in the treatment of disease. It has been considered meteorologically, physiologically and illogically, clinically, empirically, and sentimentally. It is governed by no fixed laws; it is elucidated by few published clinical observations, and it is complicated by the utmost conflict of testimony and opinion, as any one may speedily convince himself by a few hours' perusal of the testimony in favor of the different health resorts.

In the mass of literature which the reader will then find before him, he will see that stations, possessing all the extremes of different climates, are alike recommended by their respective advocates; and the conclusion is forced upon the investigator, either that these advocates are prejudiced in their views, or that it must be to some common quality or qualities that all these localities are alike indebted for their vaunted reputations.

I shall not attempt to enumerate these health resorts, for their name is legion; let me simply content myself with saying that I have in my possession a list of one hundred and sixty-eight different island districts and towns, all of which are alike recommended for the treatment of pulmonary phthisis—localities which present every phase of difference in therapeutic climate, and I shall leave it to each one of you to infer the difficulty of deciding the question—"Where shall I send my phthisical patient?" But before we come to an analysis of those different factors which combine together to make up climate, I desire to call your attention to two facts which have hitherto escaped notice in the present context, as directly bearing upon the present question, the idiosyncrasies of certain persons for or against the sea or mountains being disregarded for the present.

The first of these facts is, that with or without treatment, certain cases of phthisis naturally tend to recovery, in proof of which I cite the cicatrized lungs of persons dying from other diseases as found in the autopsy

room; also those cases familiar to each one of us in practice, of recovery from those physical signs which we are accustomed to associate with phthisis—of recovery, too, which often occurs under the most unfavorable circumstances. I, myself, can recall the case of a man with well-marked signs at the apex of one lung following upon copious hæmoptysis, who was completely restored to health while living in one of the most crowded and unhealthy localities in this city, and I am sure I need not remind you of the two cases reported by Dr. E. G. Cutler<sup>1</sup> in a recent number of the *Boston Medical and Surgical Journal*.

This rule, that certain cases of phthisis tend to recovery, I think may be regarded as an axiom; and the same holds good of its converse, that certain cases of phthisis tend to progressive advancement in spite of all that treatment can accomplish to the contrary. To express this more plainly, I may say that some cases will inevitably recover, while others will as inevitably die, notwithstanding the treatment which may be applied to them, so that recovery or death in any given case should not be ascribed to climate alone, in disregard of other factors.

The second consideration which I would urge upon you, is the importance *per se* of any change of climate; a change which is often accompanied by a change of scene, of habits, of exercise, of food, of dress, of thought, of companionship and of surroundings; such changes are generally pleasurable changes, and "states of pleasure are concomitant with an increase of some or all the vital functions." In my opinion, much of the gain which is derived from a change of climate, is due not so much to the curative properties of that climate as may be attributed to the effect of the change.

But in spite of these facts, that some cases tend to recovery while others as necessarily tend to decline, and that the mere change of residence is valuable in itself, yet this does not preclude the possibility that a given change of residence may be better than another; that some classes of health resorts may be more efficacious than others, and for other reasons in addition to that change; and it therefore becomes our duty to examine the evidence which is adduced in support of these different groups of health resorts.

In a general way, these health resorts may be divided into four principal divisions; the sea itself, island and sea-board stations, inland stations, and mountain stations; and it may be said that the sea air, by which I mean the air of the sea as experienced upon shipboard, and mountain air as experienced at an elevation of 6,000 feet, represent the extremes of therapeutic climate. Between these extremes, the inland stations like Aiken and the Adirondack region; and the island and sea-board stations, like the Bermudas and St. Augustine, lie, each possessing in a degree, the peculiarities of the extreme to which it is most closely allied.

Besides the common attributes of sunshine, winds, rains, etc., varying with the different local circumstances of each place, the meteorological peculiarities of these extremes may be summarized as follows:

Sea-air differs from the other groups in that it contains:—

*First.* The maximum amount of oxygen and the highest degree of atmospheric pressure.

*Second.* It contains the maximum amount of aqueous vapor.

*Third.* It contains the maximum amount of ozone.

<sup>1</sup> Boston Medical and Surgical Journal, March 26, 1885, p. 295.

*Fourth.* It contains the minimum of organic impurities.

*Fifth.* It contains small quantities of saline particles, iodine and bromine.

*Sixth.* It presents more regular variations of barometric pressure.

*Seventh.* It presents the minimum diurnal variations of temperature.

Mountain air, on the contrary, contains :—

*First.* The minimum amount of oxygen and the lowest degree of atmospheric pressure, both diminishing in direct ratio to the height above the sea.

*Second.* It contains the minimum amount of aqueous vapor.

*Third.* It contains an excess of ozone.

*Fourth.* It contains a diminished amount of organic impurities.

*Fifth.* It presents great and irregular variations of barometric pressure.

*Sixth.* It presents the maximum diurnal variations of temperature.

*Seventh.* It is lower in temperature.

*Eighth.* It is characterized by greater "diathermancy" of the air, since by diminished density and humidity, it offers less obstruction to the passage of the sun's rays.

Some of these distinctions are, of course variable, though nearly enough exact for purposes of comparison, the only inaccuracy being in the local surroundings of the individual stations. For example, if we have a mountain resort in a valley, like Davos Platz, crowded by consumptives and badly drained, the air of that resort would probably contain much of those organic impurities most to be dreaded. Furthermore, the position of a locality with respect to neighboring heights, soil, direction and character of winds, latitude, and neighboring bodies of water, must, in a measure, modify some of these general rules.

Now these meteorological differences, although at first sight appearing of radical physiological importance, are in truth of little value in the treatment of phthisis, so far at least, as is demonstrated by our present knowledge. On the contrary it is probably due to qualities common to all groups that all are indebted for their reputations, as a brief review of these considerations will show us.

*First,* as regards the increased quantity of oxygen at the sea level and the converse diminution at altitudes, it has been shown by Dr. Parkes that so long as the oxygen does not sink below fourteen per cent, as much is absorbed as when it is in its natural proportion,<sup>2</sup> a fact which would vitiate alike all theories based upon an increase or decrease of the oxygen in the atmosphere, since in none of the climates recommended for the treatment of phthisis does the oxygen sink below fourteen per cent. With regard to the consideration of the difference of barometric pressure, however, more attention must be paid, though like the variation in the quantity of oxygen, it seems to me of little practical importance. That an immediate change from a low to a high level is often a dangerous experiment for a person suffering from phthisis no one can deny, although I believe that the effects of such changes with respect to therapeutic heights have been greatly exaggerated. But be this as it may, the effects of sudden and extreme changes are not our present consideration. We are speaking now not of sudden de-

leterious changes, but of permanent favorable changes, slowly accomplished.

As none of the advocates of low levels urge the consideration of increased pressure, I shall confine my attention solely to the effects of diminished pressure, since it is largely upon this meteorological consideration that the advocates of high altitudes base their claims.

The nearest approach to a theory, that I have been able to find, as to the effect of diminished pressure upon phthisical patients, is that advanced by Dr. Denison, which I quote as follows:—

"With the atmosphere, let us say, one-fifth rarified, respiration is deeper and more frequent. Here the density of the air in the lungs during inspiration would seem to be lessened in proportion to the greater quantity of air which has to be breathed. This increased approach to a state of vacuum in the lungs tends to draw the blood quickly into the pulmonary vessels which movement of the circulating fluid is aided by the accompanying increased action of the heart."<sup>3</sup> This increased capillary circulation in the lungs acts, Denison claims, in two distinct ways: first, by being in "opposition to stasis of blood which is an early stage of inflammation," and second, that by the pressure these expanded vessels exert upon the intercellular tissue, they crowd outwards the products of inflammation.

Now this theory seems to me untenable both in its data and its conclusions. In the first place it assumes that respirations are increased in force and frequency at therapeutic altitudes, whereas upon this point there is conflict of testimony, Jourdanet<sup>4</sup> asserting that respirations are lessened, while Coindet maintains that they are increased, thus showing that the question of increased respiration has still to be settled. But even supposing the respirations are increased both in force and frequency, such increase would seem, not to *lessen* the density of the air breathed, thus causing a vacuum in the lungs, but, on the contrary, it would seem rather to *increase* the density of the contained air. For the greater the quantity of air in the lungs, the greater would be the distension of the elastic chest walls, and consequently the greater the pressure exerted upon the air contained, thus increasing its density. So that if we admit that the respirations are increased this increase should be regarded as the probable factor by which the organism accommodates itself to diminished atmospheric pressure rather than as a means of causing a vacuum, as Dr. Denison claims in support of his theory. Moreover, Dr. Denison claims that this increased pulmonary circulation is also supplemented by increased action of the heart, whereas Jaccoud says that the acceleration of the cardiac pulsation is only temporary and ceases at the end of a few days.<sup>5</sup> But for purposes of argument, admitting that the air in the lungs *does* approach a state of vacuum, Dr. Denison has yet to show the advantage of this state, even provided that it did increase capillary circulation. For to say that "stasis of blood is an early stage of inflammation," is but a partial statement of the case, while to claim that the pressure of the dilated vessels upon the intercellular tissue crowds out the products of inflammation is purely conjectural, and a simple statement of what he desires to prove. Without stronger evidence than that afforded by this theory alone in favor of diminished

<sup>1</sup> Parkes' Practical Hygiene, 1881. Sixth ed., p. 129.

pressure, therefore, it seems to me that we are not justified in sending our patients to the mountains.

Or again, in speaking of the doctrine of immunity from phthisis, which I shall allude to later on. Dr. J. Schrabner in his address before the Vienna Meteorological Society, translated by Dr. Geddings of Aiken, says:—"that the altitude at which this immunity commenced, varied with the latitude, being higher the nearer we approach the equator," a fact which would seem to demolish the theory of diminished pressure alone, as an agent of value in the treatment of phthisis. Moreover, when we consider that artificially increased pressure is a method of treatment at present in vogue (Waldenburg's method), as well as is diminished pressure (high altitudes), it seems to me that we must admit that the effects of pressure upon phthisical patients are by no means clearly understood.

With regard to the effects of a difference in quantity of the aqueous vapor in the atmosphere, the advocates of high altitudes have much to say, while the advocates of the sea say little. Of the former, all assert their belief in the importance of dryness of the air although none have given sufficient reasons for upholding that belief.

Here it must be understood that we are dealing with the question: "Does an extreme dryness of the air exert a more favorable curative influence upon the phthisical than does extreme moisture?" and not with that greater question of the development of phthisis because of soil-moisture. We must remember, that, notwithstanding how great the effect may be that soil-moisture exerts upon the development of phthisis,—an effect which is probably due to the fact that the exhalations of damp ground are inconsistent with hygienic perfection, and to its affording a suitable soil for the development of germs,—that the question now before us, is of the effects of dryness or humidity of the air upon the disease, already established, upon which subject the physiological evidence is again vague and conflicting.

For example, the statement, "The watery vapor abstracting an undue amount of heat from the respiratory track and giving rise to catarrhs, coughs, or perhaps inflammation" is met by the assertion, "Freedom from colds because of humidity."<sup>6</sup> Or again the statement, "the natural consequence of this dryness (of the air) is the abstraction of so much water from the respiratory tube that the lungs are *proportionately colder*, the consequence of which may be that some antipyretic effect is produced" is met by the experiments of Beneke who has shown that heat is lost more readily at the north sea than at high altitudes<sup>7</sup> all of which go to show the unsettled state of the medical mind upon the effects of humidity. How the importance of aqueous vapor as a factor in the cure of phthisis should have gained ground I do not know. I can simply say that I know of no evidence proving that importance.

*Fourth.* With respect to ozone and "its effect upon man, little is known."<sup>8</sup> A fact of considerable importance, when we reflect that patients are daily sent to the Adirondacks, to Aiken, and to the New Jersey and Georgia pines because of the increase of ozone which is said to follow in consequence of the turpentine

exhaled from the trees.<sup>11</sup> In this context I would say that those who rely upon this theory repose their faith upon broken reeds, since, not only is it claimed by Brown "that ozone is nearly or quite inoperative" in the curability of disease, but also since it is known that turpentine has the peculiar property of preventing the further formation of ozone.<sup>12</sup> In regard to this question of atmospheric electricity a curious claim has been advanced by Denison, who says:<sup>13</sup>—"You lie down to sleep on the ground as only a tired camper can, and rise in the morning from your *negative electric* bed, to stretch yourself in the *positive electric* air." As the "positive electric air" is caressing the "tired camper" quite as much while he is sleeping as when he is stretching (unless he should have covered up his head with his blanket), I conclude that it is the stretching which Dr. Denison intends to inform us is of use, though why an invalid need go to Colorado, in order to stretch himself in the open air is not so evident.

*Fifth.* Sea-air contains a small quantity of saline particles of iodine and bromide, which, says Yeo,<sup>15</sup> "may not be without real influence on some organisms."

*Sixth.* Mountain air presents less regular variations of barometric pressure, and an increased diathermaney. Upon these points of difference nothing is proved: of the former, it is claimed, that variations of barometric pressure exert considerable influence on the circulation of the air contained in the soil—the so-called ground-air—an air which is likely to be contaminated with carbonic acid, marsh gas and occasionally sulphuretted hydrogen;<sup>16</sup> and of the latter, it is claimed by Denison<sup>17</sup> that since mines are unhealthy because of the absence of sunshine, and since the power of the sunshine increases with increasing altitude, therefore "the beneficial effects of sunshine increase with increasing altitudes." Denison's syllogism disregards latitude, and if true, would go to show that Colorado was less suited for consumptives than all points between it and the equator if of equal altitude, since the altitude being the same the effects of the sun's rays must be increased as we approach the equator, as is shown by the increasing altitude of the snow-line.

*Seventh.* The sea air presents the minimum of diurnal variation of temperature; a factor which seems to me greatly in favor of the sea, inasmuch as the important effect upon health of sudden and great changes of temperature by promoting or checking perspiration is generally admitted. Moreover, it must be borne in mind, that these changes, however great they may appear with us, are still greater in many of the mountain stations and less upon the sea itself. The annual range at Fort Sully, for example, is 150° F.,<sup>18</sup> whereas in the Eastern or Atlantic States it is 106°. Again, the range at Denver for the month of March, 1880, was 83°, whereas in Santa Barbara, the maximum variation for the month of January, 1879, was 29° F.,<sup>19</sup> while again, according to the report of the Challenger, the diurnal range of the temperature of the air over the North Atlantic on a mean of 126 days was 3° 21',<sup>20</sup> figures which are taken from the data at hand, simply

to show the variations of temperature. And in this context I would say that such tables of temperature as are usually given are of little practical value in the selection of a health resort. It is the *diurnal range* that we wish to know, and in such reports the diurnal range is carefully avoided.

*Eighth.* Mountain air is lower in temperature, a factor which again seems to me in favor of the sea, since the coldness of the mountains is opposed to the principles of hygiene in so far as it admits of less open air exercise and prevents a suitable ventilation of the houses; the evil effects of which latter are augmented by the herding together of consumptive patients in hot, ill-ventilated rooms during the major portion of the twenty-four hours. I know of no better illustration of this than is afforded by Hassall, who writes: "Few invalids, who go to Davoz . . . spend more than four or five hours in the open air. . . . In his rooms, he breathes the rarified air, heated by stoves, rendered impure by the number of persons congregated together in a small space, all breathing the same air."<sup>22</sup>

*Ninth.* Both sea, and to a slightly less degree, mountain air, contain the minimum amount of organic impurity; the sea, because there exists no source of origin, the mountains, because of the paucity of population; the lowness of temperature, the presence of snow and the prevalence of winds.

Thus, then, to sum up the meteorological differences between the air of the mountains and the air of the sea, it would seem that the sea air possesses certain possible advantages over that of the mountains in that it is warmer and purer, and that it presents slighter variations both of temperature and humidity.<sup>23</sup> But this it must be remembered, is the air over the sea itself, air that can only be prescribed through the medium of ocean voyages, a prescription open to the grave objections of idiosyncrasy against the sea; sea-sickness; anxiety at leaving friends, fears of dangers, lack of companionship, variety and exercise; and above all, inferiority of food. Added to which is the difficulty of selecting a voyage which shall extend over a sufficiently long period of time. Thus, though it would appear that the sea-air is theoretically somewhat better than other climates for such consumptives as can avail themselves of it, we cannot but recognize, in view of these ulterior considerations, that it is available but for few.

Island and sea-board stations resemble most nearly the sea; differing from it both with respect to variations of temperature and humidity, and purity of the air; the latter being probably dependent upon the density of population, the age of settlement, the character of the soil, and the prevalence and direction of winds. Inland stations, on the other hand, resemble the mountains or the sea according to their altitudes and consequent humidity and diurnal and annual ranges.

Physiologically speaking, therefore, it may be said that mountain air is no better than island or sea-board air because it is colder and more liable to sudden and excessive changes of temperature, while, on the other hand, it may be contended that island or sea-board air is no better than mountain air because of its diminished purity; the factors of difference in each class thus becoming, in a comparison, factors of equalization. And in this context I would allude to the idiosyncracies of individual patients for or against the sea or mountains,

I think there can be no doubt that some people feel better at the sea than at the mountains, or *vice versa*, in the same way that they manifest a different tolerance of drugs, and I believe that these individual preferences should be consulted in the successful treatment of phthisis by climate, although no definite rule can be laid down with this respect unless it should be that in general people above the middle age do better at the sea.<sup>24</sup>

Clinically considered I again find the evidence vague and incomplete. I am aware of but three statistical reports of any value in favor of the high altitude treatment; those of Spengler,<sup>25</sup> concerning cases at Davoz Platz, 5100 feet above the sea; those of Denison,<sup>26</sup> of cases occurring in Colorado, Wyoming, and New Mexico, and those of Ch. K. Williams,<sup>27</sup> also of cases at Davoz. Of the island, seaboard, and inland resorts I can find no statistical report whatever of completeness. From the reports of mountain treatment no conclusion can be drawn.

In Spengler's statistics of 323 cases, 73 recovered or about one-fourth, as compared with the one-sixth of recoveries cited by Loomis<sup>28</sup> as the result of mixed treatment. Yet we are informed by Ch. K. Williams that among the patients at Davoz "there is a limited amount of disease (and that too in an incipient form)."<sup>29</sup> From this it would appear that a large number of Spengler's cases were of incipient phthisis, or selected cases, and from such material it is evident that no conclusion can fairly be deduced. 190 of the 323 are claimed to have been improved, but temporary improvement belongs to the natural history of phthisis, as is well known to every practitioner of medicine. Above all, Spengler's observations were made during one and a half years, a period of time far too short to enable us to arrive at valid conclusions. Denison's statistics consist of 260 records, 58 of which are excluded, 34 for reasons which seem to me insufficient. Of the 202 remaining cases, the observations extended only over an average period of one and three-fourth years, thus representing "an analysis of 50 years, spent by 202 consumptives in Colorado," as Denison more attractively puts it. But actual results are not given. Dr. Denison merely speaks of improvement, and temporary improvement, as I have said, belongs to the natural history of the disease. Moreover, improvement is often exaggerated especially when recorded by so enthusiastic a partisan as Dr. Denison. Williams' statistics present similar objections. The illogical argument in favor of certain localities may be briefly stated as follows: In the locality A phthisis is unknown, therefore the locality A offers the greatest hope of recovery for persons suffering from phthisis. Such an argument is of course absurd, especially in view of the present light thrown upon the cause of the disease by Koch in his renowned discovery. We do not argue that because typhoid fever is unknown in a certain town, that town is especially adapted for the treatment of cases of typhoid, and should we so argue I think it would be safe to infer that this town would not enjoy its reputation for any considerable period of time. Moreover, to say that it is because of the climate alone, that the inhabitants of a certain Swiss

<sup>22</sup> Hassall, *Lond. Lancet*, 1879, II, p. 132.

<sup>24</sup> Loomis, *op. cit.*, p. 205.

<sup>25</sup> Peters, *Edinb. Med. J.*, 1880-81, XLVI, p. 1100.

<sup>26</sup> Denison, *op. cit.*

<sup>27</sup> *Lond. Lancet*, 1879, II, 191-233.

<sup>28</sup> Loomis, *op. cit.*, p. 197.

<sup>29</sup> Williams, *Lond. Lancet*, *op. cit.*

hamlet enjoy their immunity from phthisis, is illogical in the extreme. Who can say that such immunity is not due to the rugged habits of the mountaineers? to their hygienic active open-air lives? Or how are we to reconcile such a doctrine with the statement of Parkes<sup>30</sup> that in the Swiss Alps while phthisis is rare among the men who live in the open air, yet it is very prevalent among the women, who, "employed in making embroidery, congregate all day in small, ill-ventilated low rooms?" I, for my part, have no more doubt that it is the open-air life and not the climate, that has granted this immunity to the men than I have that it is the sedentary occupation and impure air *and not the climate* which has proved so destructive to the women. Moreover, upon this subject of immunity the greatest contradiction of statement prevails. For example, the statement, "the exceeding fatality of consumption, etc."<sup>31</sup> in Florida, is answered by the counter assertion that Florida at the time of writing had no "State Board of Health and no registration of deaths outside of the city of Jacksonville,"<sup>32</sup> showing that any statement in regard to the prevalence of consumption in Florida, at that time, must have been purely conjectural; and again, "The investigations of Hirsch have shown that neither the geographical position nor the temperature have anything to do with the prevalence of consumption . . . which is very common . . . in Siberia,"<sup>33</sup> while on the fifty-ninth page of Denison's book we find on the contrary the assertion: "In Siberia phthisis is very rare."<sup>34</sup>

Another form of the illogical argument at present in vogue is: That A. recovered in —ton, therefore we should send B. to —ton. Yet this argument might be as correctly stated by saying: "C. died in —ton, therefore we should *not* send B. to —ton.

The sentimental aspect of the question demands but little notice at our hands. It is hardly necessary for me to call attention of members of this Society to the physiological effects of the perfumed zephyrs, or the health-giving breezes which figure so largely in the descriptions of health resorts found in our medical journals. I have simply alluded to the subject in order to remind you that sentiment is not science and consequently should be shunned while dealing with questions of scientific importance.

Thus, then, to sum up, it seems to me we must admit that at the present state of our knowledge the meteorological differences of climate have been proved to be of little importance in the treatment of phthisis; and furthermore, it seems to me that clinical evidence would support this conclusion; for the burden of proof lies with those advocates who plead in favor of special climates, and such proof, it seems to me, is yet to be forthcoming.

But the beneficial effects of a change of climate in the treatment of phthisis is a matter of common belief if not of statistical proof, and such beneficial effects I believe to be due to factors common to all groups of health resorts, varying only in degree. These factors are: The change itself; the purity of the air;<sup>35</sup> the increased number of hours of open air exercise permitted;<sup>36</sup> and the improved hygienic surroundings of the patient; and this belief I shall hold until better

evidence is adduced in favor of any of the four groups of health resorts. But before closing, I would say that if these three groups of health stations (sea voyages, the best being now disregarded) are admitted to be similar, yet individually these places are not to be regarded as equal; the superiority which one exercises over another being that it affords greater hygienic advantages.

An ideal health resort for this disease should be sparsely and newly settled.<sup>37</sup> It should possess a pure water-supply and adequate drainage. It should be of a dry and porous soil and should be favorably situated with respect to neighboring heights and marshes and prevailing winds. It should be equable in temperature, and should possess the maximum of pleasant weather. It should not be so hot as to be enervating, nor so cold as to prevent out-door exercise and proper ventilation of the houses. It should afford plenty of amusement; it should not be crowded with consumptives, and it should be sufficiently unfashionable as to admit of hygienic dress.

Above all, it should afford suitable accommodations for the invalid. The house should be carefully situated and thoroughly ventilated; the food should be abundant, palatable, and varied; and the sleeping-room should be large and sunny, and afford sufficient ventilation, and I believe that such a health resort as affords these advantages in the highest degree will be found by experience to be the best locality for a phthisical patient, be the barometric pressure, the aqueous vapor, and "the diathermancy" what they may.

In conclusion, I would say that the views arrived at in the present paper are by no means new, although they have not to my knowledge been similarly stated. For example, Parkes, in his *Practical Hygiene* has said: "The best climates for phthisis are those which permit the greatest number of hours to be passed out of the house,"<sup>38</sup> and again, Sir Joseph Fayrer, President of the London Medical Society, expressed a similar opinion when he said that: "too much importance had been attached to altitude; it was pure air that is of most value."<sup>39</sup> For myself, I believe that more attention has been paid to the meteorological differences of climate than their efficacy has been shown to deserve and that too, to the great detriment of such patients as are unable to avail themselves of them, since, as they cannot be sent to such places as their physicians regard most valuable, they are not sent away at all. To such persons I believe that a consideration of what I have said, must prove of real value. Some changes of climate is possible for all — even the artisan or the laborer can pursue his calling in the country as well as in the city, or upon the sea-board as well as in the interior.

— Dr. A. Seibert recently reported before the New York society of German physicians, the case of a baby, four months old, which he had treated for gastritis, and which for eighteen consecutive days almost uninterruptedly had a temperature of over 106°. The child recovered.

## WHAT BECOMES OF INTRA-PERITONEAL LIGATURES.

BY J. C. IRISH, M.D., OF LOWELL, MASS.

SINCE the intra-peritoneal treatment of ovarian pedicles with short ligatures has so universally replaced the older modes by clamp or ligatures brought out at the lower angle of the wound, it has become a question of great interest to learn what becomes of these foreign bodies enclosed in the abdominal cavity. This subject has been extensively investigated by Spiegelberg and Waldeyer, with a series of experiments upon animals. Doran, also, reports ten cases in which he has examined the pedicle at some time after an ovariectomy.

These observers found that a plastic effusion extending from the proximal side of the pedicle to the distal, over the ligature, would establish a vascular connection with the ligatured portion, sufficient to prevent its necrosis. Afterwards, young granulation cells would spring up and insinuate themselves among the individual fibres of the ligatures, separating the threads and unravelling them, and finally, that these fibres would become entirely absorbed.

In exceptional instances, however, the ligatures would slip off the stump, become encysted, and remain without further change.

I have been unable to learn the length of time required for the completion of this process of absorption, or the variations in extent of time that occurred in different cases. The following case, however, demonstrates that complete absorption of the ligatures may take place, as it seems to me, in a very short space of time.

January 13, 1885, I removed an ovarian tumor from a patient at Lowell. The pedicle was ligated in two sections with "Tait's Knot." The ligatures were cut short and enclosed in the abdominal cavity. The patient made a rapid and complete recovery from the ovariectomy. But May 5th, that is four months less eight days after the date of the ovarian operation, she died of acute pulmonary tuberculosis. At the post-mortem examination, a very careful search was made for the ligatures. All trace of them had disappeared from the pedicle. Although it was very improbable, from the manner in which the pedicle had been tied, that they could have slipped off and become encysted, still so thorough an examination of the pelvic cavity was made as to convince us that it was impossible that they had found any place of lodgment there. Therefore, in this instance, the entire absorption of the ligatures had taken place in twelve weeks or less.

## DYSENTERY.

BY THOMAS BUCKLER, M.D., BALTIMORE.

It is not our object to discuss, at this time, the etiology of dysentery, nor to show how the passing of blood and mucus is produced, in hot climates, by the eating of unripe and stale fruits or indigestible food of any kind, but more especially those articles which, not being readily digested, are likely to undergo septic changes, as is the case with food so simple as badly-boiled, half-brown rice. Neither is it our purpose to explain the pathology of colitis, or to show how crude, partially digested matters, passing to the large intestine, set up irritation, erythema, and inflammation of the crypts and follicles in which the morbid action unrelieved, erosion and ulceration commence, on the

eight day. It is presumed that the practitioner understands all these matters of fact, and that catarrh of the colon is also induced, by exposure to inclement weather, and that dysenteric colitis from all these causes, is invariably characterized by the symptoms tormina and tenesmus.

In all parts of the world, there is no disease so badly, irrationally, and unphilosophically treated, as dysentery, hence the fatality, not only of this malady, but also, from abscess of the liver, one of its most common and fatal sequences.

Pus, taken up at the ulcerated ends of the portal veins, is carried directly to the acini and interstitial cellular tissues of the liver, where it reproduces its kind, and a single, or multiple abscesses, of greater or less size result.

The engorged follicular bodies, or glands, imbedded profusely, in the free mucous membrane, pour out, at first, mucus alone, which soon becomes mingled with blood, and after ulceration has taken place, on the eighth day, with pus also.

## SALINE TREATMENT.

The principle of this treatment consists in the use of wet, saline purgatives, whereby the *idiopathic dysentery is converted into a symptomatic diarrhœa*. The saline, acting on the exhalents, unloads the engorged glands, mucus ceases to be secreted, and a profuse watery discharge takes its place. To accomplish this, half an ounce of Rochelle salts—tart. potass—and sodium, or a like quantity of Epsom salt, (sulphate of magnesia) or glauher salts, sulphate of sodium, is sufficient. As soon as the action of the salt is over, give twenty drops Sydenham's tincture of opium, eight of black drops, or a grain of powdered opium. This usually closes the case, or to use the popular phrase, cures (I hate the word cure) it. If, after the effect of the anodyne passes off, tormina, tenesmus and the voiding of mucus from the bowels, are renewed, then, the remedies, as directed above, are to be repeated, and in forty-nine cases out of fifty nothing more is required to be done. Early in the Mexican war with the United States, Dr. S. Tilghman, having obtained the place of assistant surgeon in the army, went directly from the Baltimore Alms House to Vera Cruz, where the troops were dying, at the time, of dysentery, like sheep, of the rot-charbon. Introducing the saline treatment, the patients all recovered, and, three weeks after landing, Dr. Tilghman was appointed chief medical director of the place. Dr. Tilghman wrote me that all he did, was to adopt the saline treatment used at the Alms-house.

## POWDERED NUX VOMICA.

But where the vaso-motor nerves are paralyzed, by blood poison, the mucous and sanguineous discharges, instead of stopping under salines, go on more profusely than before their use; and in rare cases, the tormina, tenesmus, and discharges become more active; the pulse gets small, frequent, and sometimes thready; the extremities become cool, as does also the sweaty surface of the trunk; the patient, often, in a squeaky voice, complains of great weakness, and, if the stools are examined, they will be found to be nothing less than the product of a "bloody flux," all, or nearly all, the mucus having disappeared from them.

In this emergency, a grain of pulv. nuxis vomica, may be given to a child, and five grains for an adult,

with the best results, and the attendant will be astonished, as I have been, at the salutary effect of this agent, often changing, as it does, the entire complexion of the case. I have never ventured to give more than five grains, on two consecutive days. Strychnine, in this condition, does no good, being taken up from the stomach, into the circulation; but given in the form of the powdered nut, the remedy gets down into the intestines, and the strychnine being slowly dissolved out, is used at the place where it is wanted.

#### CAPSICUM FOR PARESIS OF THE HEPATIC NERVES.

I have seen one endemic and one isolated case, besides, where the patients were suddenly seized with slight chilliness, followed by tormina, tenesmus and great weariness. The pulse small, feeble and frequent; the skin cool, covered with an oily sort of sweat, and the stools, altogether the most characteristic sign of this peculiar form of dysentery, were mucus, having the exact color of hickory ashes. In this formidable condition, nothing is required, but to give five grains of capsicum, every three hours. By the time, or before six of these pills had been taken, a profuse flow of bile came away, changing entirely, not only the character of the stools, from gray mucus to bile, but improved the condition of the patient so much, that return of strength, and convalescence, were at once established.

In this epidemic which occurred at Baltimore, in 1848, for the most part, south of Pratt and west of Light Streets, on the alluvial formation, many cases, treated with small doses of *o. ricini*, calomel and opium, ipecacuanha, and by other means, were detained in bed for a long time, and a number of them were fatal, whereas the cases, relieved by capsicum alone, were never kept at home longer than three or four days at most.

I presume that capsicum, in this condition, acts as a fillip to the hepatic ganglia, thereby enabling the secretory apparatus of the liver to resume its work.

#### FALSE DYSENTERY: PROPERLY HEMORRHAGIC PURPURA.

There is still another form of disease commonly regarded as dysentery and treated for it, because the patients have sanguinolent stools, containing the coloring matter of blood, but without a trace of mucus. Of these I remember to have seen five cases, all of which were from malarial regions. The first, having some spots of purpura hemorrhagica, on different parts of his body, gave me the key to the treatment of it, and in all the others, in which there was no sign of petechiae or of subcutaneous extravasated blood to be found, except in two, there was icteric coloring of the skin and whites of the eyes. They all recovered rapidly under ten grains of bicarbonate of potassium, given every four hours, with the juice of limes or lemons, while effervescing, and potato paste, for food. In other words they took the usual remedies for purpura hemorrhagica, and the allied disease, scurvy. If the jaundice, in these cases is deep they might also take, with advantage, at bedtime, fifteen grains of benzoate of sodium, with ten grains of the extract of taraxacum.

There may yet be other forms of dysentery with which my acquaintance has not been made. I have merely spoken of things as they came under my observation.

For dysentery, solids are, as a rule better than

liquids—properly cooked cold rice, boiled fish and tender beef, mutton or chicken, roasted, rather than ice water, beef tea, chicken and mutton broth, or milk.

Cases, malarial in their origin, should be removed and kept supplied with pure fresh air. The treatment of dysenteric ulceration of the colon has already been considered in a paper on the typhoid malady.

#### REPORT ON THERAPEUTICS.

BY FRANCIS H. WILLIAMS, M.D.

IX connection with a report on therapeutics, it is interesting to notice some of the broader views which are, from time to time, suggested in this branch of medicine, rather than limit our attention to the observations and reports which are so abundantly made on single remedies by good, bad, and indifferent observers. Such a paper as that of Dr. J. Mitchell Bruce<sup>1</sup> on "Natural Recovery from a Therapeutic Point of View," will be of interest to many physicians, though but scant justice can be done it here. He says, "when we attempt to formulate our conception of treatment and cure in the light of our present knowledge of pathology and pharmacology, we find that we are compelled to acknowledge a power of natural recovery inherent in the body. This has been acknowledged by many writers in all ages."

The author attempts to demonstrate his reasons for believing "that a natural power of prevention and repair of disorder and disease has as real and as active an existence within us, as have the ordinary functions of the organs themselves; that general therapeutics is therefore as firmly founded as physiology; and that the scepticism of treatment, which is so rife in these days of active pathological research, is thoroughly unsound."

He proposes to inquire what methods nature adopts; how it has come to pass that nature possesses such a power of preventing and treating disease; and how nature's efforts are limited when they demand assistance, and how a knowledge of her methods can be applied in the art of healing.

To learn how the various methods of remedy which nature adopts, a case of obstruction at the aortic orifice with compensating hypertrophy of the left ventricle, is cited as an excellent instance of natural cure. The cause of disease is overcome by or rendered inoperative by a natural provision—the display of greater energy; and the method founded on it is, indeed, constantly practiced in the case of voluntary muscles, and is known as exercise. In other systems than the muscular, this method, in the opinion of the author, is not sufficiently appreciated, and neglect of the exercise of organs and functions, appears to him to be one of the most unfortunate features of the therapeutics of to-day. Rather than bolster up a weak digestion with pepsin, ingluvin and papain, or by using predigested foods, he prefers an entirely opposite course as being more scientific and more successful, such as the use of alkaline stomachics (acting as an artificial saliva, stimulating the acid gastric juice) before food, in combination with stimulants of the palatal and gastric nerves, such as aromatic bitters, wholesome wines, thoroughly appetizing food, a properly arranged menu, and cheerfulness of company and of the general surroundings at meal times.

He also objects to the habitual use of saline bitter waters as laxatives, as they simply relieve the muscular

<sup>1</sup> Practitioner, April, 1885.

activity of the bowel of its proper work, and render the bowel more languid than before. Senna, castor oil, aloes, cascara and rhamnus frangula, as well as many tonic measures directly or indirectly applied to the bowels, are the proper remedies.

"If we go to another system—how common it is for us to meet with cases of nervous disorder, such as epilepsy, where the patient has been allowed to sink into an almost vegetable existence, through the utter neglect of bodily and mental exercise. Dosed with bromides, over-fed, coddled, with constipated bowels, disordered liver, thick urine, his muscles will hardly carry the patient up stairs, his mind is a blank. Look at the same man a month after proper exercise of mind, muscles, and viscera has been enforced." Other conditions where the same general methods may be employed with advantage, are also outlined.

As regards other spontaneous remedies of nature, vomiting is a conspicuous example, the diarrhoea of indigestion is another instance of the same, as are also coughing and sneezing. All these observations suggest that disease may be prevented or removed by the direct removal of its cause. The success of the surgeon with antiseptics is an instance of how much may be done by following this method, and the physician probably does not take sufficient advantage of the principle. Emetics seem to have less reputation than they deserve, and he condemns the insufficient use made of saline expectorants to increase the secretions in certain forms of bronchitis and asthma, especially if their action is neutralized by opiates which check the flow of mucus and depress the whole respiratory mechanism.

Dr. Bruce does not advocate in all cases a vigorous and active method of treatment. He is also a believer in the method of *rest*, which he also calls the method of *avoiding the cause*. Rest, he says, is in apparent conflict with the method of exercise; and the discrimination of the proper time and place for either measure, is one of the most severe tests of therapeutical skill.

The interesting discussion of the treatment of chronic Bright's disease, and some of the methods of treatment by removing the effects of disease, cannot be readily given here in outline. In the second part of his paper, the author proceeds to inquire how it is that nature has come to possess the power of preventing or removing disorder and disease.

#### HYOSCINE.

In the January number of the *Therapeutic Gazette*, Prof. Wood writes of the physiological and therapeutical action of hyoscyne. The variety of the opinions held by various practitioners makes this communication the more interesting. The salt employed was Merck's crystallized hydrobromate, or in a few trials, the hydroiodate of hyoscyne. "Experiments on animals, which are given in the original article, show that hyoscyne acts upon mammals chiefly as a spinal depressant; that it is a centre-respiratory depressant, causing death by asphyxia; that it has very little effect upon the circulation, what influence it exerts being in the normal animal set aside by the asphyxia it produces; that it does not paralyze the pneumogastries; that in enormous doses, it paralyzes the vaso-motor system; that on the heart itself, its influence is feebly depressant." The drug was also taken by Dr. Stewart, Wm. L. Abbott, and B. M. Free, and finally, by eight patients in the University Hospital, in doses of  $\frac{1}{10}$  to  $\frac{1}{20}$  of a grain, and in five cases of violent mental disease, in doses of about  $\frac{1}{100}$  of a grain.

"The clinical results which, so far, I have had with this drug in cases other than maniacal, are very meagre, but so far as they go, are correspondent with the physiological results, which indicate little value for the relief of pain, but much for the removal of spasm."

In the next number of the same journal, Dr. Wood gives a very favorable report of this drug, made to him by Dr. Charles P. Henry, in charge of the Philadelphia Institute for the Insane.

"If there be any symptom which more than another, is characteristic and important in insanity, I conceive that sleeplessness is such. The broadest of therapeutical indications for an injured member or organ is rest. Any drug, therefore, which is a genuine addition to our soporific armamentarium, must be of interest to the medical man charged with the treatment of brain disorders."

"Chloral and the bromides are bulky and offensive to the taste, and many a lunatic will refuse to take them. Morphine, from its readiness of hypodermic use, is serviceable, but is very often contraindicated; and, besides the resistance on the part of the patient, whilst the injection is being given, is very objectionable. For all such cases, hyoscyne is of extreme value. Its minute dose, its tastelessness, makes it capable of admixture with palatable articles of food or drink which would be taken by any patient, except, of course, one who was starving himself, and, for such, it can be injected beneath the skin perhaps more readily and with better results than can morphine. In nearly all the cases in which I have used it, its efficacy has been clear.

In a case of sub-acute mania and in one of acute melancholia 1-48 grain in a little whiskey and water at bed-time gave about six hours' sleep, and marked improvement in the symptoms followed. In other cases it was given subcutaneously and with very striking results. In two cases of destructive mania the injection of 1-96 grain produced drowsiness in from forty to fifty minutes and natural sleep in one and a half to two hours, lasting from five to seven hours, and succeeded by a drowsy stage. Numerous trials were made with the drug in these cases with good results. In a case of destructive dementia the specific effect of the salt (1-96 grain) was slight, it produced great muscular lassitude and the patient's destructive propensity in a great part disappeared. In a case of destructive idiocy 1-96 grain had little effect, but 1-48 grain brought on, after seventy minutes, a profound sleep lasting for six hours.

As regards the constitutional effects, no marked depression of the pulse rate was noticed except in one case when after 1-96 grain, the pulse-rate was lowered from 84 to 48 in two hours' time, the respirations fell from 22 to 18. The extremities became quite cold and the circulation feeble.

No bad result of any kind has been observed to follow the use of the drug.

In commenting upon the relations between atropia, hyoscyamine and hyoscyne, Dr. Wood says that the last two are entirely different from one another, and that hyoscyne is essentially different from atropia.

Paraldehyde—of the drugs mentioned in last year's report, which act as hypnotics, this one seems to have been found useful by a number of practitioners, and among them Dr. Strahan<sup>2</sup> has had quite gratifying success with it.

"As a sleep-producer it stands in the same rank with

<sup>2</sup> The Lancet, January 31, 1885, p. 201.

chloral: while in anything like moderate doses it approaches in safety that safest of all sedatives, bromide of potassium. I have employed it over one hundred and fifty times in about twenty-five cases, and have found but two patients who did not respond to medium doses of the drug. One of these was suffering from acute mania, and the other from severe facial neuralgia. I have given it in mania, acute and chronic, melancholia, dementia, and various stages of general paralysis, during those periods of restlessness and sleeplessness so often met with in idiots and imbeciles, and in simple insomnia, and have found it almost invariably a certain somniferous.

Paraldehyde acts more quickly than chloral. When a dose is taken a feeling of warmth, a kind of grateful glow, is experienced, and the patient is often asleep within ten or fifteen minutes. When it does not produce sleep it does not excite, but rather tends to soothe and calm an excited or depressed patient. The sleep induced by paraldehyde is, I think, a nearer approach to natural sleep than that obtained by the administration of any other drug. No headache or other unpleasant symptom is experienced on waking, and the appetite is not injured even by the daily exhibition of the drug for considerable periods, in one of my cases for over three weeks.

The dose for men from thirty to ninety minims, but more than sixty drops is seldom required to produce sleep; and this, or even a smaller dose repeated within an hour, is much more effective than a single large dose. It is best given with a bitter tincture in sweetened water. It has a pungent taste, but a drachm when combined with fifteen drops of tincture of orange and an ounce or more of water sweetened with syrup makes a not unpleasant draught, never in my experience causing nausea or vomiting. The drug is given off principally by the lungs, and may easily be detected in the breath for twelve or more hours.

To sum up all that can be said in favor of this drug. It is an equally sure hypnotic with chloral, it does not in any case produce excitement before sleep, it leaves no headache nor other unpleasant symptom on awakening, and it does not affect the appetite. These are all matters of not slight importance, but there is one advantage which the drug possesses over chloral which at once gives it a place among our most useful hypnotics, and that is the absence of any depressing or paralyzing action on the heart; this absence of action upon the cardiac centre permits of its being given with perfect safety to general paralytics and others to whom chloral would only be given with the greatest caution and with constant anxiety as to the result even in small doses. The new drug may not take the place of chloral in everyday prescribing, but it must supplant it in those, unhappily numerous, cases in which the action of the sedative upon the heart is to be feared and yet where sleep is often so much to be desired.

Paraldehyde is still further endorsed as a sleep-producer for the insane, by H. C. Harris, M.D., in the *Medical Times* for May 16. In an experience with one hundred and fifty-two cases of mental disease he has found it the most efficient, safe, and reliable remedy, when a sleep-producer must be given for a length of time. After giving the drug for some time a certain tolerance is observed, but this tolerance does not seem to manifest itself sooner than when other hypnotics are used. Fifty minims is considered a moderate dose,

although seventy-five and in some instances one hundred minims have been given without the slightest effect upon the heart or respirations.

#### ANTIPYRINE.

Since this drug was noticed in a previous report it has been used in our own and other cities with, as a rule, good results. In some cases it has caused vomiting, and quite exceptionally its use has been followed by the appearance of an exanthematous eruption.

Dr. Leon Arduin<sup>3</sup> contributes a study of its physiological and therapeutic action, and after having studied it in a number of diseases he gives a general summary of its therapeutic action.

It is without doubt a certain and powerful antipyretic and acts as such without causing the unpleasant symptoms sometimes accompanying the use of quinine, and it diminishes the frequency of the pulse. It is eliminated by the kidneys, increases the amount of urine and diminishes the amount of urea.

The vomiting which is sometimes caused by it may be avoided by injecting a solution of it into the rectum. The most unpleasant result of its use is the profuse sweating caused by it which may continue for one-half an hour or an hour after its administration. To avoid this it is well to give the drug in small doses, twenty-five to fifty centigrammes.

The results of the study of its physiological action show that it influences without doubt the nervous system, especially the medulla and cerebrum.

As regards the circulation it seems most certain that its action is to diminish the force of the heart-beat, its influence on the blood pressure is not so definitely established, as some observers find this increased and others think that it is diminished.

On the respiration its influence is not great, and upon the urinary secretion its action is obscure.

How does antipyrine reduce temperature? This most important question cannot as yet be satisfactorily answered. Dr. Arduin believes that it is the result of a direct action of the drug upon the *thermogenic centres*. Antipyrine has been found to act as an excellent haemostatic.

Therapeutically the drug may be used in all febrile diseases where there is hyperpyrexia; in the more severe fevers such as typhoid, in pulmonary phthisis, the persistence of the fever constitutes a new indication. To avoid the production of excessive perspiration it should be administered in small doses. Only a physiological and clinical effect should be attempted; that is to say, it is not necessary to obtain a normal temperature.

Dr. Pusinelli<sup>4</sup> refers to a large number of writers who have used this drug in Germany, and summarizes the more important results of his work as follows:—

(1) Antipyrine acts in all cases, with the single exception of rheumatism, as a safe means of lowering the temperature through several degrees.

(2) The duration of the antipyretic action depends upon the state of the disease and the size of the dose. In severe febrile diseases one gramme acts for two or three hours, two grammes for four or five hours, and three grammes for about six hours.

(3) Before beginning the antipyretic treatment test doses of one half to one gramme should be employed.

(4) In severe febrile diseases, such as in typhoid

<sup>3</sup> Bulletin Journal de Thérapeutique, March 30, 1888, p. 211.

<sup>4</sup> Deutsche Med. Wochenschr., Nov. 10 and 11, March 1888.

fever, croupous pneumonia, erysipelas, etc., when the temperature is very high, doses of two grammes for men, one gramme for women, are indicated, and then only at intervals of an hour, and when the drug can be tolerated in doses of this size. In private practice it should be given every two or three hours. For complete deferescence four to six grammes a day are sufficient.

(5) In diseases with a temperature but slightly above the normal, in chronic diseases, especially in phthisis with hectic fever, it is often necessary to give only a single dose of from one to two grammes, in order to get rid of the fever for from six to twelve hours, or even longer.

(6) In the fever of acute articular rheumatism the remedy is sometimes contraindicated. An action on the joint disease was not observed.

(7) Against intermittent fever antipyrine is powerless; it is sometimes useful in cutting short the duration of the fever at its acme.

(8) In none of the diseases treated with antipyrine did it have a truly specific effect, as for example, quinine in intermittent fever. Still the course of the typhoid fever when treated with antipyrine is perhaps shorter and milder. In croupous pneumonia there is a marked improvement in the general condition and dyspnoea without any action on the local process in the lungs. Further in phthisis, especially with strongly remitting fever, freedom from fever of several days' duration with improvement in the general condition is often shown.

(9) As a rule antipyrine is well borne; collapse or chills were never noticed; pulse and respiration were not unfavorably affected; and on the kidneys the drug seems to have no harmful action.

(10) The only unfavorable symptoms were due to an occasional exanthema, vomiting and sweating. Vomiting was noticed especially in women, rarely in men. By giving the antipyrine in enemata the vomiting may be largely avoided, but it is sometimes even then to be noticed. The perspiration is only seldom unpleasant to the patient, and it may be overcome by the simultaneous administration of atropia.

(11) Over quinine antipyrine has the great advantage of ready solubility in water, and it is able to reduce high temperatures, so that for a long time a perfectly normal temperature can be had; this quinine cannot do.

(12) Compared with kairin and hydrochinin, antipyrine is to be preferred on account of its continued action on the fever, and as it does not cause collapse and chills.

#### DEATH AFTER THE USE OF ANTIPYRINE.

As we have seen, this remedy is one which may as a rule be administered without giving rise to unpleasant symptoms, although vomiting and an exanthematous rash may follow its use; collapse, in one or two cases, and a single death have followed its administration. An outline of what is given of the fatal case in the *Lancet*<sup>6</sup> is as follows:—

A woman of thirty-five who had miscarried in the fifth month. She had suffered soon after her miscarriage from pain in the lower part of the abdomen, vomiting, headache, and shivering, and later on from diarrhoea. She became progressively weaker, but

never lost consciousness. She was kept on milk diet, and the vagina was syringed.

She was sent to the hospital as a case of enteric fever. She was admitted to the hospital in a very weak state, six weeks after her miscarriage.

In the hospital the case was thought to be of a puerperal nature.

She was admitted on January 15th, was given five grains quinine three times a day. On the 17th the temperature was 103.6°, pulse 132, respiration 36.

On the 17th, at three o'clock in the afternoon, the quinine having been discontinued, she was given thirty-five grains of antipyrine, followed three hours later by seventeen and one-half grains.

The temperature at three o'clock was 103°, pulse 132 and very feeble.

At six o'clock the temperature was 98.4°, pulse 108, skin cool and moist. At eleven in the evening she answered questions intelligently and made her wants known; her condition was much the same as at six o'clock: temperature 98°.

On the 18th, after a restless night, with some diarrhoea and vomiting, the temperature was 98°, pulse 120. The patient much collapsed.

Stimulants were given, but the patient died at 11 p.m., thirty-two hours after taking the antipyrine.

The following is the result of an examination the day after death:—

Brain and its membranes much congested, the superficial veins being especially dilated, with a few hemorrhages. Pericardium normal, heart free from valvular disease, but somewhat softened; a few old adhesions of the pleura, but no excess of fluid. Lungs much congested, but otherwise normal. No peritonitis. Liver normal. Spleen much enlarged, weighing three pounds, and softened. Its middle third was occupied by a large infarct, broken down into a cavity in the centre. Kidneys also enlarged, and each contained two or three conical infarcts. Intestines intact in their whole length. Uterus contracted and empty.

In view of the very weak state of the patient and other conditions of the case given above, it does not seem necessary to fear antipyrine as in any sense a dangerous drug. It has now been used in hundreds of cases with only one fatal result; on the other hand it is imperative that every fatal or unfavorable case of a recent remedy should be widely known in order that the profession may be aware of all possible risks when they are using a new substance.

#### THALLINE.

This is also an antipyrine, one of many. Dr. Jakseh<sup>6</sup> gives a very enthusiastic account of a new drug which he has used in about eighty cases, but until it has had time to prove itself better than some of those now in use, it seems hardly proper to consider this aspirant for antipyrine power.

It is well to note in this connection<sup>7</sup> the views of Professor Nothnagel on the abuses in treating typhoid fever, and other fevers, on the theory that the fever is to be reduced at all cost. He considers fever one of those beneficent functions that are compensatory in their nature, and the interesting researches of Metchnikoff, according to which microorganisms are prevented from propagating themselves by an elevated temperature were referred to. A reduction or entire

abatement of the febrile temperature does not shorten the duration of a disease a single day.

#### ANÆSTHESIA BY CHLOROFORM AND AIR.

M. Aubeau,<sup>8</sup> in the hospital St. Louis, in the service of M. Peau, has used a mixture of chloroform vapor and air in 115 cases.

The proportions used were those suggested by P. Bert, 7 to 10 parts of chloroform vapor in 100 parts of air. The ages of the patients varied from eleven months to seventy years, and the duration of the narcosis from six to eighty-two minutes. For children seven parts of vapor in one hundred of air, were sufficient, but in adults the anæsthesia came on too slowly, and eight parts in one hundred seemed a better proportion. From 80 to 110 litres of this mixture were needed.

The advantage of this method seems to be that the first stage there is not irritation of the mucous membrane, and but little excitement was produced except in the case of those addicted to alcohol. Complete anæsthesia was produced in seven to eight minutes, and vomiting or coughing were seldom produced.

### Reports of Societies.

#### PHILADELPHIA PATHOLOGICAL SOCIETY.

MEETING September 10th, 1885. DR. J. HENRY C. SIMES, vice-president, in the chair.

DR. GEORGE DOCK exhibited to the Society a patient suffering from secondary epithelioma, and related the following history:—

The case occurred in the practice of Dr. W. W. Keen, of St. Mary's Hospital, to whom Dr. Dock acknowledges his indebtedness for the opportunity of recording it.

Mary C., aged 70 years, married, born in Ireland, applied for treatment November 29th, 1884. Her personal and family histories seemed to be unusually good. No traces of constitutional disease can be found. She uses alcoholic liquors in moderation and has smoked a clay pipe for the greater part of her life. Filling the right submaxillary region and extending up over the inferior maxilla, was a tumor, the distinct outlines of which included a space about three inches in diameter. The lower part was very prominent, standing out as a flattened node one and one-half inches in diameter and about three-fourths inches high, the whole height of the tumor being one and one-half inches. The growth was hard, immovable on the lower jaw; the surface was smooth and red, changing to a dull purple on the nodular elevation. On the summit of this growth was an opening leading upwards and inwards three quarters of an inch. The skin around the opening was everted and the surface of the crater-like cavity, covered with large and small granulations which exuded a thin, gray, offensive pus. The neighboring lymph glands were not enlarged. The general condition was good.

The patient stated that the growth first appeared six months before admission to the hospital as a "kernel" below the jaw. She applied various poultices and salves to it. The tumor grew rapidly for the following four months, when it opened, discharging a

large amount of pus; after that there was no apparent increase in size. The patient could assign no cause for the tumor, except a scald, received about one year before, on the lower lip near the angle of the mouth on the right side. This was followed by an ulcer, which was removed at the Episcopal Hospital in February, 1884. About two months before the appearance of the enlarged gland, Dr. J. M. Bradford, resident physician at the Episcopal Hospital, states that the ulcer was noted as epithelioma.

On December 2d, 1884, Dr. Keen removed the tumor together with a margin of healthy skin and the submaxillary salivary gland. The external plate of the inferior maxillary appearing roughened, it was cut away. The cavity of the mouth was not opened. By the use of hare-lip pins and sutures, the edges of the large wound, four and a half inches in diameter, were approximated almost perfectly. The dressings at first were carbolic; afterward iodoform was used. In the fourth week after the operation, a small, red, indurated, sometimes painful spot appeared in the skin, just posterior to the wound; a few days later the patient was discharged.

Microscopic sections made through various parts of the growth showed the structure of squamous epithelioma everywhere. The salivary gland was invaded. No trace of the lymph-gland could be found, and the supposition was that it had ulcerated away completely.

The patient was lost sight of until the beginning of May, 1885. She stated that after leaving the hospital, the small swelling alluded to, increased rapidly in size, and in a few weeks was larger than the one removed. She used no irritating measures, but the tumor broke down and ulcerated away, leaving a large granulating surface. On examination I found an ulcer on the side of the neck extending from one inch to the right of the median line to beyond the angle of the jaw, irregularly circular in outline, and containing islands of epithelioma. There was a small opening into the cavity of the mouth midway between the angle and the symphysis of the jaw, and just inside of the inferior border of that bone. The symphysis was drawn to the right about half an inch. There was a hard tender swelling on the gum above the inner edge of the opening, covered with small dark red nodules. In June the inferior maxilla was still more atrophied and had separated at the point of swelling and opening before mentioned. The adjacent ends of bone and gum were covered with a small fungous growth.

The process of atrophy and new growth is still continuing. The left alveolar process approaches the median line of the oral cavity and the point of the chin is on a line dropped from the outer angle of the right eye. The ulcer on the neck is healing, but the new growth in the mouth is rapidly enlarging, so that the tongue cannot be extruded. There are no enlarged lymph glands, but within a few days the patient has complained of pain in a gland in the subclavian region. The general condition is very poor; the patient lives on liquid food and takes morphia to produce sleep.

[The patient and the microscopic sections were then examined by the members of the Society.]

DR. T. D. DIXON exhibited the contents of a cyst recently removed from the back of a cow.

DR. GUY HISSARD exhibited a specimen of enlarged prostate. The specimen had recently been presented to the Mutter Museum of the College of Physicians by Dr. J. L. Stewart, of Erie, Penn., and

<sup>8</sup> Fortschritte d. Medicin, 1885, 121. Compt. rend. d. l. Soc. de Biol. 1885, 13 Mars.

was removed from a man aged seventy-five years, who, sixteen years previously had first come under Dr. Stewart's observation. At that time he was a strong, well-developed man, who had never been sick before in his life, but was then suffering from retention of urine, which had existed for seventy-two hours. It was found to be impossible to introduce a catheter owing to an enlarged prostate estimated to be larger than a hen's egg. Circumstances rendered it necessary to force an instrument through the gland, and five and a half pounds of urine were drawn off. A train of most unpleasant symptoms followed, and for weeks there was profuse suppuration with complete incontinence and great prostration. After about thirty days improvement began and continued to complete recovery. Three months afterward the patient seemed perfectly well.

Attacks of cystitis and retention became frequent, and for sixteen years only once did an interval of over three months pass without an attack, the usual time being about twenty days. During this time Dr. Stewart introduced the catheter 1194 times. Pain was intense during the later years when four or five ounces of urine had collected in the bladder. Meantime, the prostate continued to increase in size, and in November, 1884, was believed to be of the size of a large orange. On the night of the 27th of May, 1885, the patient had his last attack. Dr. Stewart not being at hand, two other physicians did not succeed in introducing an instrument. Just before 9 A.M. of the following day, the man was attacked with the most excruciating pain followed by a severe chill. At this time it is believed by his medical attendants that rupture of the bladder occurred, and the early date of this accident is accounted for as being the result of the contracted condition of the bladder. From this time there was no acute pain, but a severe aching followed by prostration. At 9:30 A.M. the bladder was aspirated, one ounce of urine coming away. Dr. Stewart catheterized him on the third day, drawing about a tablespoonful of urine. The patient died on the morning of the fourth day. His mind was clear and his voice strong to the last.

The *post-mortem* examination was not made by Dr. Stewart personally. It is stated that there was a rupture of the anterior part of the bladder near the fundus and that the cavity of the abdomen was filled with urine.

The specimens were not removed in such a way as to make this evident.

The specimen, as presented, consists of the prostate gland laid open by a cut in the vertical line and having attached to it the bladder, the walls of which have been cut in several directions. These walls are thick and have apparently undergone fatty degeneration, as had also the kidneys which accompanied the specimen, the pelvis of which were thickly overlaid with fat. The long diameter of the prostate, after being in alcohol for three months, is three inches; the shorter diameter two or three quarters inches. The third lobe is one inch long, from over-distention and through it the catheter passed and still remained in position. The bladder walls, when replaced, indicate a very small internal capacity.

DR. J. M. BARTON stated that but one case of rupture of the bladder from over-distention had come under his observation. It occurred in a German who had an impermeable stricture of eight years duration; no urine what-

ever passed; the contents of the bladder were removed several times by aspiration, while attempts were being made by filiform and other bougies to pass the stricture. As these failed, perineal section was suggested to the patient and his friends, but refused, and the doctor was told that they would send for him when they needed him. Three days later Dr. Barton was sent for; he proceeded to the house accompanied by Dr. S. W. Gross. The man was in a dying condition; the bladder tumor which before was very prominent had disappeared. Aspiration over the pubes and a trocar inserted by way of the rectum both failed to reach any urine.

On post mortem examination a small rent was found in the upper part of the bladder, but the specimen could not be secured.

In old cases of prostatic obstruction, Dr. Barton had several times found on post mortem examination that the patient had thrust the instrument through the "third" lobe; in one case several such openings had been made and had kindly healed.

The committee on morbid growths reported regarding Dr. Mitchell's specimen of cancer of the stomach exhibited at the last meeting in June, as follows:—

(a) *Stomach.* Microscopic sections across the wall of the stomach show an active proliferation of the epithelium of the mucous membrane, pushing its way into the wall, infiltrating it and forming alveolar spaces. The wall is further infiltrated with young cells, which for the most part replace the normal structure of the part. The process has probably been a chronic catarrh with great hypertrophy, passing gradually into a carcinomatous type.

(b) *Omental Nodules.* Sections of these show an indistinct alveolar structure filled with epithelial cells and a small celled infiltration of the adipose tissue. The appearances are those of a carcinoma, secondary, probably, to the growth in the stomach.

The committee reported regarding Dr. Nancrede's specimen of hamatocele of the testicle as follows:—

Sections exhibit layers of more or less well-developed connective tissue, through which are scattered numerous young connective tissue cells. No evidence of sarcoma tissue is present. The growth should be classed as a chronic connective tissue hypertrophy and as the sac contained blood the specimen is of chronic hamatocele.

#### AMERICAN GYNÆCOLOGICAL SOCIETY.

Tenth Annual Session, held at Washington, D.C. September 22, 23, and 24, 1885.

#### TUESDAY, MORNING SESSION.

The Society was called to order by the President, WILLIAM T. HOWARD, M.D., of Baltimore.

The Roll was then called, and the members of the Washington Gynecological and Obstetrical Society and other physicians present were invited to take seats with the Society.

#### ADDRESS OF WELCOME.

By SAMUEL C. BESEY, M.D.

MR. PRESIDENT AND FELLOWS:—I offer you the greetings of fellowship and bid you welcome, guests of the Washington Obstetrical and Gynecological Society. The acceptance of the invitation to hold your tenth annual meeting in this city, and your presence here to-day, confer a distinguished honor upon our

young Society, now just completing its third year of existence, and affords an opportunity for its members to meet and make the acquaintance of men, who, by their brilliant achievements in the sciences of obstetrics and gynecology, have won world-wide reputations, and added lustre and renown to American medicine.

We extend to you the hospitalities of fraternity, and, by our presence at this opening session, attest our professional regard and obedience to parental precept and authority.

It is a special gratification to know that the youngest of your natural offspring will enjoy the honor of commemorative union on this tenth anniversary of a society, which, in the past decade, has contributed so much to the advancement of obstetrics and gynecology, and to the cure and alleviation of the afflictions of woman.

On the roster of Fellowship, the names of Atlee, Buckingham, Peaslee, Sims, Trask, Wallace and White, are marked with the asterisk of death. Others have come to fill the places of the lamented dead, and the future gives promise of even greater progress and higher excellence in the aims of conscientious and scientific medicine.

Then, here, at the nation's capital, on this auspicious occasion, in the unity of a common purpose, let us join with you in that faith and devotion to duty which has been crowned with such marvelous success and rich rewards. You must lead; we will follow. And, when you have completed the labors of the present meeting, and the new and renewed friendships shall be interrupted by your return to the scenes of your daily work, if our gratitude as pupils shall be the measure of your pleasure as instructors, your second advent will not await the expiration of another decade.

The first paper was entitled

#### THE NATURAL HYGIENE OF CHILD-BEARING LIFE,

By SAMUEL C. BUSEY, M.D., of Washington, D.C.

The hygiene of pregnancy, said Dr. Bussey, relates to the preservation of the health of woman during those periods of her life-history intervening between conception and the commencement of labor.

With conception begins the existence of a new being, and during the succeeding period of intra-gestation, the product of impregnation passes through all the stages of development and growth from a fructified ovule to the complete organization of a being equipped for an independent life. Not only is a new being created, perfected, and endowed with the attributes of human life, but important and complex changes take place in the generative organs as well as in the entire organism of the mother.

These processes of transformation, development and growth are physiological; nevertheless, they are terminated by more or less violence and injury to both mother and child. The unavoidable mortality, however, is small. The death rate of lying-in women is too high to be accepted as the inevitable result of purely physiological and developmental processes.

The hygiene of pregnancy, the speaker said, has a much broader significance than a classification and detailed description of the disorders of pregnancy and the methods of prevention. In this wider range of investigation, the cycle of physiological and developmental processes during the reproductive age, demands equal, if not paramount consideration with the pathological disturbances of intra-gestation. The concurrent succession of natural phenomena and results which with

such uniformity subdivide the course of normal child-bearing life into epochs which distinctly mark the evolution, climax, and decadence of productivity, point with unerring certainty to the operation of general laws of the female economy. These laws must constitute safer guides of sanitation than the artificial method suggested by personal experience and observation. The hygiene of pregnancy must be considered as a natural science, based upon a knowledge of cause and effect and the laws of nature, if the highest success attainable is to be reached, and the author limited the discussion to the consideration of these fundamental principles.

Dr. BUSEY considered in sequence the processes of waste and repair, of growth and development, of organization and construction. He declared that there was no border-line of health. We cannot define where the physiological ceases and the pathological begins.

Puberty, matrimony, pregnancy, parturition, lactation, the post-pregnant restoration of ovarian activity, and the menopause, have each their physiological characteristics and may each be associated with a variety of pathological conditions. The speaker then paid a glowing tribute to Nature's care of her complex and beautiful handiwork and asserted that the natural causes of the diseases of pregnancy are few, the acquired, numerous and multifarious. The child-bearing period of woman's life, said the Doctor, begins at puberty and ends with the expiration of the years of maturity. Then succeed in continuous progression, those changes which mark the decline and decay of organic life. Nature's code of hygiene of pregnancy is not, however, limited to the later years of the child-bearing period. The fertility increases from the commencement of the child-bearing period until the climax is reached, and then declines to its extinction. The age of greatest safety of pregnancy coincides with the age of greatest fecundity. Beyond and under, the mortality increases with the increase and diminution of age, but the rate is higher with the increase beyond than with the diminution below the age of maximum safety or least mortality.

The manifest conclusion, said Dr. Bussey, from these general laws governing the child-bearing age is, that the age of nubility should correspond with the ages of maximum fecundity, fertility, and least mortality.

The speaker then went on to say that puberty and nubility are not simultaneous. He dwelt on the importance of the period of adolescence and deprecated too early pregnancies. He thought Nature prescribed the fifth quinquennial as the period during which the laws of fecundity, nubility, and survival find their natural complement in relatively highest gradation of perfection. He considered first pregnancies the most dangerous, and thought the danger increased by too early and too late primiparity.

The period of lactation, he said, is an important epoch in child-bearing life. He spoke of the gradual developmental and retrogressive changes in the mammary glands, and declared that to functional irregularities and derangements caused by artificial interference with the processes of evolution and involution must be traced many of the tumor diseases to which the mammary glands are so liable. The extinction of the procreative function in woman protects the remaining vital forces from the decay of coming age. If, however, the seeds of disease have been sown during the child-bearing period, the change of life may increase their activity.

The speaker then compared the mortality of epidemics with the aggregate of the mortality of child-bearing

in the same time and thought the latter greater. He believed the time would come when in this special department of hygienic custom, based upon the laws of life and nature would supersede the practices of the well meaning but misguided.

State interference might prove a dangerous expedient — more potent for evil than for good. Yet, if the age of majority of women could be made to correspond with the first year of the period of maximum fecundity, popular prejudice and love of custom, which have popularized the age of majority as the minimum age of nubility, would, sooner or later, conform fashion to the law. But the age of majority should not be too far advanced.

Spinster matrimony, he contended, finds its protection in the decadence of fecundity and fertility; in the increasing incapacity of the uterus to carry an ovum, with longer disease; and in the greater disparity in the ages of the bride and bridegroom. Beyond these immunities the consignment to suffering and death must follow the law pertaining to the later years of reproductive life. He spoke of the instinctive dread of spinster life and the intuitive designation of thirty as its initial year.

He deprecated precocious matrimony, and considered it the sequel of precocious puberty. Moreover, he said, if it entails harm, the root of the evil must find its radicle in too early puberty. In this country, and in the higher walks of life, the ratio of precocious puberty is manifestly on the increase. Whether equally so among the middle and lower classes he did not know, but if not, it soon will be, because the sedulous cultivation of the faculty of imitation is rapidly oblitterating class distinction.

In this, as in other departments of medical science, the discovery of abuses is far more easy, said the speaker, than the ascertainment of cause and the application of correctives. Whenever medicine confronts popular prejudice, established habit, and the instinctive beliefs of woman, it encounters obstacles not easily surmounted. The aesthetic obligations of civilized society and the masterly antagonisms of human depravity bid defiance to medical science and the laws of nature. If, then, he said, I suggest that precocious puberty is one of a series of grievous evils growing out of the organization of society, you will be prepared for a confession of failure to point out a method of reform.

#### DISCUSSION.

DR. CHADWICK, of Boston. — I have made a few investigations in regard to the early appearance of menstruation with reference to women of various nationalities in this country. In the examination of over four thousand cases it was found that American women menstruated earlier than women of other nationalities examined. Furthermore, American women of American parentage began to menstruate earlier than American women of foreign parentage. Scarcely enough observations in reference to the menopause have been made to justify absolute conclusions, but I find to my surprise that the menopause is appearing later in American women. If this is corroborated, the conclusion would be that the child-bearing period is greater in American women than in women of other countries. The fact that the child-bearing period is increased both at the beginning and the end, I should take as an indication of added vigor. There is no

question of the fact that the number of children to a family is diminishing, but this can be accounted for by social influences, and is common to all civilized communities.

DR. REYNOLDS, of Boston. — I agree entirely with the statement made by the last speaker, and I believe that in the community in which I live, the women of the upper and middle classes menstruate earlier than they did twenty-five years ago. I believe that this indicates an activity of function which will prolong it beyond the average period of cessation.

A point of interest is in reference to the diminution of sexual power. I question whether this is not more dependent on individuality than on sex. This is, however, a most perplexing and obscure question.

#### PUERPERAL DIPHTHERIA.

By DR. HENRY J. GARRIGUES, of New York. — This is a disease not referred to in the majority of text-books. It is one of the forms of puerperal fever, or rather one of the different diseases included under that term. It is distinguished by the appearance of diphtheritic exudation somewhere in the genital tract of the puerperal woman. It is accompanied by well-marked general symptoms, imperils life, and calls for active treatment. The paper is based upon twenty-seven cases treated in hospital practice and two cases occurring in private practice.

#### PATHOLOGICAL ANATOMY.

The characteristic feature of the disease is the diphtheritic infiltration which is usually of light pearl-gray color. Generally appearing in small spots and coalescing or extending by involving new areas. The exudation is firmly adherent to and imbedded in the underlying tissue. It is most marked at the points where the canal becomes narrow. This may be explained by the more frequent occurrence of lacerations at this point. The posterior wall of the vagina is more commonly attacked than the anterior wall, which is probably due to the fact that it is bathed with the discharges from the uterus. The exudation may, however, appear on entirely healthy portions of mucous membrane, which have not been the seat of laceration. The surrounding parts are more or less swollen. The connective tissue of the pelvis is infiltrated with serous fluid, and is sometimes the seat of ecchymosis. The skin is sometimes the seat of a dusky erythema, consisting of minute spots, disappearing on pressure and not elevated. In one case petechia as large as hempsed existed. These were not affected by pressure. The same patient later developed erysipelas.

In five cases, ending fatally, autopsies were made. The uterus was much enlarged, sometimes reaching almost to the umbilicus two weeks after labor.

The cervix may be torn, showing diphtheritic patches or a thin gray film. In two cases, large portions of the cervix sloughed and the vagina became gangrenous. The tissue of the uterus is friable and may be almost difficult. The diphtheritic exudation may affect the Fallopian tubes. In some cases the muscular tissue of the uterus is scooped out as in dissecting typhus, of which I have described several cases. This occurred in four of the cases of puerperal diphtheria. In one case the mass thrown off was four inches long, two inches wide, and one inch thick. These masses have a pear shape, their outer surface is of a gray color, the inner surface flesh color. They

are perforated with a number of holes leading into uterine sinuses. Under the microscope these masses are shown to consist of smooth muscular fibre in a more or less advanced state of fatty degeneration. The connective tissue is increased. Lesions were also found in other organs and occasionally in the joints.

Difficult labors and a previous weakened condition of the patient predisposed to the development of the condition. The real cause of the disease is, however, an infection from the outside. I have never been able to convince myself that the poison passed from one patient to the other, but it seems to be in the air of the ward. When a ward has been fumigated with sulphurous acid there would not be a seriously sick patient for weeks. That the poison coming from the outside is also shown by the fact that when the prophylactic treatment, to which I shall refer, is adopted, the disease does not develop.

The first symptom which shows a deviation from a normal course is usually the occurrence of fever, which mostly appears from two to four days after delivery. Sometimes there will be a chill or chilly feeling. The temperature rises gradually, as a rule. It has ranged from  $100.6^{\circ}$  to  $107^{\circ}$ , the average being from  $102^{\circ}$  to  $104^{\circ}$ . Anorexia, vomiting, coated tongue and diarrhea witness the disturbance of the gastrointestinal canal. The patient complains of pain in the epigastrium and one or both groins, sometimes extending into the legs. Examination shows the uterine larger than it should be, and quite tender. Tenderness is often also found in the groins and some swelling may also be observed. The lochial discharge is often scanty and offensive, but in some cases it has been normal. In those cases in which there was expulsion of the tissues of the uterus, there has been a purulent discharge until expulsion has been accomplished. The diphtheritic patch commonly appears from three to seven days after delivery. It continues to spread for several days, and usually stops in from three to eight days after the beginning of treatment. In one case the diphtheritic patches also appeared on the tongue, indicating that the disease is identical with the ordinary form of diphtheria attacking the throat. The irritation of the nervous system is evidenced by headache, stupor, and delirium. There is alteration of the renal secretion, and sometimes there is painful micturition. Three patients had albuminuria. In two cases jaundice bore testimony to the perverted condition of the blood. The sweet breath and profuse sweats of septicæmia were observed twice. One patient developed painful arthritis of the elbow joint. When once the diphtheritic process was arrested, the patients recovered rapidly.

There is scarcely any difficulty in the diagnosis. When the injections of bichloride of mercury are employed, they cause a yellow discoloration of abraded surfaces. This is strictly limited to the abraded surface, and is unaccompanied with general symptoms. When the chloride of zinc is applied to the affected surface in the treatment of the disease, a slough is caused, having the color of the deposit, and the physician is sometimes at a loss to determine whether or not the disease is spreading. The point is decided by noting where the application is made and by observing the edge of the deposit. The diphtheritic deposit has a scalloped outline, while the outline of the slough is smooth.

As to prognosis, five out of twenty-nine cases

died, giving a mortality of 17.2 per cent. Another of the cases might have survived, for she lived thirty-two days and died from rupture of the uterus while an assistant was using an intra-uterine injection. The post-mortem showed the walls of the uterus to be extremely thin. The duration of the cases ending in recovery is usually about two weeks. In those cases in which a portion of the uterus is scooped out the organ is left in a weakened condition, which in future pregnancies may predispose to rupture of the uterus.

In the way of prophylaxis, it is recommended to limit the vaginal examinations during labor as much as possible. The finger or hand should not be introduced into the uterus unless absolutely necessary. The delivery should be so accomplished as to avoid as much as possible wounding of the genital canal. Instruments should be used with care. The most important element in the prophylaxis is the use of bichloride of mercury as an antiseptic. Everything coming in contact with the patient should be washed in the solution of corrosive sublimate, one to two-thousand. After this treatment was introduced only one case appeared in six months, and that was due to carelessness on the part of a resident who delivered a woman immediately after removing a macerated fetus from another patient.

After the disease appears the treatment must be energetic. The only treatment that has given me satisfaction is that with chloride of zinc. The affected parts are touched with a solution consisting of equal parts of chloride of zinc and distilled water. This is rather painful, and an anæsthetic may be used. A warm solution of corrosive sublimate, one to two-thousand, is used for intra-uterine injection where this is required, and subsequently a suppository of fifteen grains of iodoform is introduced. If this is done the process need not be repeated more than once in the twenty-four hours. The vagina is to be douches every three hours. The parts should be examined every day, and if the process is not arrested the chloride of zinc is to be repeated. If the disease is limited to the vagina and vulva, the intra-uterine treatment is omitted. Extract of ergot is also given, with the hope of causing contraction of the uterus. Morphia, quinia, and digitalis are used as indicated. High temperature is combated with sponge-bathing, salicylic acid, and, if necessary, the rubber coil and ice-water. Carbolic acid is also given, sometimes combined with the compound tincture of iodine. If the temperature is not very high, warm poultices are preferred to the ice bag and coil. Where there is diarrhea, warm poultices are also considered preferable.

Samples of the occlusion bandage, to be used after labor, were exhibited. They consisted of a pad of absorbent cotton wet with the corrosive sublimate solution, over this a piece of oiled muslin or rubber cloth, and over all another piece of absorbent cotton and a piece of muslin or flannel to attach it to the binder.

#### DISCUSSION.

DR. Lusk, of New York. — Ten years ago I had 150 cases of this affection under my care, of this number twenty-eight died. The epidemic could be traced to a patient brought into the hospital after a long labor. She was suffering at the time from syphilitic ulcers of the vulva, which was excessively inflamed. I extracted the child with forceps and the inflamed

perineum tore. Soon after this the diphtheritic deposit appeared, and the whole ward was infected. The first cases were the result of transference from the patient, for the question of contagion was not recognized as it is now. After a time great care was taken to avoid every possible source of contact, but the disease continued and could be only explained on the supposition that the air of the ward was filled with germs. In my first cases the treatment consisted in the application of equal parts of the solution of the persulphate of iron and compound tincture of iodine. The disease usually began with a certain amount of mildness and gradually became more severe. Of the first twelve cases only two died, while in the second set of twelve cases only two recovered. In the progress of the epidemic the entire system seemed to be affected, even before the advent of labor. Since the adoption of Dr. Garrigues' suggestion, with reference to the use of corrosive sublimate injection, I have not seen a case of puerperal diphtheria in the course of three and a half years. I have neither had a death from fever nor any cases of fever, the old-fashion milk fever even being absent.

Dr. WILSON, of Baltimore. — I have always been adverse to using bandages of any kind after delivery, preferring to have the napkins placed under the patient so as not to obstruct the free flow of the discharge and to use frequent washing of the vagina with antiseptic solutions.

Dr. RICHARDSON, of Boston. — During 1882 and 1883, I spent most of my time fighting this puerperal fever with ill success, until the appearance of Dr. Garrigues' paper. After adopting the use of the pad and the corrosive sublimate solution for the hands of the attendants and nurses, the hospital has been entirely free from the disease. There has been no death since we adopted these measures and there has been only one or two cases which made us at all anxious. I agree entirely with what the reader of the paper has said.

There is one point in regard to the use of the corrosive sublimate injections. I have found that even so weak a solution as one to five thousand will sometimes cause salivation. Where I meet with this I use iodoform as has been suggested.

Dr. BURNS, of Brooklyn. — I would inquire of Dr. Garrigues whether he has noticed any vaginal deformity following this affection? I have seen one case in which such deformity occurred. A lady, after her fifth confinement, was taken with tenderness, fever, and so on, and on the fourteenth day had a copious hemorrhage. On examination, I found the entire posterior and outer surface of the vagina almost completely detached. Acetic acid was applied and the bleeding checked. An examination after the healing of the parts had taken place, showed the vagina much shortened and narrowed in its upper part, the cervix being obliterated. The anterior portion of the cervix was in contact with the recto vaginal septum. I told the patient in reply to her inquiry that it was not likely that she would conceive. My prediction turned out to be false. In the following confinement, she was in labor twenty-four hours before there was the slightest appearance of an opening through which a fetus could escape. There was bulging of the presenting portion of the uterus, and into this I made an incision and the child was delivered readily, the patient making a rapid recovery.

Dr. GARRIGUES. — I think that the endorsement of Drs. Lusk and Richardson would be sufficient to induce others to try the occlusion pads. During the year preceding the introduction of the new method of treatment the mortality was nearly seven per cent. During the next, with the new method of treatment, the mortality was one and a half per cent. During the second year, it was less than three-fourths of one per cent. In the institution in which these observations were made there are a number of disturbing elements, one of the most important being its connection with a large general hospital. In this new method of treatment the antiseptics are applied only to the outside in normal cases. Only in abnormal cases are vaginal and intra-uterine injections employed.

In reply to the objection of Dr. Wilson, I would say that the pads used are absorbent. In hospital practice the pad is changed every four hours. In private practice, three times a day is sufficient.

I have never had salivation from the use of corrosive chloride. The nearest I have come to it has been fetid breath and diarrhoea.

I have only seen two of the cases subsequently to recovery when in labor. In one there was great shortening and narrowing, but during pregnancy there was softening, and the labor was quite easy. The second patient is pregnant, and the vagina appears to be in good condition.

In reply to a question, the speaker stated that the use of the pads, prevents all offensive odor.

#### AFTERNOON SESSION.

The first paper was that of Dr. Joseph Tabor Johnson, entitled,

#### FOUR CASES OF OÖPHORECTOMY, WITH REMARKS.

CASE I. Miss M., had suffered severely from chronic oöphoritis and menstrual epilepsy. She was at this time twenty-nine years of age and had suffered for fourteen years. There was constant pain in both ovaries, but most of the suffering was on the left side. For two weeks out of every month she was under the care of an attendant, her education had been neglected and she was in an almost beastly condition. She had been under the care of skillful physicians, and almost everything had been tried. Oöphorectomy was therefore decided upon and performed August 17, 1882. Both ovaries and one fallopian tube were removed. For several months she had no period and no spasms. Gradually her menses returned and with them the convulsions in milder form. She is now menstruating with more regularity than before the operation.

CASE II. Miss W., age twenty-one, from being in alliance she had been reduced to the necessity of earning her own living. Five years before coming under observation she took a severe cold at the monthly period. Since then she has suffered from chronic oöphoritis. She also had leucorrhoea and a displaced uterus, for which she was treated without material benefit. I treated her for three months without benefit, and then removed the ovaries. She made a rapid recovery, and has since been free from pain.

CASE III. Miss S., age twenty-four, had been a great sufferer from dysmenorrhoea and reflex symptoms. She suffered with burning pain in the abdomen and head for ten days preceding menstruation. For several months there had been no flow, but the distressing symptoms continued. Both ovaries and tubes were re-

moved. She made a rapid recovery, and continues healthy.

CASE IV. Mrs. —, age forty, the mother of three children, had suffered with pain in the left ovary for twenty years. She had a lacerated cervix and perineum which had been restored without improving the other symptoms. She had been under treatment for ten years, but was practically bedridden for three weeks out of every month. She wished to have the ovaries removed, but I advised her to wait five years longer until the menopause would accomplish the same result. She however insisted on the operation, and I performed it last February. She did well for three days, when vomiting set in and she died exhausted on the sixth day.

The speaker then referred to the great importance of an early diagnosis in such cases in order that the operation might be performed before numerous adhesions had taken place and before the general condition had become so depressed, referring to the statistics of various operators in confirmation of his statements. He thought that many cases which are now lost from prolonged operations necessitated on account of the numerous adhesions, might be saved if there were means by which an early diagnosis could be made.

#### DISCUSSION.

DR. R. S. SUTTON, Pittsburg.—We all admit that a woman with a cystic tumor of the ovary is doomed to death, if the tumor is not removed, but when she is suffering from some disease of the ovary which does not give tangible evidence of its presence, the surgeon has often difficulty in deciding as to the question of operation. It may be that under ether and with bimanual palpation it is utterly impossible to detect any evidence of disease of the ovaries or tubes, and yet the ovaries may be at the bottom of the trouble. Is the woman to be allowed to go on suffering because we cannot obtain evidence of disease that will justify an operation? It is better to give the woman the benefit of the doubt and open the abdomen and examine the organs. I do not believe that any one can tell the exact condition of the ovaries before opening the abdomen. It has now come to be the practice in obscure conditions in women for which no explanation can be found and in which it is probable that the ovaries or tubes are at fault, to make an exploratory operation. As a rule exploratory operations are safe. I have yet to open the first abdomen and fail to find disease of the ovaries or tubes.

Here is a specimen which I removed from a woman sent to me for operation for a lacerated cervix. There were symptoms which I could not refer to the conditions of the cervix. On careful examination, I found evidence of disease of the ovaries. I removed both ovaries, one contained a dermoid cyst and the other had undergone cystic degeneration.

DR. BAKER.—This operation opens up a large field of usefulness to the gynecologist and of benefit to woman, but there is great danger of the pendulum swinging too far and the operation being performed too frequently. I would not discourage the operation in properly selected cases. An operation which gives such brilliant results in properly selected cases is almost certain to be carried too far. The greater skill is shown in curing these patients without the removal of organs. We shall come to a better understanding as to when the operation should be performed and when

not, by studying the organ itself very carefully in those cases in which it has been removed. In all descriptions of the operation, there should be an accompanying report of the microscopical examination.

The question of early diagnosis has been referred to, and this is a matter of the greatest importance. The ovaries and tubes are not the easiest organs to examine. Even where the ovaries are adherent to surrounding tissues it is often extremely difficult to determine this fact. Exploratory operation may be the only way of determining this fact. Where exploratory incision has been made and the organs found healthy so far as their gross appearance is concerned, I say that they should be put back and the abdomen closed, even if the woman suffers excruciating pain with the menstruation. I believe if the same perseverance and good judgment was manifested in these cases as in others, we should be able to cure many of them without operation.

I cannot agree with the author of the paper in regard to the increased danger from the presence of adhesions. The only death that I have was in a case where there were no adhesions, and the operation was performed with ease. In many of the other cases there have been extensive adhesions.

DR. EMMETT, of New York.—What I have to say is rather in the form of a protest. I am not an advocate of the operation, and I think that more harm than good has been done by its performance. There are cases where the operation must be done. Where there is salpingitis, with the tubes filled with pus, the operation is certainly indicated. That the operation should be done, as it frequently is, for the relief of so many symptoms, is I think, a reproach on the profession. I cannot advocate the opening of the abdomen for the purpose of making a diagnosis. If the diagnosis cannot be made beforehand, I do not think it justifiable to run the risk of opening the abdomen.

For three years, I have been looking for cases in which I considered the operation indicated, and I have seen but two such cases. One was a typical case in which there had been several attacks of peritonitis following gonorrhoea. I found both tubes as large as my wrist and presenting the twisted appearance described by Tait. The history indicated the existence of pus. I urged an operation, but the patient refused. She was seen by Dr. Thomas, who also recommended operation. She insisted upon staying in my private hospital. For five months there was no improvement. The treatment consisted of hot water injections, keeping the bowels regular, applications of iodine daily, and attention to the general health. After several months, the tubes began to diminish in size, and in the course of a year the accumulation entirely disappeared and she left the hospital apparently a well woman.

The second case was similar. She also refused an operation. She is now no worse and in some respects better than she was some years ago.

DR. LISK.—Great caution must be exercised in the performance of this operation. I recently saw a lady who had pelvic inflammation following the use of the stem pessary. There is now thickening of the broad ligaments. She visited a gynecologist who advised the removal of the ovaries. I can find no evidence of disease of the ovaries or tubes. In many of the operations which I have seen there has been no evidence of disease in the ovaries or tubes removed. I do not condemn the operation. I have operated in four cases in

which there was distinct evidence of disease of the tube, with good success.

DR. WILSON.—I think that many cases have been operated on which should have been left alone, but there are many cases which nothing but an operation will relieve.

DR. E. W. JENKS.—I am aware of several cases in which the operation has been performed without benefit. Where the ovaries and tubes are diseased, there can be no question as to the propriety of its performance.

In many of these cases of so-called hystero-epilepsy, which are often nothing more than hysteria, I consider the removal of the ovaries and the stopping of the prospect of the patient becoming a mother, a positive wrong. The exploratory operation is not free from danger, as I know of four deaths under these circumstances in which no disease of the ovary was found.

DR. T. A. REAMY, of Cincinnati.—One woman was sent to me with dysmenorrhœa and hysterical symptoms with the request that I should remove the ovaries. It was a well marked case. Five months treatment of the cavity of the uterus with change in her surroundings and general treatment resulted in entire recovery. I have had several other striking cases.

It is the exception to find the ovary healthy in women after the age of forty. I have been making these observations for ten or twelve years.

DR. EMMETT.—This operation is sometimes done for dysmenorrhœa. I think that it should never be done for this condition. I consider dysmenorrhœa a neuralgic condition, the result of anemia. When the dysmenorrhœa is relieved by operation, it is because the general nutrition is improved by the removal of the ovaries.

DR. SETTON.—I agree with Dr. Baker that where in an exploratory operation, the ovaries and tubes are found to be healthy, that they should not be disturbed.

DR. MAXX.—Dr. Emmet has made the statement that dysmenorrhœa is a neuralgic condition and is not an indication for the operation. Although it may be neuralgic, I think that the neuralgic condition may become so firmly established that it cannot be relieved without taking out the seat of the neuralgia. In two such cases I have thought the operation indicated. In one the patient was free from pain only three days of each month. I advised the operation, which was performed by Dr. Clark of Niagara. The patient completely recovered.

The second case was my own. The woman had suffered for a number of years with excruciating pain. The ovaries were enlarged and tender. The whole abdomen was tender. The ovaries were removed and the patient entirely recovered her health. I cannot admit that there are no cases of ovarian dysmenorrhœa which can be relieved by the operation. I however think that they are rare.

DR. JOHNSON.—I did not recommend the operation except under well marked indications. I agree with those who fear that the operation may be performed oftener than necessary. Its use in nervous and neuralgic conditions is not always as beneficial as in some other conditions, as myoma of the uterus for example.

To be continued.

—The Lynn Hospital is being enlarged at an expense of \$1,000.

## Medical and Surgical Journal.

THURSDAY, OCTOBER 1, 1885.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly, by CUPPLES, UPHAM & CO., Boston. Price, 15 cents a number; \$5.00 a year, including postage, to subscribers in the United States and Canada. Foreign subscribers are charged the postage in addition.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.*

CUPPLES, UPHAM & COMPANY,

283 WASHINGTON STREET, BOSTON, MASS.

### THE BOSTON WATER SUPPLY.

The Boston Water-Supply was formerly supposed to be one of the best and purest in this country. It may very possibly have been such, it certainly has not been such during the last six or eight years. The defilement of Pegan Brook by the inhabitants of the town of Natick, the pollution of Beaver Dam Brook and of Course Brook, by the town of Framingham, and the Women's Prison at Sherborne respectively, and of Farm Pond by the Framingham Station of the Boston and Albany R. R., have introduced sources of disgust as well as of positive danger into the Lake Cochituate and Sudbury River supplies, which have been clearly recognized but only recently proceeded against with any degree of vigor.

With the incorporation of Charlestown within the city limits, another source of supply, that of the valley of the Mystic River, was accepted, burdened with equally serious drawbacks. The water-shed of the Mystic is a very thickly-populated district, in which the extensive tanning industry finds its home. The drawbacks incident to the Mystic supply have long been patent, but have been allowed to continue with very little interference or supervision since the building of an inadequate sewer to remove waste products—either because it was supposed this source of supply would be given up, or because the offending interests were too complicated or too powerful to be dealt with under the existing laws. The Legislature having two years ago amended the law so that these cases of pollution are now referred directly to the court for a decision instead of to a jury, there is more encouragement to invoke legal protection, and of this advantage was promptly taken by the late Water Board. The best protection, however, in these questions of water-supply and drainage, which are among the most important and difficult our thickly-settled communities will be called upon to face, must be found in an enlightened and intelligent public opinion and conscience.

It is not a question of the welfare of any one individual or of any one community at the expense of others, but all are concerned in the happy solution of these problems of pure water and good drainage.

The consequences of an epidemic of typhoid fever, of cholera, of diphtheria, make themselves felt directly and indirectly in a hundred ways, far beyond the immediate centre of the affliction—whether that be in a crowded city, in a populous town or a sparsely-settled country district. It is the old fable of the belly and the members in a modified form.

Public attention has been called again to this subject by the appointment, last May, of a committee of the Suffolk and Norfolk District Medical Societies to visit the sources of water-supply of Boston, and report the result of their observations.

An informal report of these investigations from the secretary of this committee to the Mayor of the city found its way into the daily press, having been referred by the Mayor to the Water Board, and has given rise to animadversions and comments from various quarters; the most satisfactory and important sequel, however, being a concise and business-like report upon the subject from the Water Board to the Mayor of Boston, the Board having promptly obtained a list of the various points of pollution and entered upon the task of abating them as far as lies in its power.

There is therefore fair ground to suppose that the disinterested action of these medical men will not be without some practically useful results. But we must confess it would have been probably more effective, and certainly more acceptable if it had come before the public in the form of a simple statement of the existing facts—and possible consequences—which can neither be questioned nor denied. Those who offer such a statement deserve well and only well of their fellow citizens. It may be left to individuals to advocate pet theories, and to the responsible authorities to devise remedies.

Though we know only too well that the ideal is scarcely attainable in the water-supply of a large city, that is a poor reason for not struggling toward it. One thing is pretty certain, and should be borne in mind by the public, that drinking-water may receive and convey the poisons of such diseases as typhoid fever and cholera, and yet neither the chemist nor the microscopist be able to detect them. A chemical examination may sound the note of warning, but cannot give assurance of entire safety. On the other hand the most stinking water is not necessarily the most dangerous, for a water with comparatively little or no odor may carry in a larger measure the possibilities of future harm.

A State Commission has for some time had under consideration the general question of the disposal of sewage as a protection to water-supplies. It will report to the State Legislature at the beginning of the coming year. It is to be hoped this commission may see its way to recommend measures at once theoretically sound and practically feasible, and such as may commend themselves to the wisdom of the Legislature. In the meantime the city of Boston, and other neighboring cities and towns are exposed to risks which they may continue to run with impunity, but which are by no means imaginary.

It is idle to pretend that the inhabitants are proud of the water furnished them by the city of Boston as a beverage—though certainly very much better than it has been in the past—when a dozen or fifteen different spring waters find a profitable sale through the streets.

#### SUMMER INSANITATION AND AUTUMNAL FEVERS.

WITH the returning summer tourists, are coming back to the cities the train of invalids which experience teaches us but too well to look for among those who have been astivating at many of the country and seaside resorts.

Cases ranging from the lighter diarrhoeal disturbances up through febrile attacks of varying degrees of severity to well-marked types of typhoid are met with, to be sure, throughout the summer months, but as the nights grow cooler and the sun's rays less direct the character of the maladies becomes more serious and the typhoidal elements more marked. It is, therefore, by no means a rare experience that the first use to which the long-closed city house is put on its reopening is that of a hospital for some of its unfortunate occupants. Besides the annual crop of abdominal fevers which, like other products of the soil, ripens in the autumn, diphtheria, which knows no season, sometimes reaps a fearful harvest when large numbers of children, as for instance in one of the summer hotels near Boston, have been brought within the range of some source of infection.

It is generally recognized by the public that the domestic sanitation of the great majority of country houses is very defective, even for the usual number of occupants of these houses, and is therefore almost sure to be inadequate when the number of the occupants is doubled. Yet it is safe to say that in selecting quarters for the summer hardly one person in ten extends his investigations into the sanitary conditions of his proposed domicile, further than by a general question if the drainage is "all right." The eligibility and accessibility of apartments, the table, the scenery, and the society engross all the personal inquiry of the applicant, and if unsavory odors and disagreeable water make themselves noticed after a few days they are dismissed as temporary annoyances that must be put up with. One can't expect during his summer pleasuring, to have all the comforts of home, it is said. The consolation that it is only for a few days or a few weeks may be applied to any other disadvantage of the summer abode. But to drainage and water-supply the word "temporary" is not applicable, any more than to a dose of poison. However ephemeral the exposure, the results may be permanent.

Yet this carelessness in the selection of the summer house is by no means to be wondered at in those who pay so little attention to matters of sanitation even in their permanent residences. The verbal assurance of the enterprising agent as to the state of the plumbing, together with bright stop-cocks and a high polish on the wood which carefully sheaths all the pipes from

sight, is enough to satisfy the average purchaser or tenant, and provided the rooms are sufficient in number, size, and dimensions, the bargain is completed. As has been said, no prudent man would think of buying a piece of property without securing a perfect title thereto. And while no one grudges the fee paid to a competent conveyancer for the assurance that the money invested will not be thrown away, very few think it worth while to obtain the opinion of the sanitary expert as to the security for the life and health of the occupants of the house.

Of course it is to be admitted that no amount of caution will avert all cases of zymotic infection. Persons have occupied the same house in perfect security for many years only to fall victims at last to the unperceived breaking of a pipe or a cesspool. An exceptionally rainy season may carry surface water into a spring never before thus contaminated.

The vicissitudes of travel may unavoidably expose one in more than a single sense to the "perils of waters." But it seems reasonable to believe that a not inconsiderable part of these maladies which form such a gloomy addition to the holiday season might be avoided, if people would only exercise in matters of sanitation some of the caution which they show in the other affairs of life.

#### AN ANTI-VACCINATION RIOT AT MONTREAL.

THE repugnance of the French population at Montreal to vaccination and isolation as protection against small-pox at last forced the authorities into making both measures compulsory, and this step has just been followed by a riot. Monday morning a mob attacked officials putting up placards on houses and the office lately opened in the east end by the Board of Health, and demolished the windows. That night an immense crowd demolished the glass in the *Herald* office on Victoria Square, the paper having advocated systematic vaccination and revaccination. They also peppered all the windows of the City Hall where the central health office is situated, doing much damage there. Their next movement was on the private mansion of Alderman Grenier on St. Denis Street, who is obnoxious as a member of the Board of Health. They smashed his windows, and at a late hour have proceeded to demolish the windows of the city medical official vaccinators, all of whom are French Canadians, in the east end. The damage on the whole is very large, and must be paid by the city.

The mob set fire to a quantity of slayings they gathered up against the dwelling of a Dr. Laport, at the east end. The fire, however, was soon extinguished by the fire brigade. Revolver shots were freely fired at the police. The opening of the Theatre Royal has been indefinitely postponed on account of the epidemic. At high mass in the Roman Catholic Cathedral, a papal decree was read, which is considered as applying to the small-pox epidemic in Montreal, and which was issued by His Holiness Pope Leo XIII, under the date of the 20th of August last. The decree alludes

to the ravages of epidemics and plagues among the faithful throughout the world last year, and impresses upon Roman Catholics the efficiency of prayer in crushing these regrettable calamities.

We are glad to learn that some of the Roman Catholic clergy are heartily endeavoring to promote proper sanitary measures.

#### MEDICAL NOTES.

—The *Western Druggist* lifts up its voice in lamentation and protest against what it calls the "abominable chirography" of many physicians. It adds: "A physician who cannot or will not write a clear legible hand, should be debarred from practice, or at least be required to have in constant attendance a capable penman. A Department of Penmanship is the crying need of the hour in our medical colleges. There is very little practical difference between bad prescription-writing and downright malpractice."

—The composition of Mrs. Allen's Hair Restorer ("not a dye") is given according to two formulæ in the *Therapeutic Gazette*. Masset gives it thus:

R. Sulphur præcip. . . . .	17 parts.
Poly. cort. Cinnamon . . . . .	2 "
Glycerin. pur. . . . .	320 "
Plumbi Acetat. . . . .	265 "
Aque . . . . .	630 "

According to Wittstein it is:

R. Flor. sulph. lot. . . . .	56 parts.
Plumbi Acetat. . . . .	8 "
Glycerin pur. . . . .	100 "
Aq. arom. . . . .	200 "

—We notice in the columns of a daily contemporary some melancholy instances of the failure of panaceas to cure their own manufacturers. Four or five patent medicine doctors have ended their lives in pain and disease. According to this authority Dr. Pierce of Buffalo is a paralytic; Holmbold, an irresponsible and demented person; the name of Jayne is perpetrated in a line of insane children; Dr. Schenck was for years before his death blind; Ayer, cursed more seriously than either; Warner is a confirmed invalid.

#### PHILADELPHIA.

—The City Council, in order to ascertain the actual degree of contamination of the city water supply, appointed several months ago a Commission, consisting of Prof. J. W. Mallet, of the University of Virginia, Prof. T. G. Wormley, of the University of Pennsylvania, and Prof. Wm. H. Greene, of the Philadelphia High School, to make an examination. Samples of the water taken from different points along the course of the Schuylkill, and from the Delaware (which supplies the northeastern part of the city), gave a very favorable showing. The results in brief were: No traces whatever of poisonous metals, as lead, copper, mercury, or arsenic were found, and no inorganic substance which in itself or in the quantity found could be harmful. The degree of hardness is slight. Organic matter, which is always present in river waters, does not exist in proportion above normal, or such as to make the water unwholesome. It must be remembered, however,

that a less amount than found might become injurious by furnishing the conditions for the development of disease producing germs. Two samples, 3 and 4, were found better than the standard, and three inferior, 1, 5, and 7, ranked in the order named, but none were harmful. Comparing the results with the figures for other large cities, Philadelphia's water is found to occupy a medium position; Chicago and Baltimore water is better, New York (Croton) about the same, and Boston and New Orleans worse. The report continues: "A suggestion of practical value is furnished by the comparison of water from the lower or down stream pumping stations (as for instance, Nos. 5 and 7), on both the Schuylkill and Delaware, with that taken from these rivers higher up. The evidence is very apparent of pollution going on within the limits of municipal authority. The importance of providing for the exclusion from the rivers of sewage and foul drainage water of any kind lies, not merely in the direct consequent reduction in the amount of impurities in the water people drink, but to a much greater extent in reducing the chance of the living germs of noxious organisms finding their way into the water, there to be nourished by and to render dangerous dead organic matter which of itself might be harmless enough. In the event of such an epidemic as one of cholera gaining but a first foothold in some parts of the city, this consideration would at once acquire a degree of importance scarcely to be overestimated." Active measures have been already instituted to correct some of the evils referred to in this report, especially the contamination of the Schuylkill by sewage within the city limits by the mills, hotels, and breweries along its banks. An intercepting sewer is being pushed forward in order to carry away the drainage of some settlements up the river, but it cannot be completed for several years, and will cost millions of dollars. In the meantime, the health of the city has been remarkably good during the summer.

—At a recent meeting of the County Medical Society, Dr. C. K. Mills read a paper entitled "Some Points on the Treatment of Hysteria." He discussed especially the value of operations such as oophorectomy, the management of grave hysterical or hysterio-epileptic attacks, the danger of not recognizing the co-existence of organic disease with hysteria in convulsive and maniacal cases, and the best methods of using "moral" treatment. Ground was taken that oophorectomy should only be performed in rare cases where well-marked objective signs of disease of the ovaries or violent nymphomania were present. Cases were cited. The lecturer held that there was no warrant for the oophorectomy in the case of young girls in whom the menstrual function had not been established.

Hysterio-epileptic attacks were considered as of three classes: (1) the purposive or voluntary; (2) the non-purposive or involuntary; (3) those which were partly purposive and partly involuntary. Great mistakes were made by tyros, in treating cases apparently the same as really the same. Threats, pure moral measures, sometimes heroic procedures, inhalation of ammonia, compression of the nostrils by the Hare method, etc.,

could sometimes be used in the purposive cases with success; but even these required for their successful use, tact and judgment on the part of the physician. Nitrite of amyl by inhalation and strong nerve pressure, he regarded as most valuable in the severer involuntary and partly-involuntary cases. He mentioned instances of anæmia, brain tumor and abscess, and acute mania, treated as purely hysterical, and in which death occurred. He believed that harsh measures should only be employed after much consideration and by a well-planned method.

—At the same meeting, Barrett's new Chloride of Silver Galvanic Battery and a milliamperemeter were exhibited by Dr. Mills and their advantages discussed by him and by the members of the Society. The battery, which is manufactured by John A. Barrett, 13 Park Row, New York, was shown to be the most portable, and at the same time most reliable, medical battery that has yet been invented.

—Students are commencing the fall term at each of the schools, and clinics have again begun at the hospitals, of which there are many. Indeed, in clinical advantages, the schools of Philadelphia are very highly favored.

—A very promising young physician of this city, Dr. F. K. Musser, died with cerebral meningitis last week, after extreme suffering. At the autopsy, a tumor was discovered at the base of the brain, surrounded by considerable congestion. From the fact that morphine had been taken in an ordinary dose to relieve pain shortly before he died, it was thought possible that the drug might have caused death, but the autopsy showed the cause of death to have been that mentioned.

#### CHICAGO.

—The Faculty of Rush Medical College has determined that, after the present college year—which ends next March—it will require, as an additional condition of graduation, a course of practical instruction in the laboratory of physiology and pathology. This course will include the practical use of the microscope, cutting, staining and mounting of specimens, study of the simple tissues of the body and of urinary sediments. This college has for about ten years required a course of practical work in the chemical laboratory.

#### MISCELLANY.

##### HOW SHALL THE PRACTITIONER DISINFECT HIS HANDS.

A THOROUGHLY efficient disinfection of the physician's hands, remarks the *Therapeutic Gazette*, is more than a matter of personal cleanliness; it is an absolutely required, though often neglected, protection of his own person and the safety of his family, friends, and patients. There being no dissenting voice as to the necessity of this by no means irksome precaution, the only question that can arise in this respect is, What method of disinfection insures the greatest success? The present state of bacteriology must convince even the most sceptic and conservative physician that soap and water exercise not the slightest influence

over the microbial organisms, and that the true antiseptic agents have to be resorted to.

Forster, of Amsterdam, made some special researches in this field (*Pharm. Centralblatt*, May 28, 1885) with the view of ascertaining the relative worth of carbolic acid, boric acid, chloride of zinc, and iron. He gained the conviction that the ordinarily used two and one-half per cent solution of carbolic acid, and even Billroth's plan to wash the hands in muriatic acid and ten per cent phenol in glycerine, were insufficient to sterilize the hands, that is, prevent microbial growth on them. The only procedure which Forster found absolutely reliable was the one recently recommended by Koch, of Berlin, which consists in a solution of corrosive sublimate having a strength or seven to fifteen grains to two pints of distilled water. The simplicity of the manœuvre and its unquestionable prophylactic power will go far to recommend Koch's wash to the American practitioner.

#### THE ANTIDOTE TO DATURINE.

The *Medical Times* reports that a Hungarian physician, being called to a child of four who was in a comatose condition from having eaten, as her playfellows said, two handfuls of the ripe berries of the thorn apple (*Datura Stramonium*), and in whose vomit the berries could be plainly detected, gave pilocarpine hypodermically, thinking that as that had proved successful in atropine poisoning it ought to be useful in datura poisoning also. He began with the fourteenth of a grain, and as no effect was produced, he increased the dose to a seventh. As improvement was now evident this was repeated. Altogether in five hours he gave six-sevenths of a grain, and by that time the child was convalescent. No physiological symptoms of pilocarpine were produced until the last dose was given, which was followed by profuse secretion of saliva and perspiration. The author therefore concludes that five-sevenths of a grain of pilocarpine had been required to neutralize the daturine, its own physiological action not coming into play until that was completely effected. He thinks that this case sufficiently demonstrates that pilocarpine is antidotal to daturine.

#### COCAINE IN SEA-SICKNESS.

SEA-SICKNESS is the latest malady to yield to the influence of cocaine, according to a preliminary report on some observations upon "cocainum muriaticum," by Dr. Manassein, of St. Petersburg, (*Berl. Klin. Wochenschr.*, August 31, *Lancet*, September 5). This writer had read of the value of cocaine in uncontrollable vomiting of pregnancy, and thought it might be useful in sea-sickness. He therefore went this summer on a sea voyage in order to test its efficacy. Among his fellow-passengers were two, a man and woman, who were especially prone to the malady. He administered to each of them every two or three hours a teaspoonful of the following solution: Muriate of cocaine (0.15) rectified spirits of wine (in sufficient quantity), and distilled water (150.0), beginning the administration on starting. That it had a prophylactic effect seemed clear, for in spite of very rough weather for a period of forty-eight hours, both the individuals were for the first time in their lives free from sickness, and enjoyed a very good appetite the whole time. To a child six years old, who began to be attacked with sea-sickness

on rising in the morning, the treatment was so effectual that it was able to play about during the day in spite of the storm. The child took one teaspoonful in two doses during the first half-hour, and then half a teaspoonful every three hours. Another case was that of a girl, eighteen years of age, who had been sick for twenty-four hours before the drug was given. The case being a severe one, she had a double dose every half-hour, with "truly magical effect"; for after the second dose the patient was able to assume a half-sitting posture, and after the sixth dose she jested and began to complain of hunger. During the rest of the voyage she remained well, although there was much rolling of the vessel. Similar good results attended the use of the drug in three milder cases; and had it not been that his supply ran short, Dr. Manassein would have been able to make more extended observations. Still, from the experience of these few cases he thinks it justifiable to infer that in the drug we have a certain and harmless remedy against sea-sickness. In the same communication he mentions that he had found "cocainum muriaticum" of great service in arresting the collapse of two severe cases of simple cholera, and thinks it desirable to try its action in cases of Asiatic cholera.

#### EFFECTS OF VERY LOW TEMPERATURES ON LIVING ORGANISMS.

MR. J. J. COLEMAN and Professor M'Kendrick have, as we learn from the *Medical Press and Circular* (September 16), made some remarkable experiments on the effects of low temperatures on living organisms, particularly microbes, using for this purpose the cold-air machinery invented by Mr. Coleman, which, in its ordinary working delivers streams of air cooled to about 80° below zero (= 63° C.), but by certain modifications as low temperatures can be secured as have yet been produced in physical researches. The experiments consisted in exposing for hours to low temperatures putrescible substances in hermetically sealed tins or bottles, or in flasks plugged with cotton-wool. The tins or flasks were then allowed to thaw, and were kept in a warm room, the mean temperature of which was about 80° F. They were then opened and the contents submitted to microscopical examination. The general result may be stated thus: The vitality of micro-organisms cannot be destroyed by prolonged exposure to extreme cold. It is clear, therefore, that any hope of preserving meat by permanently sterilizing it by cold must be abandoned, for the microbes, which are the agents of putrefaction, survive the exposure. Some of the experiments on which this conclusion rests are briefly described. Meat in tins, exposed to 63° C. for six hours underwent (after thawing) putrefaction with generation of gases. Trials with fresh urine showed that freezing at very low temperatures of 63° C. for eight hours did not sterilize the urine. Samples of fresh milk exposed to temperatures of from zero to -80° F. for eight hours curdled, and showed the well-known *Bacterium lactis*; and so far as could be observed, freezing did not delay the process after the flasks were kept at a temperature of 50° F. Similar results were obtained with oil, meat juice, vegetable infusions, etc.

It is probable that the micro-organisms were frozen solid. One cannot suppose that in these circumstances any of the phenomena of life takes place; the mechan-

ism is simply arrested, and vital changes resume their course, when the condition of a suitable temperature is restored. These conditions led the author to examine whether any of the vital phenomena of higher animals might be retained at such low temperatures. They ascertained that a live frog might be frozen through quite solid in about half an hour at a temperature of  $-20^{\circ}$  to  $-30^{\circ}$  F. On thawing slowly, in two instances, the animal completely recovered. After long exposure, the animals did not recover. In two cases frogs were kept in an atmosphere of  $-100^{\circ}$  F. for twenty minutes, and although they did not revive, yet, after thawing out, their muscles still responded feebly to the electrical stimulation. One experiment was performed upon a warm-blooded animal—a rabbit. The cold-blooded frog became as hard as a stone in from ten to twenty minutes, but the rabbit produced

in itself so much heat as enabled it to remain soft and comparatively warm during an hour's exposure to  $-100^{\circ}$  F. Still its production of heat was unequal to make good the loss, and every instant it was losing ground, until, at the end of the hour, its bodily temperature had fallen about  $56^{\circ}$  F. below the normal, but was still  $143^{\circ}$  F. above the surrounding temperature. When taken out the animal was comatose, and reflex action was abolished. Placed in a warm room, its temperature rose rapidly, and the rabbit completely recovered.

It is remarked in this connection that the inability of microbes at low temperatures has been also demonstrated by Pictet and Young, who found that various bacilla can survive  $-70^{\circ}$  C. for 109 hours. After such exposure the Bacillus Anthraxis retained its virulence when injected in a living animal.

REPORTED MORTALITY FOR THE WEEK ENDING SEPTEMBER 19, 1885.

Deaths reported 1,388: under five years of age 785; principal infectious diseases (smallpox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrhoeal diseases) 484, consumption 266, lung diseases 113, diarrhoeal diseases 221, diphtheria and croup 101, typhoid fever 61, malarial fevers 38, whooping-cough 27, cerebro-spinal meningitis 17, scarlet fever seven, puerperal fever six, smallpox two, measles one. From malarial fever, New Orleans 10, Baltimore nine, New York eight, District of Columbia six, Philadelphia and Charleston two each, New Haven one. From whooping-cough, New York 18, Philadelphia three, Baltimore and District of Columbia two each, New Orleans and Providence one each. From cerebro-spinal meningitis, New York six, Philadelphia and Fall River three each. From scarlet fever, District of Columbia, Providence and Fall River two each, Philadelphia one. From puerperal fever New York two, Philadelphia, Bal-

timore, Nashville and Charleston one each. From smallpox, New York and Haverhill one each. From measles, New York one.

Cases reported in Boston: typhoid fever 39, diphtheria 19, scarlet fever 14, and measles three.

In 108 cities and towns of Massachusetts, with an estimated population of 1,387,385, (estimated population of the State 1,955,101), the total death-rate for the week was 17.76 against 18.16 and 17.19 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,946,146, for the week ending September 5th, the death-rate was 18.0. Deaths reported 3,070: infants under one year of age 993, acute diseases of the respiratory organs (London) 139, diarrhoeal diseases 351, measles 74, whooping-cough 62, scarlet fever 49, fever 21, diphtheria 21, smallpox (London) three.

The death-rates ranged from 8.4 in Huddersfield to 25.3 in Cardiff; Birkenhead 20.2; Birmingham 17.8; Bradford 18.0; Leeds 17.5; Leicester 22.2; Liverpool 23.9; London 15.8; Manchester 24.6; Nottingham 17.3; Sheffield 17.8; Sunderland 23.3. In Edinburgh 16.7; Glasgow 24.2; Dublin 22.8.

For the week ending September 5th in the Swiss towns there were 27 deaths from diarrheal diseases, consumption 27, lung

diseases nine, typhoid fever nine, smallpox five, puerperal fever one, measles one, whooping-cough one.

The death-rates were: at Geneva 16.2; Basle 24.2; Berne 20.7; Zurich 11.6.

The meteorological record for week ending September 19th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole of the United States Signal Corps:—

Week ending	Barometer.		Thermometer.		Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM SEPTEMBER 19, 1885, TO SEPTEMBER 25, 1885.

##### PROMOTIONS.

McPARKIN, T. A., lieutenant colonel and assistant medical purveyor. To be surgeon with rank of colonel, to date from September 16, 1885.

IRWIN, B. J. D., major and surgeon. To be assistant medical purveyor, with rank of lieutenant colonel, to date from September 16, 1885.

POPE, B. F., captain and assistant surgeon. To be surgeon with rank of major, to date from September 16, 1885.

##### APPOINTMENT.

MORRIS, EDWARD R., to be assistant surgeon with rank of first lieutenant, to date from September 17, 1885.

AINSWORTH, F. C., captain and assistant surgeon. From Department of Texas to New York City, for duty as recorder of the Army Medical Examining Board. S. O. 214, A. G. O., September 18, 1885.

SHANNON, WM. C., captain and assistant surgeon. Granted leave of absence for four months, to take effect about October 1st. S. O. 215, A. G. O., September 19, 1885.

#### OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING SEPTEMBER 26, 1885.

DENIGAN, J. S., medical director. Waiting orders.

##### OBITUARY.

William Augustus Guy, M.B. Cantab, F.R.C.P., F.R.S. The death of this writer who was in the front rank of statisticians and philanthropists, occurred at his residence, Gordon Square, London, on the 10th instant, in his seventy-sixth year. Dr. Guy was born of a line of medical ancestors at Chichester in 1810. He received his early education at Christ's Hospital, passed through his medical curriculum at Guy's Hospital, and took his M.B. degree at Cambridge, in 1837. In 1834 the Medical Society awarded him the Fothergill Medal for an essay on asthma. Appointed in 1838, he filled the Chair of Forensic Medicine in King's College for many years; in 1842 he was attached to the Hospital in charge of outpatients; from 1845 to 1848 he was Dean of the Medical Department, and in 1863 became Professor of Hygiene. He was admitted a Fellow of the College of Physicians at the age of thirty-four, and repeatedly held the offices of Lecturer, Examiner, and Censor in that institution. He was an active worker in the Statistical Society, and, in addition to numerous contributions to its Journal, filled the offices of Honorary Secretary, of Vice-President, and of President. In 1860 the Swiney Prize was awarded him for his researches in Forensic Medicine. In 1876 he was a Vice-President of the Royal Society.

##### CORRECTION.

In the report of an accidental puncture of a distended pericardium, JOURNAL, September 17th, page 276, it should have been stated that the needle was inserted in the *axillary*, not the "mamillary," line.

##### SOCIETY NOTICES.

BOSTON SOCIETY FOR MEDICAL OBSERVATION. — A regular meeting of the Society will be held at the Medical Library, 19 Boylston Place, on Monday, October 5th, at 8 P. M. Readers: Dr. T. A. De Bois, "The Rapid Fatality of Tuberculosis Involving the Pharynx." Dr. J. P. Ayer, "Cases of Glycosuria." H. L. BURRELL, Secretary.

NEW YORK STATE MEDICAL ASSOCIATION, FIFTH DISTRICT BRANCH, BROOKLYN. — The first annual meeting of the Fifth District Branch will be held in Brooklyn, at the Mansion House, Hicks Street, between Clark and Pierpont Streets, at 11 A. M., on Tuesday, October 13, 1885. Order of business: Reading of the minutes, appointment of nominating committee, report of the executive committee, reports of delegates to other branches, scientific business: "Suggestions in regard to the Causation and Treatment of Acute Coryza," by Anstin Flint, M.D., "Further Observations on Diphtheria," by W. H. Thayer, M.D. Adjournment at 1 P. M. for lunch. Meeting called to order at 2 P. M. Scientific business continued: "The Physician and the Pharmacist: Their relative Duties," by J. P. Garrish, M.D. Report of a "Case of a Railroad Accident," by Wm. Goran, M.D. Remarks on "The Milk Supply of large Cities and the Improper Mode in which it is conducted," by H. A. Pooler, M.D. "Progress of Electrolysis in Surgery," by Robt. Newman, M.D. New business, report of nominating committee, adjournment. This being the annual meeting, a full attendance is especially desired. Lunch can be obtained in the Mansion House on reasonable terms.

J. C. HUTCHINSON, M.D., President.

E. H. SQUIER, M.D., Secretary.

NOTE. — The Mansion House is only a short walk from either Fulton Ferry, Wall Street Ferry, or the Bridge terminus in Brooklyn. Fellows should walk straight up from either Ferry until they reach Hicks Street.

##### BOOKS AND PAMPHLETS RECEIVED.

Tabular Statistics of One Hundred Cases of Urethral Stricture Treated by Electrolysis without Relapse. By Robert Newman, M.D., of New York. (Reprinted from New England Medical Monthly.) 1885.

A Treatise on Nervous Diseases: Their Symptoms and Treatment. A Text-Book for Students and Practitioners. By Samuel G. Webber, M.D. New York: D. Appleton & Co. 1885.

A System of Obstetric Medicine and Surgery Theoretical and Clinical for the Student and Practitioner. By Robert Barnes, M.D., and Faneur Barnes, M.D. Illustrated with 281 woodcuts. Philadelphia: Lea Brothers & Co. 1885.

A Text-Book of Medical Chemistry for Medical and Pharmaceutical Students and Practitioners. By Elisha H. Bartley, M.D., Adjunct Professor of Chemistry and Lecturer on Diseases of Children in Long Island College Hospital. With Forty Illustrations. Philadelphia: P. Blakiston, Son & Co. 1885.

ANÆSTHETICS IN NORMAL LABOR.<sup>1</sup>

BY R. A. KINGMAN, M.D., OF BOSTON.

UPON scarcely any subject in the department of obstetrics does there exist greater difference of opinion than upon the advisability of mitigating the pain of normal labor by the employment of the anæsthetic agents at our disposal. Not only is this true of the great authorities in obstetrical literature, but it is equally true of the physicians in our own city, and even of the instructors in the medical school; and this fact has seemed to me to offer a sufficient apology for calling your attention to the subject this evening. It is not my intention to formulate precise directions as to how, when and what anæsthetics should be used, though incidentally each of these points shall receive brief attention. I do expect, however, to be able to give some strong arguments in favor of the practice I am advocating, to disprove some, if not all, of the arguments of the opposition, and finally to reach the logical conclusion that, having at our disposal substances capable of safely and effectively relieving pain without materially affecting the progress of labor, it becomes our duty as physicians to, at least, offer to our parturient patients, a mitigation of their sufferings.

The drugs which are of the greatest practical importance to us in this connection are chloral and ether, and to these alone our attention shall be confined. I make no apology for omitting chloroform from the list, for I am aware of no good reason for using one anæsthetic in surgery and another in midwifery, and as to the superiority of ether in the former field there can be no question. Nor is it necessary to even mention the many other drugs that during the past few years have been classified with those already mentioned. Chloral and ether will serve every purpose, and being freer from objections than the others, may be taken under consideration as types of the class.

Chloral, though discovered as early as 1832 by Liebig, was not employed in medicine till the year 1869, when Liebreich began experimenting with it. Noting the fact that in the presence of alkalies, chloroform was produced, he reasoned that this same transformation must occur in the blood, and that consequently chloral was capable of inducing true anæsthesia. The effect of this hypothesis was to bring the drug into immediate popularity. It was made use of in almost every conceivable ailment, in obstetrics as well as in general medicine. Failing to answer all expectations, however irrational, it rapidly fell into disrepute, from which it has never fully recovered.

That we may the more intelligently assign it the place that it is undoubtedly fitted to fill in the field of obstetrics, let us study for a few moments its action upon the uterine contractions, the extent of its anæsthetic and hypnotic powers, and its influence, if any, upon the health of the mother and the child. The facts that I am about to state are derived largely from the valuable monograph<sup>2</sup> of A. Pellissier, of Paris, published in 1873, in which is given, not only the result of his own deliberations and ordinary clinical experience, but of a careful and very conclusive series of experiments upon animals. He formulates three propo-

sitions which cover the whole matter so perfectly that I will give an almost literal translation. They are as follows:

"1st. Chloral does not in the least suspend the progress of the labor.

"2d. It causes a diminution of pain, sometimes even its almost complete suppression, and procures to the patient a calm and refreshing (*réparateur*) sleep, the result of which cannot be otherwise than favorable to her.

"3d. Employed in a wise and prudent manner, it is absolutely innocuous."

In proof of the first proposition can be arrayed the declarations of such men as Pajot and Simpson, who state that the contractions of the uterus continue regularly and powerfully, and that they have never seen them suspended in consequence of the administration of chloral; or the still stronger declaration of Lambert of Edinburgh, to the effect that "far from suspending the uterine contractions, chloral renders them still more active," and that "the labor, under the influence of chloral, will probably be of shorter duration, for the reason that unconscious contractions are more powerful than painful ones."

These and many other similar statements may be adduced to show that the action of the uterus is not interfered with by the drug under consideration, but that the fact may not appear to rest upon simple assertion, witness the following experiments as related by Pellissier.

Not being able to procure pregnant bitches, he operated upon unimpregnated ones, exciting the uterus to contract by touching it with an electrode. In one case he injected into the intestine two doses of chloral of two grms. each. After the first dose the dog slept profoundly, though reflex movements were unaffected. After the second dose complete anæsthesia supervened. In this connection the uterus was seen to contract vigorously, though the duration of the contraction was slightly less than before the chloral was administered. The contractibility was not at all affected by the first dose. The dog rapidly recovered from the effects of the chloral and from the operation.

It was found that when ludanum was employed instead of chloral, the uterine contractions were almost entirely annulled.

If now it be remembered that we never have occasion to give chloral to anything like the extent here mentioned, it is obvious that the tendency of the uterine fibres to contract under stimulus must be very little, if at all, interfered with.

As my own experience with chloral has been entirely in accord with the facts just stated, I may perhaps be permitted to report very briefly a single case, which may serve as an illustration of the actual results to be expected. In this particular case, the total amount of chloral given was five grms. distributed through several hours of the evening. The patient was a primipara who had suffered acutely from a prolonged and very painful first stage. The primary effects of the drug were to produce sound and refreshing sleep with almost complete extinction of pain, the patient waking and complaining slightly of each contraction. For about an hour she slept continuously, taking no notice of the pains which continued without interruption. At no time did I notice any diminution, either in the force, duration, or frequency of the contractions. The effect of the chloral was marked until the latter part of the

<sup>1</sup> Read before the Section for Obstetrics and Gynecology, of the Santé District Medical Society, May 29, 1885.

<sup>2</sup> Des Indications de l'Hydrate de chloral dans l'Accouchement.

second stage, when it was supplemented by the inhalation of ether.

Much larger doses than those employed by myself have been frequently given by French accoucheurs, the amount sometimes reaching twelve or even twenty grms. in the course of a few hours, and yet the testimony of these men is that chloral never interferes with the progress of labor except in those cases in which the duration is actually diminished by it.

The second proposition states a fact of such universal experience that it seems almost superfluous to attempt its proof, and yet, as it is a fact of vital importance to the object of this paper and that nothing may appear to be taken for granted, a few brief statements may be made in its support. By it, anæsthetic and hypnotic powers are claimed for chloral. Let us see how far these claims can be substantiated.

Pellissier, as a result of his experiments, presents sphygmographic tracings which, beyond a question, demonstrate the production of complete anæsthesia in dogs. If thus affective with dogs, it is safe to assert that it is capable of producing the same result in human beings, the only reason why it is not so used being the fact that in pushing the drug to such an extreme, the safety limit might easily be over-stepped. Though for this reason it is not advisable to attempt the production of surgical anæsthesia, there seems to be no ground for denying that lesser degrees of the same condition, may, and frequently do occur as a result of ordinary therapeutic doses. By virtue of this anæsthetic property of chloral, the pains of labor may be sufficiently overcome to afford free play for the drug in a calmative and hypnotic direction. The excitement of the patient being quieted, the pain being lulled, and the sense of continual discomfort and apprehension being obliterated, exhausted Nature asserts herself and the patient sleeps. According to the amount of the drug exhibited the sleep will be deep or light, quiet or uneasy, the pains will be unnoticed or will give rise to lively manifestations of suffering. This sleep being in many respects a natural one and the patient being in the midst of an exhausting process, may I not be permitted to assert without further demonstration that it "cannot be otherwise than favorable to her?" It must refresh her, strengthen her, favorably influence the progress of labor and insure a more comfortable and certain convalescence.

"Employed in a wise and prudent manner, it is absolutely innocuous."—this is the language of the third proposition, and in attempting its support, I would not strive to conceal the fact that a very considerable number of deaths have arisen from the administration of the drug. I do venture to assert, however, that in almost every case of fatal, or even alarming chloral poisoning, the saving clauses in the above statements have been disregarded, that is, the drug has been given in an unwise or imprudent manner. Either the initial dose was too large, the repeated doses too heavy or given at too short intervals, thus producing a cumulative effect, or some of the contraindications have been overlooked. Deaths have occurred from very moderate doses of opium, yet is that fact advanced as a reason why an opiate should never be given simply to relieve suffering? As we are dealing, in this paper, merely with the effects of chloral administered during the course of labor, the question becomes much simplified, for, so far as I have been able to learn, not a single case of fatal poisoning has ever occurred from such use

of the drug. That the chronic use of chloral may, and often does entail a series of characteristic symptoms, is neither denied nor doubted, but that so brief an employment of it as I am advocating is ever followed by unpleasant results few have claimed and none have ever proved. On the contrary, it is universally admitted that the great superiority of chloral as a hypnotic lies in the fact that it is not followed by headache, mental or physical depression, dyspepsia or constipation, but that it leaves the patient in the normal condition of one who has enjoyed a perfectly sound and natural sleep.

It having already been demonstrated that the uterine contractility is unaffected by chloral, it follows as a corollary that post-partum hæmorrhage cannot be caused by it, as claimed by some. It is an undisputed fact that chloral administered to the mother during labor has no injurious effect whatever upon the child.

There is one important action of the drug under consideration which, though not referred to in either of the three propositions, is worthy of mention here. It possesses in a marked degree the power of relaxing the spasmodic contractions of the circular fibres of the cervix. In those cases of unyielding os, in which the rigidity is due to the above cause and is not complicated with cicatricial or inflammatory hardening of the tissues, we may expect a speedy relaxation under the use of chloral.

Concerning the administration of chloral, no minute directions need be given. I do not recommend it for every case of labor; but I do consider that in cases in which the pains are acute, continuous, exhausting or ineffective, in which the patient is nervous, excited, apprehensive or depressed and discouraged, or in which the os is spasmodically resisting the forces that tend to dilate it, in all such cases, I say, chloral is indicated. For the multipara, whose labor of an hour or two is almost devoid of pain, and in whose case loss of sleep is not an incident, no chloral is necessary; but what reason can be advanced for refusing it to the primipara, harassed by nagging and ineffective pains, to whom sleep has been a stranger for hours, and it may be days, who is certain yet to have at least some hours of similar or even worse suffering, and to be left, when it is all over, exhausted, prostrated, in such a condition as to render hæmorrhage liable, puerperal disease more probable, and convalescence tardy? In such extreme cases and in the more common simpler ones, let chloral be given to such an extent as to relieve suffering, quiet agitation, and afford sound refreshing sleep.

I would suggest that either one or two grammes be given at once, according to the exigencies of the case, to be followed by one gramme doses at intervals of one half to one hour until the desired effect be produced. After that, give only as required to continue the effect.

Coming now to the subject of ether, there are certain questions that must be answered before we can decide upon the merits of the case. What is its effect upon the uterine contractions? What upon the dilatation of the os? What upon the distensibility of the perineum and upon the chances of its rupture? What upon the aid afforded by the abdominal muscles? What is its value as a calmative, hypnotic and anæsthetic agent? What are its subsequent effects upon mother and child? How great is the danger attending its use?

First. What effect has ether upon the uterine con-

tractions? This is the question that has occasioned more difference of opinion than any of the others, and upon it, more than upon any other, hinges the rule of practise. Many of the best authorities claim, and with perfect candor, that the inhalation of ether causes diminution, both in force and frequency, of the contractions of the uterus, and that, both as a result of this fact and in consequence of its depressing influence upon the vital forces, it predisposes to hemorrhage. On the other hand, quite as good and as abundant authority can be offered for the contrary statement that ether, given for the purpose and according to the method to be advocated later, does not delay the labor, that it occasionally even increases the force of the contractions, and that statistics do not show any increase in the percentage of post-partum hemorrhages following its use.

Now to affirm that both of these statements are literally true would be to assert an apparent paradox, yet that such is the case can readily be shown. The whole difficulty lies in the fact that the first class of observers overlook the saving clause in the second statement, namely, "for the purpose and according to the method."

As will be seen subsequently, the meaning of this is, that in giving ether during labor simply for its anæsthetic and hypnotic effects, the degree of surgical anæsthesia should never be reached. It is never necessary to give it even to the abolition of complete consciousness. This fact, I say, is overlooked by the first class of observers, who take into consideration as well those cases in which ether is given to the total extinction of consciousness, to the production of surgical anæsthesia and even all the cases of operative midwifery in which no one can estimate the influence of the operation itself or of the cause that made operation necessary.

Before going further it is necessary to state that most of the authorities to be referred to, are discussing chloroform, but it will readily be admitted that what can be said in favor of the more powerful agent, at least in this connection, is doubly true of the weaker and safer. It is necessary to make use of the testimony concerning chloroform because so comparatively little has been written on the subject of ether for reasons that are sufficiently understood.

Prominent among the advocates of chloroform stands Professor Barker<sup>2</sup> of New York, who is authority for the statement that chloroform sometimes lengthens the labor, but in a large majority of cases it shortens it. He classifies these latter cases under three heads:—

- (1). Those in which inefficient uterine action results from loss of sleep and exhaustion from prolonged first stage.
- (2). Those in which delay occurs from rigidity of the os or perineum. (The rigidity being due of course to muscular action and not to fibrous contraction.)
- (3). Those in which pains are inefficient from hysteria, vivid moral impressions, or severe pain due to other causes than uterine contractions, as, for instance, some pre-existing disease.

Concerning post-partum hemorrhage, he says it is usually due to uterine inertia which is commonly the effect of exhaustion. This condition does not obtain where ether is used, and consequently hemorrhages ought to be less frequent.

A single case reported by the same author may serve

to illustrate the occasional action of chloroform in increasing deficient uterine action, and the same property may be quite as strongly claimed for ether. A primipara having had a first stage of eighteen hours, entered upon the second stage with strong and efficacious contractions, but after five hours these became irregular and feeble, finally ceasing altogether. Preparatory to the application of forceps, chloroform was administered, the patient coming rapidly under its influence. Immediately the pains started up and in twenty minutes the child was born naturally. Dr. Barker says that since that time he has often witnessed the same results.

Dr. Piachaud, of Geneva, in a thesis<sup>4</sup> presented before the International Congress of Medical Sciences in 1877, says that by the use of chloroform he was enabled to leave many cases to the efforts of nature which otherwise he must have terminated with forceps.

The second question needs no discussion, for the effect of ether upon the os is almost identical with that of chloral. So with the third question, concerning the perineum, except that here enters another item for consideration. It is claimed that the patient having her sense of pain benumbed and having to a certain extent lost her power of self-control, will strain down just at the critical moment and thus determine a rupture which might otherwise have been prevented. So much truth is there in this statement that I would advise that, at the moment when the head is passing the vulva, the ether should be so far suspended as to insure the entire co-operation of the patient. If this caution be borne in mind the result will be a less number of ruptures than when ether is not given, for the reason that the patient being better able to bear the pressure of the head in the outlet, its expulsion can be permitted to take place more slowly. In those cases in which the pains are exceptionally severe, or in which the patient has shown herself nardy, it will be better to push the ether to the production of surgical anæsthesia.

It has been noticed and commented upon as a curious fact that the abdominal muscles continued to play their part in the process of labor, even though the other voluntary muscles of the body were completely relaxed by the use of an anæsthetic, and it is only within recent years that it has been explained on the ground that these muscles belong to the respiratory system, and therefore are among the last to lose their activity. As, however, the patient need not be placed so deeply under the influence of the anæsthetic as to lose her consciousness, she will continue to assist the process by voluntary efforts which are often much stronger and more prolonged than when the ether is withheld.

The fifth question that I have propounded is: What is the value of ether as a calmative, hypnotic, and anæsthetic agent?

Its effect is in many respects similar to chloral. Acting much more rapidly and the effect being correspondingly evanescent, yet the patient is soothed, relieved of her suffering to a very considerable degree and is enabled to sleep quietly between the pains. Its effect is immediate, constant and salutary. Being withdrawn, the patient quickly experiences renewed pain and begs for its continuance.

Given as recommended, consciousness is never lost, questions can be asked and answered and directions understood and followed.

<sup>2</sup>Anæsthetics in Midwifery, New York, 1861.

<sup>4</sup>Emploi des Anesthésiques pendant l'Accouchement Naturel.

The subsequent effects upon the mother cannot be such as to play any important rôle in her convalescence, for not being given to complete anaesthesia, its influence must be less than after even a slight surgical operation. By virtue of the rest and relief from pain afforded during labor it ought assuredly to predispose to a more favorable convalescence, just as has been claimed for chloral.

Concerning the child, I am unable to find any report of injury due either to ether or chloroform, and therefore, although much time and space have been occupied in the attempt to determine whether the latter drug, as such, passes into the body of the child, I do not consider any discussion of the subject necessary.

With regard to the danger involved in the use of ether, the simple fact that in the nearly forty years and among the hundreds of thousands of midwifery cases in which ether has been used, not a single death has been attributable to it, would seem to be a sufficient reply to the question. Even chloroform, which counts its victims by hundreds in other than parturient cases, loses here its danger, as a careful search has revealed no more than seven cases in which it proved fatal during labor. And yet see what Professor Depaul, of Paris, gives as his reasons for refusing anaesthetics to his patients:—

“(1) Because the employment of anaesthetics, in spite of what has been said to the contrary, is not always without danger and may kill the woman.

“(2) Because the anaesthetic sleep, in depriving her of her reason, does not permit her, in the great act which she is accomplishing, the participation which is almost always necessary.

“(3) Because the danger and the inconvenience mentioned are not compensated for by the advantages which result from the diminution or the cessation of pain.”

Now I submit that this reasoning is most sophistical. In the first place the danger is less than that attending a carriage or railway ride. True, it may “kill a woman,” but if it never has we are not to be frightened by any such absurd possibility.

Secondly, as advocated for the simple purpose of relieving the pains of labor, it is not necessary nor is it desired to deprive the patient of her reason.

Thirdly, the trifling danger, and quite as trifling inconvenience are vastly more than compensated for by the relief afforded. In other words, Professor Depaul must have been blinded by prejudice or something worse, when he wrote those words, and, in his high position, affording example and teaching to so many students of medicine, he has much to answer for as the cause of untold suffering that might safely and easily have been alleviated.

It is unnecessary to enter into any explanation of the singular immunity from accident during etherization exhibited by parturient patients. Many cases have been assigned, each of which undoubtedly is of value, though to my mind the most important safeguard lies in the method of administration. This method, which is probably familiar to you all and to which reference has already been made, consists simply in the intermittent inhalation of the anaesthetic. As the pain is felt approaching, the patient calls for the ether and takes several strong, deep breaths. As the contraction passes off she falls at once into a sleep from which she only awakes at the advent of a fresh

pain. As has been stated, we wish to abolish neither consciousness nor sensation, only pain. The patient is aware of the contraction but does not suffer from it. She should be able to answer questions and carry out our directions intelligently. To this degree of anaesthesia Piachaud has given the name of *hypæsthesia*.

I would advise that in those cases in which an anaesthetic is indicated, chloral should be given if we have reason to think that the labor will continue more than an hour or two, especially if it still be in the first stage. Where prompt and not very prolonged effect is desired, ether is indicated, as also in those cases in which, after a thorough trial, chloral has failed to give satisfactory results.

I believe that I am now in a position to announce the conclusion proposed at the beginning of this paper that, “having at our disposal substances capable of safely and effectively relieving pain without materially affecting the progress of labor, it becomes our duty as physicians, to at least offer to our parturient patients a mitigation of their sufferings.”

Having thus arrived at a conclusion favorable to the use of anaesthetics in normal labor, this paper cannot better be brought to a close than by quoting Professor Barker's rule of practise and statement of results, as contained in a private letter to Piachaud. He says: “I employ chloroform in all cases except those very exceptional ones in which the pains are not sufficiently violent to cause its request. I have never, in any circumstance, had the least reason to regret having made use of it.”

#### DOUBLE OPTIC NEURITIS AND OPHTHALMO- PLEGIA FROM LEAD-POISONING; COM- PLICATED BY TYPHOID FEVER.<sup>1</sup>

BY O. F. WADSWORTH, M.D.

IN patients suffering from lead-poisoning optic neuritis is not very uncommon, although usually in such cases associated with nephritis. That lead may cause combined paralysis of the extraocular muscles together with neuritis, as in the case I have to report, has not, to my knowledge, hitherto been observed. In the present instance there was not only no nephritis, but aside from the ocular symptoms none which could with probability be referred to lead, at least, which could not as well or better be attributed to the intercurrent typhoid fever.

A well-grown boy of nine years passed the summer of 1881 in the country. In August, twice, at an interval of a week, after riding an easy-gaited horse three or four miles, he complained of headache. Very shortly afterward, at the end of August, he came down with what the physician in attendance called slow fever. He was perhaps a week in bed, complaining of headache, then somewhat better, up and dressed, and with fair appetite. During this time, it was observed that his left eye did not move as well as the other, and about the beginning of his sickness, and occasionally afterward, the left pupil was said to have been somewhat the larger.

As he continued ailing, he was brought to Boston Sept. 25th, and placed under the care of Dr. O. W. Doe, to whom I am indebted for the use of his notes. After reaching Boston, the boy appeared generally rather dull, would sometimes lie quiet for a long time with his face in the pillow, but on one or two days was

<sup>1</sup> Read before the American Ophthalmological Society, July 11, 1885.

quite bright and lively. He had a fair appetite; pulse and temperature were not far from normal; there was no headache; the spleen was decidedly enlarged; there was no other typhoid symptom. The urine contained neither albumen nor casts. Once or twice, while driving in an easy carriage over a smooth road, he complained that the road was rough. The left eye turned neither to right nor left, but could move upward and downward. Electricity was applied to the recti muscles. On October 6th, shortly after eating a good breakfast, he had sudden vomiting with little or no nausea. On the same day, Dr. Doe first observed that the left pupil was a little larger than the right.

I saw him first on October 8th. He was up and dressed, in very good flesh. There was no movement of the left eye inward or outward, somewhat diminished movement downward, good movement upward. The movement of the right eye was decidedly diminished outward, good in other directions. The left pupil was larger than the right; both reacted to light, the right better. Vision R. diminished; L. much diminished; (It may be said here that the determination of the vision was at no time, either now or subsequently, so exact as could have been wished, because of the desire of the boy's mother that nothing should be done to discourage his feeling that his sight was better than it really was.) The media were clear. In both eyes the discs were much swollen, with steep sides, opaque, vascular, the inflammatory appearances confined within an area of not more than two diameters. There were no hemorrhages; the retina was everywhere quite clear and transparent, and its vessels not apparently altered in calibre or course. While many of the symptoms appeared to point to obscure typhoid, I regarded the neuritis and peculiar ocular paralyses as most readily explained on the supposition of a tumor in the region of the pons, and gave that as the probable diagnosis. Potass. lod. gr. x 3 t.d. ordered.

Dr. C. F. Polson saw the patient on the following day, and because of the slight evidences of pressure (headache, vomiting, etc.), and the fact that he had observed anomalous nervous symptoms from lead poisoning, suggested the possibility that that might be the cause of the ocular symptoms here.

On the 10th, the boy took a short drive, complained on his return of weakness, and had dizziness and nausea on moving his head or rising. For the next week or ten days he was confined to bed or sofa, his pulse and temperature high (102.1° was the highest temperature reached), his dejections yellow and typhoidal in character; in short, there were fairly marked typhoid symptoms. He vomited once or twice only after taking his medicine. On the 11th, the spleen reached an inch below the ribs, and there was also increased, hepatic dullness noticed for the first time. For two or three days, the spleen and liver continued to enlarge, but by the 17th had begun to diminish again. On the 21st, the spleen had become of normal size, while the liver still reached two-thirds of an inch below the ribs. A few days later, the liver also had returned to normal dimensions.

Meantime I had seen him twice. On the 14th, vision seemed less in each eye than on the 8th; with the right, the better, eye, he read letters about equal to 30 or 40 at 1'. The field seemed of normal extent in both. Left pupil the larger, both reacted. The swelling of discs a little increased with many fine vessels. The retina bright and clear everywhere. Movements of left as before, perhaps slightly impaired upward also;

movements of right diminished outward, a little diminished inward, and perhaps downward.

On the 20th, the left pupil reacted little by itself, the right well. The right, better, eye, could not count fingers at 16". The fundus as before. Lateral movement of left none, movement upward and downward somewhat defective; movement of right as on 14th.

Before this date, Oct. 20th, an examination of urine passed four days after beginning to take the iodide, had been made by Dr. E. S. Wood, and no lead found. A second examination before Nov. 1st, gave a trace of lead and decided the diagnosis.

Nov. 1st, the temperature was still above normal, the pulse ranging from 100 to 110. The boy was cheerful and improving in general condition. Both pupils were large and equal when I saw him; both reacted promptly to light in the right, or to attempts at accommodation, although never very small. The left eye barely saw movements of the hand; the right counted fingers imperfectly at 1' and with fixation much above. Field of right apparently normal in extent, swelling and vascularity of discs a little less, the rest of fundus clear as before. Movements of left much as on Oct. 20th; of right, inward and outward a little less than before, upward and downward good. He was now taking Potass. lod. gr. xv, and the dose was increased to gr. xx. From this time his general condition steadily improved; by Nov. 7th he began to drive out.

Of a specimen of urine sent on Nov. 10th, Dr. Wood wrote, "there was a larger amount of lead than in the previous specimen; I should designate it as considerable." I did not see the boy again till Dec. 30th. His general health had become very good. His vision had sunk since my last visit, but was thought by his mother and himself to have improved somewhat of late. The movements of the eyes had become quite normal, and the irides reacted well, although the pupils were rather large. There was a little divergence of the left eye, and slight drooping of upper lids of both. It was doubtful if he could count fingers even at a few inches. The right eye was the better, and the best vision was obtained with fixation above and to the right. Swelling of discs nearly gone, their surface pale and showing but few fine vessels, the arteries small, veins nearly normal in size.

He was last seen by me May 9th. He could not count fingers. The outlines of the discs were more defined and their surface more uniform and opaque. His general health was very good. There was then still a trace of lead in the urine, but by the last of May it could no longer be found.

#### A RARE MALFORMATION OF THE HEART.

BY GEORGE F. BRIDGES, M.D.

THE following case of congenital malformation of the heart, which recently came under my observation, furnishes an example of a condition, interesting on account of its rarity.

On July 20th, at the Columbia lying-in hospital in Washington, a healthy colored woman was delivered of a male child. At the time of birth, the child was cyanosed, and it was only after the employment of artificial respiration and various other stimulating measures, that respiration was established. The child lived fifty-four hours, during which time, embarrassment of respiration, rapidity of pulse and great restlessness

were constantly observed. The efforts at nursing were feeble and without result.

At the autopsy, the heart alone was removed and preserved for subsequent examination. The lungs and abdominal organs were examined *in situ*: the former were well aerated, and the latter presented nothing abnormal. Upon later investigation the heart was found to consist of three cavities, two auricles and one ventricle. The auricles were well formed but of unequal size, the left being considerably enlarged. The septum was present and exhibited nothing abnormal except the large size of the foramen ovale, which admitted the tip of the little finger. There was but one, the left, auriculo-ventricular opening. In place of the tricuspid valve, there was a slight depression, at the bottom of which was a minute fibrous ring, 3 mm. in diameter. This was impervious, and an opening made through it, in search of a rudimentary right ventricle, revealed nothing but the dense muscular tissue of the ventricular wall.

The ventricular portion of the heart did not differ in size and external appearance, from normal specimens of the same age. The walls were somewhat hypertrophied, measuring 9 mm. in thickness. Its cavity was spacious, and presented no trace of a septum: from it was given off one large arterial trunk, the aorta. A small vessel, blindly originating at the junction of the anterior wall of the aorta with the ventricle, measuring 3 mm. in diameter, bifurcating 8 mm. above its origin, was observed, and considered by Dr. D. S. Lamb of the Army Medical Museum, to be the rudimentary pulmonary artery. As the autopsy was necessarily hurried, further investigation, with a view to ascertaining the origin of the vessels supplying the lungs, was not undertaken.

Examples of trilobular hearts are by no means common. Peacock, in 1858, had collected but eleven, and the American and British journals, published since that time, furnish an additional record of seven cases. Most of these, however, are examples of an arrest of development taking place at a period of fetal life, much later than the case which is now under consideration. Evidence of this is to be found in the fact, that in nearly every instance, a rudimentary ventricular septum is present, and the pulmonary artery, in a more or less complete state of development, can generally be found to communicate with the ventricle.

Of the few cases which closely resemble this one, can be mentioned the one reported by C. Bernhard, in which there was entire absence of auricular septum, right ventricle, and pulmonary artery; two cases (reported by Owen and Vernon) in which there was absence of left ventricle and aorta, the auricular septum being defective; and the case described by Dr. Heinemann in the *Medical Record* of 1878, which consisted of two auricles and one, the left, ventricle. The aorta being well formed and the pulmonary artery rudimentary and impervious.

Although the specimen exhibits three distinct cavities, considered from a physiological point of view, it should be classed as a bilobular heart, inasmuch as the right auricle, having no connection with the ventricle, serves only as a common venous trunk.

The question of causation in these malformations, is always one of interest. The theory usually accepted is, that defects in the septa are generally secondary, and result from a more or less complete stenosis of some valve or vessel; that this, in nearly every instance,

is present on the right side of the heart, and may be the result of irregular development or an inflammatory process.

Although it is not my purpose to enter upon a discussion of this branch of the subject, it may be added, that the small fibrous ring which was observed in place of the tricuspid valve, probably represents a stenosis of that orifice, occurring at a very early period of fetal life.

## Reports of Societies.

### AMERICAN GYNÆCOLOGICAL SOCIETY.<sup>1</sup>

WEDNESDAY. — SECOND DAY. — MORNING SESSION.

The President, Dr. WM. A. HOWARD, of Baltimore, read the annual address. It was entitled,

#### TWO RARE CASES IN ABDOMINAL SURGERY.

The speaker held that all cases whether successful or not should be put on record, in order that the knowledge of such affections might be increased. The paper described two rare cases of exceptional interest, in which the writer was completely baffled in the diagnosis and declined to make one.

CASE I. S. H., negress, aged twenty-four years, married, presented herself at the dispensary of the University of Maryland, April 20, 1882. She was seen by the clinical assistant and the following notes made. Menstruation appeared at the age of fourteen and had been regular and normal. She was the mother of five children, the youngest of which was two months old. She had never had a miscarriage. Some days after delivery she noticed an enlargement in the lower portion of the abdomen which gradually extended in the middle line until it reached the umbilicus and was attended with bearing-down pains and frequent micturition. On examination, fluctuation was well marked all over the abdomen, with decided resonance about the umbilicus. There was dullness on percussion and bulging in both flanks. Six weeks later she returned to the dispensary and at this time, the resonance at the umbilicus had disappeared and the umbilicus at this time projected. I saw her for the first time two weeks after this observation was made. At this time she was quite sick, the temperature being 102°, the pulse 132 and the respiration 32 per minute. Examination showed the presence of fluid in the pleural sac. There were also some crackling rales heard through the lung. The abdomen was as large as at seven months' pregnancy and was remarkably protuberant in the center. There was complete dullness over the entire abdomen not changed by change of position. There was no evidence of a solid tumor, but it had every appearance of a simple multilocular cyst. Vaginal examination showed the uterus well in front of the tumor and the sound gave a measurement of two and three-fourth inches.

The question which arose was as to the nature of this tumor. Was it ovarian? The extreme infrequency of ovarian tumors in the negro race was against this view. The rapid growth of the tumor was also opposed to this view. The next affection considered was fibro-cystic tumor of the uterus. This is exceedingly rare, the speaker had seen but one such case in the negro. In that case the cyst was filled with pus. The patient was operated upon with a fatal result.

<sup>1</sup> Continued from page 330.

Such tumors are rare before the age of thirty-five; they usually develop slowly. There was no menstrual disturbance in this case. For these reasons, fibro-cystic tumor was excluded.

Was it a parovarian cyst? These usually develop even more slowly than ovarian cysts. They are usually flaccid. They contain a thin liquid, are comparatively rare, and do not affect the general health. This was therefore excluded.

It was certainly not a case of simple ascites, but was it a case of encysted dropsy, so called, of the peritoneum resulting from simple peritonitis? This is an extremely rare affection, and in the early stages there are symptoms of constitutional disturbance, the abdomen is not prominent and often is flaccid. Encysted dropsy was excluded.

Finally, on June 20th, I aspirated the cyst under antiseptic precautions. The fluid which escaped was of a light straw color and coagulated as speedily as blood. After aspiration large masses were readily felt through the abdominal wall. The character of the fluid corresponded with that which is said to characterize fibro-cystic tumors of the uterus. The speaker had, however, seen other cases which showed that the character of the fluid was not pathognomonic. In one case of abdominal tumor, fluid was removed which did not coagulate, even after being kept for many days. The abdomen was subsequently opened and a fibro-cystic tumor found. In a case of supposed ascites in a man, aspiration was performed and the fluid removed coagulated quite rapidly.

After the cyst was aspirated the patient died well for three days, when acute peritonitis supervened and the patient died on the seventh day.

At the autopsy, a mass as large as a child's head was found in the abdomen. This consisted of omentum, the transverse colon and small intestine bound together by inflammatory exudation. The inflamed peritoneum was invaded everywhere with military tubercles. There was no ovarian or uterine disease. There was some tubercular ulceration of the small intestines, the other abdominal organs were not affected. The pleura was also invaded with scattered military tubercles. In both lungs there were some tubercles.

This, then, was a case of encysted tubercular peritonitis simulating ovarian or parovarian cyst. The failure to recognize the true condition was ascribed to want of attention to the previous history of the case, and the recognition of the fact that there had been free fluid in the peritoneal cavity at the first visit.

The speaker then referred to the few similar cases which had been reported. In these cases the disease has appeared, as a rule, under the age of twenty-five years. It has progressed rapidly, the length of time varying from six weeks to eight months.

CASE II. F. R., aged twenty-four years, was admitted to the hospital in July, 1883. She claimed to belong to the colored race, but looked much like a white woman. She had been married one year, but had never been pregnant. There was no evidence of uterine disease. The abdomen was much enlarged, measuring forty-seven inches just below the umbilicus. Vaginal examination showed the uterus pushed forward by a sac containing fluid. There was apparently an immense unilocular sac. This had been first noticed seven or eight years before. The increase in size had been gradual, and unaccompanied with pain.

As to diagnosis, ascites was dismissed both by the

physical signs and the absence of any cause to account for such a condition. The length of time which the affection had lasted was against its ovarian origin. There are, however, exceptional cases in which an ovarian tumor may be present for a number of years, even as many as twenty-four, without requiring operation. While the age of the patient, the length of time which the cyst had been present, the marked fluctuation and the flaccid nature of the tumor was in favor of a parovarian cyst, there was one point against this diagnosis, and that was that although the cyst was flaccid, it could not be compressed below the umbilicus. Fibro-cystic tumor was readily excluded. The history of the case was against the existence of encysted peritonitis. The balance of evidence seemed to be in favor of an ovarian or parovarian cyst.

On July 13th, the operation was performed. It was made largely with the view of exploration. The peritoneum was found much thickened and closely adherent to the sac. With difficulty the adhesions were separated for a short distance and the cyst presented the appearance of an ovarian cyst. A trocar was introduced and forty pounds of a greenish, viscid fluid removed. An endeavor was made to enucleate the cyst, but the adhesions were so extensive that this could not be accomplished. The cyst was then incised to the extent of the abdominal opening, and on looking into it, it appeared to occupy the whole abdominal cavity, stretching tightly over the spinal column. A small portion of the wall of the cyst was removed, a drainage tube introduced and the opening closed with stitches. Peritonitis ensued and the patient died. A post mortem was made, but owing to the speaker's unavoidable absence, was not sufficiently full to throw any more light upon the case than had been obtained at the operation. The nature of the cyst, therefore, remained unsettled.

#### DISCUSSION.

DR. EMMETT, of New York. — I will say a few words in regard to the difficulties of diagnosis. It seems to me that the older I get and the more experience I have, the more uncertain I am about diagnosis. While yesterday I did not favor opening the abdomen, yet when a woman has an abdominal tumor I favor opening the abdomen to make the diagnosis, because she has something which must come out. As regards rapidity of development, we cannot depend on that. I have seen parovarian cysts develop in six weeks, and recover after operation. I have also seen cases which had lasted twenty-three years. I have twice opened the abdomen expecting to find an ovarian cyst and found a fibro-cyst. About two years ago I saw a case in which I could not make a diagnosis. The abdomen was opened and I saw just such a cavity as has been described. It seemed as though a cyst had at some time ruptured and its contents had become encysted. The cavity was left open, frequently washing it out. In six weeks the cavity had greatly diminished. Unfortunately the patient died at this time from strangulation of the small intestine. There is no set of symptoms which we can say belongs exclusively to a certain condition.

DR. WILLIAM GOODILL, of Philadelphia. — Our President seems to have been somewhat ashamed that he did not make the diagnosis in the first case. I can tell him that I have removed tumors the nature of which I do not know to this day. In one case I

worked for forty-five minutes before I found out what the tumor was. It turned out to be two ovarian tumors which had coalesced, including the uterus between them. I feel more and more the necessity of performing the exploratory operation, for it is impossible to make a correct diagnosis in many of these cases. To illustrate the difficulties of diagnosis, I shall report a case which I saw some time ago. A lady presented herself with a solid tumor of the abdomen. There was also metrorrhagia and menorrhagia. I diagnosed a fibroid tumor of the uterus, but the growth was so mobile as to suggest the possibility of a fibroid tumor of the ovary, and I so noted it in my record book. I advised against an operation. The lady went North and her sufferings became so great that she consulted a distinguished gynecologist, desiring an operation. He wrote to me asking my diagnosis. I told him what I thought of the case. He performed the operation, removing a large fibroid of the ovary, there being no adhesions.

DR. T. A. REAMY.—I wish to put on record another case in which a fatal result followed aspiration in tubercular peritonitis. The patient was a man, but it presented all the characteristics of an ovarian cyst. The patient died the second day after the removal of the fluid.

There is great difficulty in the diagnosis of these abdominal tumors. In reference to the coagulability of fluid from other sources than fibro-cystic tumors of the uterus. In a case which I saw some years ago, I tapped a woman and obtained a large quantity of pure blood; this coagulated at once; the patient recovered and is still living. My inference is that this was a case of tumor of the omentum.

DR. HOWARD.—It is agreed by all that cases often occur in which the diagnosis cannot be accurately determined, but in the majority of cases, I think a correct diagnosis is made. The fact that I was able, in these cases, to eliminate so many of the ordinary conditions which give rise to these tumors, shows that we have the means of making the diagnosis. The object of the paper was to give an accurate account of this case, in order that it might assist others in cases of obscure abdominal tumors.

#### THE CARE OF THE PERINEUM DURING LABOR.

By DR. T. A. REAMY, of Cincinnati.

The speaker referred to the various opinions which had been expressed on this subject. There is a general agreement as to the importance of preserving the perineum. In certain cases, however, from anatomical and pathological conditions, laceration is almost inevitable.

The author then referred to the various methods which had been proposed, dividing them into two general classes, those which aimed to support the perineum and those which are used with the object of retarding the progress of the head. There is one class, numerically small, who believe that the perineum should be let alone.

The method about to be described he had adopted several years ago and it had given him much satisfaction. He was persuaded that he had saved many perineum through its use. It was recommended for primiparae and others, where the structures were greatly imperilled. During the early part of the second stage, the patient is allowed to assume any position she prefers, but when the head begins to distend the perineum, the

patient is placed across the bed with the limbs in the lithotomy position, with the exception that the knees are kept close together. This is important. The limbs are held in this position by two assistants. A piece of muslin or a towel, ten inches wide and forty or fifty inches long, is carried around the buttocks of the patient and over the hemisphere produced by the bulging perineum, with the upper edge on a level with the fourchette, and the ends given to the assistants. They are instructed to make traction during the pain in the manner that the accoucheur may direct. The bandage must be applied smoothly. The direction of the force may be made in any required direction. Care must, however, be taken that the pressure is equally distributed, and that the assistants do not simply pull on the middle or posterior part of the bandage while the anterior portion is left lax.

In order to show that this procedure was based on good anatomical grounds, the speaker next referred to the anatomy of the perineum, illustrating his remarks with diagrams. According to the old descriptions of the anatomy of this region, it was considered that the muscular fibres decussated in the part between the vagina and rectum. Recent observations show that this is not the case, but that the fibres simply meet, and a laceration of the perineum divides no muscular fibres transversely, with the exception of those of the transversus perinei. The fibres are simply separated. When the sphincter is divided, its fibres are, of course, divided transversely. The perineum is prevented from laceration by the protection afforded by the tissue below and the integument. The bandage used in the way described affords a supplementary perineum, as it were. By keeping the limbs in the position indicated, Nature is able to supply tissue for the relaxation of the perineum. When the perineum is bulged, the lateral and posterior sulci disappear, and the perineum with the advancing head forms almost a hemisphere. The towel is in contact with every part of this hemisphere. The advance of the head may be retarded by making traction on the towel. Where it is accessible, a narrow bed may be used with advantage, the assistants taking their positions near the head of the patient. The use of this bandage avoids any tendency to exciting expulsive efforts from reflex irritation of the perineum, as is sometimes seen where the fingers are used. It is comfortable to the patient, and does not cause more exposure than other methods. The bandage may be kept on until the shoulder is delivered, thus avoiding rupture from this cause. In order that this method shall be successful, it is important that every detail shall be carried out with painstaking care. Should a rupture occur, the immediate operation should be resorted to.

The discussion of Dr. Reamy's paper was postponed until the afternoon.

#### AFTERNOON SESSION.

DR. WILSON, of Baltimore.—All agree that the perineum should be supported, but there is a great variety as to the way in which this support should be made. Dr. Reamy's method appears to be very practical, and it has the advantage of leaving the operator free to watch the case.

DR. MANN.—The method of Dr. Reamy seems to be a good one in a certain proportion of cases, but I am sure that I have seen some cases where it would have been of no avail. The worst ruptures that I have seen have occurred in cases where, at the time of the expul-

sive pain, the woman has torn herself from the accoucheur, and when he comes to examine, he finds the head delivered and the perineum torn. In such cases, the use of chloroform would, of course, obviate the difficulty. Another objection to the method is, that it requires more assistance than can always be secured.

DR. JOHNSON.—I have made a few investigations in regard to the necessity of supporting the perineum at all, and I have found that perhaps more lacerations of the perineum occur in the practice of physicians who support the perineum, than in the practice of midwives who do not support the perineum.

DR. CHADWICK.—I think the term, supporting the perineum, a misnomer; what we mean is retardation of the child's head until the tissues can be sufficiently stretched to permit the passage of the head. I always insure the slow exit of the head, and do not permit it to escape during a pain. The method which I employ is to have the patient on her side, and then pass one arm over the thigh and then by interlocking the fingers, I can make any desired amount of pressure. I hold the head back until the perineum is sufficiently stretched.

DR. ELWOOD WILSON, of Philadelphia.—I think I have tried every method suggested for the support of the perineum, with the exception of the one just described by Dr. Reamy. My usual plan is simply to instruct the woman to keep her mouth open during a pain.

DR. REAMY.—In reply to the statement of Dr. Chadwick that supporting the perineum was a misnomer, I would say that the word "support" means protection or succor, and I used it in this sense. The number of assistants required has been objected to, but the importance of preventing rupture of the perineum during the first labor is so great, that even if two or three skilled assistants were required, I think they should be employed. Skilled assistants are, however, not required. With this method the patient cannot get away. An objection to this method referred to by Dr. Chadwick is, that the pressure is not made over the perineum, but over the head, and in the efforts to retard the head, extension may be produced, causing delivery of the head in a bad relation to the axis of the outlet. The method I have mentioned obviates this. By this method, the head can be retarded as much as may be desired.

Again, let me call attention to a clinical picture familiar to all, in which the head has been permitted to remain pressing on the perineum for from half an hour to two or three hours until the perineum is stretched to the degree described in the paper. The tissues are then in a state of beginning necrosis and exceedingly friable. Even in such a case, the use of the towel or bandage lessens the perils of the perineum, and the perineum will often be saved where otherwise it would have been torn. You cannot support it by the hand under such circumstances. If it is desired, the forceps may be applied with the bandage in position.

#### REPORT OF A CASE OF CÆSAREAN SECTION.

DR. EDWARD W. JENKS, of Detroit.—The speaker described the following case which he had seen in consultation. The patient, aged twenty-seven, had given birth to one child five years previously without special difficulty. Two years later she received a fracture of the ilium from a building falling on her. She was taken in labor at three o'clock in the morning. The physician in attendance finding some difficulty tried to apply the forceps. He got one blade on without dif-

ficulty, but could not after several trials introduce the second blade. He sent for assistance, and the attempt to apply the forceps was again made without success. The cause of difficulty was a projecting shelf of bone at the seat of fracture. Another physician was called in and the forceps were again tried. It was then decided to try craniotomy, which was done, but still the head could not be made to descend. Dr. Jenks was then sent for. He tried to apply the forceps to make sure that they could not be applied, and failing, tried the cephalotribe with no better success. It was then decided to perform abdominal section. This was performed at two o'clock that night, twenty-four hours after labor began. The woman appeared to be in good condition. The incision was made through the abdominal wall and the uterus opened. The placenta was attached directly under the incision, and there was alarming hemorrhage, which however, was quickly checked by the rapid delivery of the fetus. The edges of the uterine incision were brought together by silk sutures and the abdominal wound closed. The patient did well until three days after the operation when she suddenly died. It was subsequently learned that the nurse had in disobedience to orders temporarily left the room, and in her absence the patient got out of bed. She complained of feeling something give way, and experienced severe pain, and died in a few hours.

#### DISCUSSION.

DR. SKENE, of Brooklyn.—I think that in such cases the chances of the patient are lessened by undue efforts at delivery by the forceps.

I think that this would have been a good case for the performance of laparo-elytrotony. It is impossible to sacrifice the child by that operation if it is performed in good time. I can hardly imagine any case where craniotomy should be performed except possibly where the head is so engaged in a small inferior strait that it can be delivered in no other way. Even then I am not certain that the Cæsarean section would not be the best operation.

DR. JENKS.—The operation of laparo-elytrotony was discussed, but it did not seem to be an easy operation under the circumstances. If it had not been for the unfortunate accident in this case, I think that the woman would have recovered.

DR. ELWOOD WILSON, of Philadelphia, read a paper on

#### THE USE OF TARNIER'S FORCEPS.

Dr. Wilson had at the meeting in 1881, read a paper in which he offered a number of objections to the use of these forceps. His objections had been based on theoretical grounds. The object of the present communication was to report nine cases in which he had used the forceps with decided advantage to the patient. He had therefore modified his views.

A detailed account of the nine cases in which the forceps had been used was then given. The instrument used has been Dr. Howard's modification of Tarnier's forceps.

DR. NELL, of Baltimore, exhibited his modifications of the Tarnier forceps which consisted in adapting the Tarnier principle to the Simpson forceps.

DR. MAXX.—I have used the Tarnier forceps for the past two years in a number of cases, with, in the main, satisfactory results. In one case I had a little misfortune which might not have happened with other

forceps. It was a case of deformed pelvis in which the Tarnier forceps were applied. The child was finally delivered and the woman made a good recovery. The child was however injured by the forceps. The outer edge of the orbit had been crushed in, destroying the eye. The child was living at the time of birth, but subsequently died.

The president, DR. HOWARD, of Baltimore.—So far as I know, I was the first one to use the Tarnier forceps successfully in America. I think that in cases of occipito-posterior positions, the application of other forceps, interferes with the rotation of the head, but with the Tarnier forceps the head is free to rotate.

#### EVENING SESSION.

At the business meeting held Wednesday evening, the following business was transacted.

Officers elected:

*President.* Thaddeus A. Reamy, of Cincinnati;

*Vice presidents.* Theophilus Parvin, of Philadelphia, and George J. Engleman, of St. Louis.

*Secretary.* Joseph Taber Johnson, of Washington, D. C.

*Treasurer.* Matthew D. Mann, of Buffalo.

*Council.* Frank P. Foster, of New York; B. B. Browne, of Baltimore; J. C. Reeve, of Dayton, O.; R. B. Maury, of Memphis, Tenn.

Next meeting will be held at Baltimore, September 21, 22 and 23, 1886.

*New members.* J. B. Hunter, of New York; Chas. Jewett, of Brooklyn; W. H. Parrish, of Philadelphia.

#### THURSDAY, THIRD DAY. — MORNING SESSION.

#### A MODIFICATION OF EMMETT'S CERVIX OPERATION IN CERTAIN CASES, WITH A CASE.

By DR. R. STANSBURY SUTTON, of Pittsburg.

Although the operation was original with him, he did not claim it exclusively.

Cicatricial tissue is found in every old laceration. It is found not only at the angles where it is readily removed, but also in the tissue of the flaps. This is especially true where nitrate of silver applications have been used. Sometimes the cicatricial tissue is more marked on one lip than on the other. The case described was that of Mrs. —, age forty-two, the mother of several children. There was double laceration of the cervix. The anterior lip was hypertrophied and as hard as cartilage. It was convex from side to side and from before backward. The posterior lip, which was not the seat of much cicatricial tissue, was denuded in the usual way. The anterior lip was denuded entirely across. The strip of mucous membrane was left wider than usual. The lips were united in the usual way. The result was excellent.

The speaker thought that in some cases this was the only method which would remove all the cicatricial tissue.

#### DISCUSSION.

DR. GOODELL, of Philadelphia. — I have resorted to this device on several occasions. In two or three cases I have dissected up a portion of the mucous membrane, then removing the indurated tissue and bringing the flaps together. This was followed by good result. I have never yet removed both surfaces, although I believe that it has been done.

I should like to have the opinion on one point. I have frequently met in the operation with distended Nabothian follicles, and it has been my custom to remove these follicles. This sometimes leaves an attenuated cervix. I would ask in regard to the removal of these glands.

DR. SKENE, of Brooklyn. — I would offer a criticism on the term cicatricial tissue. The tissue is not cicatricial. It is simply hypertrophied and indurated tissue. It is a true sclerosis. A great deal can be done to remove this tissue by preparatory treatment. Diseased Nabothian glands should be removed in the same way. There are cases in which some plan is necessary to permit the approximation of the lips. The plan I have adopted has been to perform a preparatory operation consisting of the removal of a transverse V-shaped piece of from one or both of the lips. One or two sutures are introduced and the patient is allowed to go about after the first day. The stitches are removed in a week or ten days. After the enlarged cervix is reduced, the ordinary operation is performed.

DR. ENGLEMAN, of St. Louis. — I have found the condition referred to very frequently. I now cut deep and remove this tissue in old, severe cases. In such cases it is impossible to preserve the strip of mucous membrane. I have removed the mucous membrane and indurated tissue from both lips. In some cases there has been complete union all the way across. The passage of a probe on the third or fourth, or eighth or tenth day will keep the canal open. In such cases I now insert a single piece of No. 8 braided silk. A probe passed a few times after removal of sutures will dilate the opening.

The result in these cases has been good union, involution, and good health of the patient. I do not know that these patients will conceive.

DR. MANN. — In some of the cases where the anterior lip is hypertrophied and the posterior lip is normal, it is very difficult to bring the parts together. In such cases I have tried the suggestion of Dr. Sutton and in only one case have I found it necessary to denude both lips. In order to prevent union I inserted a piece of small drainage tube. This case did well.

In affection of Nabothian glands, if I have time I institute preparatory treatment, but where there is want of time, I remove the glands at the time of operation. I have never done this on both lips. In my cases the result has been good.

DR. GOODELL asked Dr. Sutton if he had seen retroversion cured by Emmet's operation. The speaker had seen such result.

DR. BAKER. — I think that the strip of mucous membrane is important. The method of Dr. Sutton will tend to make a curved canal. If the patient is properly prepared, there will be no necessity for performing Dr. Sutton's operation. Even where the lips are hypertrophied, I think Emmet's operation can be done by adopting the suggestion of Dr. Skene. I, however, prefer to do both operations at the same time.

DR. HOWARD. — I have seen Dr. Harry Sims operate in the presence of his father. A glass tube was introduced to prevent union between the denuded surfaces.

DR. SUTTON. — In reply to Dr. Goodell, I would say that I have seen retroversion cured by Emmet's operation.

## INFLAMMATION OF PAROTID GLANDS FOLLOWING OPERATIONS ON THE FEMALE GENITAL ORGANS.

By DR. WILLIAM GOODELL, of Philadelphia.

Reference was then made to the close relation between the salivary glands and the genital organs of the adult: A number of cases were referred to in which this complication had followed operation on the genital organs of the female.

In a case of posterior incision of the cervix, suppuration of the parotid glands followed. The condition seems liable to follow ovariectomy.

In 153 cases of ovariectomy, he had observed a parotid bubo. This followed ovariectomy in a woman who had been twice tapped, the second tapping being followed by septicæmia. The operation was performed as a last resort. The swelling of the parotid appeared on the seventh day. The patient was removed by her friends and died on the twenty-second day.

There are other cases in which there is transference of irritation to the parotid glands in which there is no septic symptoms.

One case followed ovariectomy, another case followed oophorectomy, a third case was reported.

None of these cases ended fatally, and the condition was regarded as sympathetic and not symptomatic.

A case was reported in which swelling of the parotid followed operation on laceration of cervix. The patient recovered. The condition was followed by hysterical trismus.

## DISCUSSION.

DR. SUTTON. — I have seen one case of swelling ending fatally in twelve ovariectomies. I attributed this to septicæmia.

DR. JOHNSON, of Washington. — I have seen one case in which three or four days after ovariectomy, swelling of the parotid glands followed. The patient died on the sixth day.

DR. MANX. — I have seen three cases. In the first case there was distinct septicæmia resulting in death before suppuration of the enlarged glands. The second case followed removal of ovaries and uterus above the internal os. The patient made a good recovery. The third case was in a boy who had received a wound of the abdomen. This was followed by recovery.

DR. EMMET. — I have seen the swelling follow operation on lacerated cervix. There was recovery. The second case followed operation on a small vesico-vaginal fistula, resulting in death.

DR. REAMY. — I would report two cases, one following Tail's operation, the patient dying. The second case was one of removal of uterus and ovaries, the patient recovered. Suppuration of the glands did not follow.

DR. JAMES R. CHADWICK, of Boston, read a paper entitled

## PERISTALSIS OF THE GENITAL TRACT AND A NEW THEORY TO EXPLAIN RELAXATION OF THE VAGINAL OUTLET DURING LABOR.

The speaker had seen two cases which had directed his attention to this point. The first was a primipara with rigid outlet. In two hours the outlet relaxed, although the head had not escaped from uterus. The second case was one of fibroid tumor in which ergot was given. There had been previously a small outlet. Coincident with the uterine contraction and the forcing

down of the tumor, there was relaxation of the outlet. This disappeared when the ergot was stopped.

This and other observations had led him to explain the relaxation of the vaginal outlet by a peristaltic action similar to that seen in the Fallopian tubes and other portions of the genital tract.

## DISCUSSION.

DR. GOODELL said: A thing that appears to clear out the point taken by the speaker, is that when a piece of placenta or membrane is left in the uterus after abortion or labor, the cervix remains funnel-shaped, showing the contraction of the womb. This I regard as pathognomonic.

DR. THEOPHILUS PARVIN, of Philadelphia, described a case of

## FACIAL PARALYSIS IN AN INFANT FROM THE USE OF THE OBSTETRIC FORCEPS.

The speaker was called to a case of difficult labor in March, 1885. It was stated that the first stage had lasted twenty-four hours and that the second had been in progress eight hours. It was a vertex presentation, with the occiput anterior and to the left.

The uterine pains were feeble and infrequent. The forceps were applied, and a living child weighing seven and a half pounds was delivered. The following day it was noticed that the left side of the face was paralyzed, although scarcely a trace of pressure from the forceps was observed. The trouble disappeared within ten days.

A complete *résumé* of the literature of the subject was then given.

DR. GOODELL. — I have seen several instances, and in all the trouble has been on the right side. I explain this by the fact that the two most frequent positions are with the occiput anterior and to the left, and occiput posterior and to the right.

DR. SKENE. — It is important to make the diagnosis between facial paralysis from injury and facial paralysis from apoplexy, for, as is well known, this condition is most common at the two extremes of life, infancy and old age.

After votes of thanks to the officers the Society adjourned to meet in Baltimore next year.

## SUFFOLK DISTRICT MEDICAL SOCIETY. — SECTION OF OBSTETRICS AND GYNECOLOGY.

ROBERT R. DIXON, M.D., SECRETARY.

MAY 20, 1885. The meeting was called to order at eight o'clock. DR. JAMES R. CHADWICK, in the chair. DR. R. A. KINGMAN read a paper entitled:

ANÆSTHETICS IN NORMAL LABOR.<sup>1</sup>

DR. FIFEELD, in opening the debate, said that the use of chloral in obstetric practice was comparatively new, and the results gleaned from Dr. Kingman's paper would lead him to use the drug more frequently than had been his custom. That the women to whom chloral had been given were less liable to hæmorrhage was a strong argument in its favor.

Regarding the use of ether, he is inclined to take issue with Dr. Kingman. In years gone by he had used ether to a considerable extent in labor, but now he has abandoned its use largely, administering it only

<sup>1</sup> See page 337.

when he considers it absolutely necessary. He thinks it almost impossible to give ether in a moderate degree in childbirth. The demand for it when once given is like the passion for drink. The woman will cry for it, and seize upon the sponge, and inhaling with greediness pass into profound stupor. If the physician demand the intelligent aid of the patient, he cannot gain it, for the effect of the drug does not pass off between the pains. Dr. Fifield mentioned the case of a woman with retained placenta. Ether had been heavily given in a most difficult forceps case. Haemorrhage had come on and the placenta not yet expelled. Nothing could induce her to remain on her side, or near the edge of the bed, or even to bend the knees, equally impossible to put her on her back at the edge of the bed. The situation was one of peril. The operator was thankful to have escaped from it with the woman safe, and his arm unfractured from the wild tossings of her great bulk. Until recently he had believed death from ether properly administered impossible, but lately he had seen respiration so quietly cease that the intelligent gentleman standing at the patient's side had scarcely noticed it. Under most active and protracted artificial respiration recovery ensued.

A seeming death he had seen in Paris from chloroform was not more quiet, both heart and respiration ceasing, until M. Ricoud, precipitating himself on the body, by artificial respiration substituted life for death. Curiously enough both these cases took place at operations for phthisis. Dr. Fifield did not consider ether proper in ordinary childbirth. Dr. Jacob Bigelow had spoken of the great comfort gained by the woman who should inhale cold water from a hollow sponge.

Dr. WELLINGTON remarked that he agreed in opinion with the former speaker, that the free use of ether was not unattended with danger. He instanced the case of an elderly woman, who was undergoing an operation for a uterine trouble. She was under ether, carefully administered, when suddenly the pulse stopped. Brandy was injected subcutaneously, and other methods were taken to revive her. Fortunately she recovered; but matters looked badly for a time. This is the only case in which he had used ether, when the results seemed in any way likely to be serious.

He was surprised at the statement made by the reader that ether never stops labor pains. He certainly has seen cases where it did stop them, even when administered in small amounts, and where its use had, on this account, to be discontinued.

When ether is once given, as already remarked, a woman becomes sometimes so unreasonable and unmanageable as to occasion great embarrassment. This is a serious evil and deserves special mention in this connection.

Dr. Wm. L. RICHARDSON expressed his regret that he had not heard the first part of the paper, and that he must disagree with the reader in some of the conclusions at which he had arrived. In private practice he of course gave ether if the patient desired it, but if the management of the case was left to his own judgment he did not use it in the course of a natural labor. He had never been able to obtain the results which Dr. Kingman described; namely, the relief of pain without at least a partial loss of consciousness. During the first stage of labor he had been in the habit for a number of years, both at the Boston Lying-in Hospital and in private practice, of using chloral, and in the

great majority of cases with very satisfactory results. The use of ether in the second stage, in his opinion, lengthened the labor and predisposed the patient to the occurrence of post-partum haemorrhage. He agreed fully with the statement made by Drs. Fifield and Wellington. If it was thought best, however, for any reason to use ether, or if the patient in private practice desired it, he had always been in the habit of giving it as Dr. Kingman had described, which, so far as he knew, was the usual method of using it in obstetric practice.

Dr. KELLY said that as obstetric practice was chiefly in the hands of the special accoucheurs in Dublin, his experience was comparatively limited, but he had had more opportunities of observing the effects of chloroform than of ether when administered during parturition, and he considered that even in moderate quantities the former diminished the vigor and the duration of the uterine contractions. In Ireland these agents were only used in obstetrics when demanded by the exigencies of the case. In surgical practice, his experience, both of chloroform and ether, was very extensive, and on one occasion he had the misfortune to lose a patient during chloroform anaesthesia. Although he had seen imminently dangerous symptoms arise from ether he had never witnessed a fatal termination. He had observed that in patients who did not readily respond to the influence of ether, the alarming symptoms were due to the tetanic spasm of the respiratory muscles rather than to cardiac depression.

Dr. SWIFT said he preferred to use chloral in normal cases, giving it in the first stage. He was unable to get the effects spoken of by Dr. Kingman from the use of ether in small doses, it on the contrary rendering the woman uncontrollable, so that he seldom used ether except in cases requiring an operation where the full anaesthetic effect was desired.

Dr. DRAVER stated that his practice had been to withhold ether until the closing pains of the second stage of the labor, when, as the head emerged from the vulva, the woman's sufferings most urgently demanded relief, and when the progress of parturition could not possibly be retarded by the anaesthetic. Judging by the usual experience in the administration of ether in surgical cases, the exhilarating effects of ether, given as the reader recommended, would prove, on theoretical grounds, a drawback rather than an aid.

Dr. HODGSON considered that ether, when given in sufficient quantity to ease pain, retards labor. His practice is to administer ether when the head is about passing the perineum, if the woman demands it. He has never seen post-partum haemorrhage resulting from its use, and thinks the safety of the perineum is promoted by that course.

Dr. BARNES stated that he always permitted the woman to hold the sponge, and when she was sufficiently under the influence it would drop from her grasp. Never had he thought that labor was retarded in cases where he had used it, and the amount used was absolutely under his control, thus securing the degree of anaesthesia desired. The alarming effects noticed by Dr. Fifield in two cases, one where chloroform, the other where ether was used, would be more instructive had the patient under ether been subjected to the close observation at the time respiration ceased, as was practised in the chloroformed case.

DR. REYNOLDS said, of what use is it to speak of the acknowledged dangers from the administration of ether. Post-partum hemorrhage is the result of exhaustion, and nothing tires a woman so quickly as pain. Relieve the pain with ether and you prevent the exhaustion. It is criminal not to use it in a moderate amount. If a woman in labor is brought in from the street and has post-partum hemorrhage, it is from exhaustion and not from ether. One of the most eminent accoucheurs, Fordyce Barker, gives ether in every obstetric case which he attends, and, as yet, has not had a case of post-partum hemorrhage.

Dr. Reynolds said that a rigid os with the head pressing upon it will dilate in five minutes under ether, which should be given till the patient snores. If the pains ceased or greatly diminished he would withdraw the ether. Much worry and uneasiness is caused by the notion being advanced that ether causes post-partum hemorrhage. Ether does delay the labor to a slight extent, but not for years has he found it necessary to withdraw the ether after he has commenced its administration. Why let the woman suffer, even if the ether does delay the labor one-half hour. It is the duty of the physician to remain by his patient and watch the uterus, and post-partum hemorrhage will not occur. If ether is given cautiously it will not check the pains.

In reply to a question by Dr. Broughton, Dr. Reynolds said that the new method, as it is called, of giving ether, is to administer it during the first and second stages when the woman is likely to become exhausted and when other remedies do not act. So long as uterine contractions are recurring he continues the ether, resting between the pains. His method is to keep his finger in the vagina and give the ether when he feels the uterus contract.

Dr. TEMPLE remarked that he tried the plan, recommended by Dr. Kingman, in six cases, and in none of these had there been the least difficulty in restraining the patient, and the results had been beneficial.

Dr. BUNDY said that he always permits the patient to hold the sponge herself, and in the intervals between the pains he removes it. He has never had the least trouble.

Dr. J. R. CHADWICK stated that he was in the habit of allowing his patients to inhale a few whiffs of ether during the pains in the expulsive period of the labor, as recommended by Dr. Kingman, for the purpose of alleviating their sufferings. And at this time and in this way ether did not seem to retard the delivery appreciably or to predispose to subsequent hemorrhages. He saw no reason for the reader's practice of withholding the ether during the most painful stage of all—the expulsion of the head from the vulva. At that period it was specially desirable to prevent any straining on the part of the patient so that the head shall emerge very slowly between the uterine contractions, when the obstetrician has absolute control of the speed at which the head should advance. By the aid of ether at this time there is much more certainty of escaping rupture of the perineum. To patients who are frail or exhausted in the earlier stages of labor and are clamoring for the relief to suffering afforded by ether he is very loath to administer it, because it is very hard to intermit its use subsequently, because the momentary anesthesia, obtained from a few whiffs at a later stage, rarely suffices, because a more profound etherization certainly interrupts the frequency of the

pains and thus retards the labor, and because he does not feel assured that the deeper and more prolonged anesthesia may not predispose to flooding. This last effect he does not, however, regard as well attested.

In the earlier stages of labor when a patient's condition of exhaustion demands rest from her travail he is more disposed to rely upon chloral or even subcutaneous injections of morphia, which latter drug will completely interrupt the progress of the labor for five or six hours.

Dr. REYNOLDS remarked that he did not wish it to be understood that he always gives ether in the first stage of labor, for he seldom administers it at that time, but commences when the woman's sufferings are severe. Rest in the intervals between the pains is very important, and much is gained if the woman shall fall asleep between the pains.

Dr. FIFIELD thought that there was a spice of sophistry beneath the music of the oratory of Dr. Reynolds. The word that had fallen from the lips of the venerable Barker was one of terror. It was exhaustion! No word, says one of the fathers of the Obstetric Art, is so much abused in the lying-in-room as the word "Exhaustion." Like Figaro it is here, it is there, it is everywhere. As to flooding, to say that it is the result of exhaustion is absurd. Who that remembers long protracted forceps and craniotomy cases has marked that they were followed by flooding? Hemorrhage comes to the stout, to the feeble, to the strong, to the well-fed, and the ill-fed alike. Who can predict it? Has it not followed the easiest labors; as well as the most protracted. Nay, even more frequently. The testimony of the best obstetricians amongst us is that etherization tends to bring about flooding, and no eloquence can gainsay that testimony.

Dr. KINGMAN, in summing up, said he could not understand the difficulties mentioned by several of the gentlemen who had taken part in the discussion. In his hands, ether had never failed to relieve suffering, even when given in the small doses advocated, and he had never observed the uncontrollable "passion" for ether. He is accustomed to make use of an Underwood Inhaler, which permits accurate estimation of the dose. This the patient is allowed to hold, the desired effect being attained by regulating the dose of ether for each pain.

The stage at which ether is to be given must depend upon the exigencies of the case. If much time is to elapse before delivery, he gives chloral, if not, or if chloral fails to give relief, he administers ether. Humanity demands it.

He does not advise stopping the ether when the head is passing the vulva, but that it be partially withdrawn if necessary to insure the entire cooperation of the patient. If the pains are extreme or the patient is unruly he pushes the ether to unconsciousness.

Dr. CHADWICK exhibited a sessile fibroid tumor as large as a pear which he had enucleated from the posterior lip of the uterus of a lady before. Being uncertain as to the depth to which the tumor was imbedded in the tissue of the uterine wall he had adopted the expedient of splitting the tumor with the bistoury, extending the incision above the apparent line of insertion of the cervix; then making a transverse incision through the attenuated cervix down to the fibroid at a point lower than the point to which the central incision of the tumor extended, he passed the handle of his bistoury between the uterine tissues and the fibroid, and

readily enucleated the tumor from its bed. By this method of procedure he had escaped the common difficulty experienced in such operations of determining where to cut so as not to take away a portion of the cervix, or to leave a portion of the tumor. There was no appreciable hæmorrhage.

# THE NEW YORK ACADEMY OF MEDICINE.

STATED meeting, October 1, 1885.

## ADDRESS BY THE PRESIDENT.

The President, DR. A. JACOBI, delivered an address in which he gave a warm greeting to the Fellows on reassembling after the summer vacation. He then spoke for some time in regard to the work of the Committee for Collective Investigation of the International Medical Congress of 1884, of which he and Dr. N. S. Davis are the American members, dwelling upon the difficulties encountered in such investigations and the usefulness of their results. The following were the special diseases whose geographical distribution and etiology were to be studied: rickets, chorea, acute rheumatism and cancer, and Dr. Jacobi has had a pamphlet issued which contains a series of questions, with blanks for reply, in regard to each of them. He also spoke of the Code question and the International Medical Congress of 1877, and concluded with some remarks on the affairs of the Academy.

The paper of the evening was by DR. R. VAN SANTVOORD, and was entitled:

## OBSCURE CASES OF WEAK HEART.

The first case narrated was that of a strong and fresh-looking man of forty-two years of age, who had the appearance of robust health. His occupation was that of a dry-goods salesman, and except that he took an occasional drink with a customer and ordinarily ate his meals too rapidly, his habits were good. He suffered from drowsiness, which would often come on during the day, and from frequent headache; while his mind was apt to be forgetful. He was also somewhat short of breath in going upstairs, and there were slight disturbances of the digestive functions. The heart-sounds (especially the first sound), were rather weak, and there was a distinct reduplication of the second. There was no valvular trouble, and the sphygmographic tracing was of no special significance. He was placed on ten minims doses, three times a day, of tincture of digitalis and of tincture of nux vomica; the latter being added on account of the digestive trouble. At the end of two weeks the heart-sounds were somewhat louder, but the general health was not improved. The remedies at first prescribed were then substituted by caffeine and strychnia, and under the use of these last he rapidly recovered. Afterwards when he felt the drowsiness or headache coming on, a few doses of caffeine soon dispelled the trouble.

The second case was that of a stock-broker, thirty-eight years of age, who came of a stout family, and had had several attacks of gout himself. He had been much harassed by business anxieties, and for the past four years had been in the habit of indulging very freely in the use of spirit. He was permanently gray, looking much older than he really was, and altogether exhibited a very haggard and careworn appearance. He complained of shortness of breath in going upstairs,

and it was ascertained that he had had some albumen in his urine, with occasional puffiness about the ankles, especially when he drank brandy. He was in the habit of taking from twelve to fourteen drinks of whiskey a day and eating but one meal during the twenty-four hours. When examined he was found to be suffering considerably from dyspnoea and wheezing. The first sound of the heart was weak, and the second hard and metallic. The urine was slightly albuminous, and of a specific gravity of 1024. One fatty cast was found.

There was great improvement in the patient when he stopped drinking whiskey; when he began to go about again, after resting for a time, the dyspnoea returned. He was then ordered two minims of tincture of digitalis three times a day, together with appropriate tonics, and in two days he was able to sleep flat on his back throughout the night. At the end of six months he had gained measurably in health and strength; though a small amount of albumen was still detected in the urine by means of the mercuric iodide test, and there were also found a number of hyaline casts. He had previously been rejected by an examiner for a life insurance company on account of the quickness of his pulse. The cardiac trouble was unquestionably the predominant feature, and the existence of grave disease of the kidney was considered improbable on account of the slight and varying amount of albumen in the urine, the normal quantity of the latter, and other circumstances which were noted in connection with the case. The sphygmogram of the patient was exhibited.

The third case was that of a gentleman fifty-four years of age, who had always been addicted to athletic sports, and had constantly enjoyed good health, with the exception of constipation. For a long time he had been obliged to get up in the night to urinate. He now suffered from headache and drowsiness, and was thin, sallow, and anxious-looking. There was found to be considerable dilatation of the left ventricle, and also a faint systolic murmur. The cardiac sounds were weak, especially the first sound, and the urine was albuminous. He sought medical advice on account of an intense pain in the vertex, and insomnia. Bicarbonate of soda and gentian were first prescribed, on the supposition that the headache was due to gastric derangement; but no relief ensued. The patient was then put upon the tincture of the chloride of iron with digitalis, and at once there was marked improvement in his condition. From the enlargement of the heart and the great quantity of urine passed, together with the amount of albumen found in the urine, it was inferred that the condition present was one of granular contracted kidney with resulting heart weakness. The sphygmographic tracings of the case were then shown.

After this the patient went to the South for some months. He held his own for a year, and at the end of that time it was found that there was no albumen in the urine, which was of a specific gravity of 1015; the quantity passed in the twenty-four hours being seventy ounces. Hence it was concluded that the polyuria was due to some other cause than granular contracted kidney, and probably to urethral trouble, as it was ascertained that the patient had a stricture, which he had contracted in the ordinary way thirty years before. The cardiac feature in this case, therefore, seemed to be of an independent nature.

The fourth and last case narrated was one in which

the symptoms were so striking that the trouble could hardly be called obscure. The patient was a boy of fourteen years who had recently recovered from the measles, and he was found to have a loud, blowing systolic murmur, with marked venous hum. There was cardiac dilatation present, such as is apt to occur in long-standing anemia; and the patient's sphygmogram showed a very remarkable degree of arterial tension.

The author of the paper now passed in review the group of cases described, and made a number of observations in connection with them. As to reduplication of the sounds of the heart, he said that reduplication of either one or the other of them was present in three out of the four patients. He referred to the various hypotheses which had been suggested to account for this phenomenon of reduplication, and expressed his agreement with Bramwell in the opinion that it was probably due to asynchronous action of the ventricles. In the third case there was marked dilatation of one ventricle, and was not difficult to see how, under the circumstances, it such asynchronous action was likely to occur. Apart from speculation, persistent reduplication of the first sound of the heart had been repeatedly noted in grave lesions of the cardiac tissue. Weakness of the first sound of the heart was found in three of the cases. In the second case the second sound was loud, and in the third weak, as the ventricles contracted more gradually in this instance.

Dr. Van Santvoord, in conclusion, made some comparison of the action of digitalis and caffeine on the heart. The latter he had found to slow the action and increase the amplitude and tension of the pulse. It seemed probable that it had a slighter influence upon the vaso-motor apparatus than digitalis, and, at all events, the fact remained that caffeine was sometimes efficient in cases where digitalis failed to act satisfactorily. He believed it to be a better and safer agent than digitalis in cases of acute disease where there was cardiac weakness. An eminent French authority had advised that it should be pushed until two grammes were taken daily.

In the discussion following the paper, Dr. JOHN C. PETERS referred to a case still under observation, of a gentleman over sixty years of age, who had always been careful in his habits and apparently enjoyed perfect health, though he had some reason to suppose that his system was not sufficiently well nourished. He was taken with acute pain in the epigastrium, and when called to see him, Dr. Peters was astonished at the remarkable weakness of the pulse and failure of the heart present. There was at first slight congestion of both lungs, which was followed by bronchitis, and some pulmonary oedema; but the temperature never rose above 102°. Dilatation of the right ventricle, with marked dyspnoea, rapidly developed, and the patient for a considerable time was in a very precarious condition. Since then he had greatly improved, so that he was now able to walk a mile, though the heart still remained weak. He had been treated with the ordinary remedies; and in regard to the use of nuxvomica, Dr. Peters remarked that it often seemed to act more efficiently than digitalis.

Dr. WEBER said that he had observed no effect from caffeine in cases of dilatation in connection with probable fatty degeneration of the cardiac tissue. He had, however, had good results from the action of digitalis, but he never used the tincture. The infusion, if

obtained from perfectly reliable sources, was in every way preferable; but the best preparation of all was undoubtedly Squibb's Fluid Extract. In delayed recovery of the heart after acute diseases, he had found caffeine very efficient, and the preparation of it which he was in the habit of using was the hydrobromate. This was generally employed in connection with appropriate tonic remedies. In conclusion, Dr. Weber spoke of the kind of cardiac weakness met with in men of over forty years of age and weighing more than two hundred and fifty pounds, when urgent dyspnoea arises from the deposit of layers of fat between the muscular fasciuli of the heart. The successful treatment of such cases was found to consist in the diminution of the amount of liquid taken, the regulation of the food for the purpose of reducing fat, and the employment of as much exercise (principally walking) as could be well borne.

Dr. E. D. HUNSON remarked that affections of the heart were not a complicated matter. Whatever might be the characteristics of the difficulty attracting attention, he thought that the experienced physician would at first apply all the tests for the detection of the presence of organic cardiac trouble. If, after a thorough examination, it were found that there were no evidences of organic disease, he would next investigate the condition of the various viscera in turn, commencing with the kidneys, and then passing on to the liver, stomach, and other organs. A very large proportion of the cases of temporary cardiac disturbance were undoubtedly produced by digestive troubles and perversion of assimilation. Especially had these a marked effect in bringing down the pulse, so that if a patient came to us with a pulse of 10, or perhaps only 32, it could be pretty safely predicted that a chologogue cathartic would promptly bring it up to the normal standard. If, however, no cause for the cardiac trouble could be found in any of the other organs, we would conclude that it was probably due to a derangement of the ganglionic action of the heart itself, from some defect in the blood-supply, and for this condition such remedies as digitalis, caffeine, and convallaria were appropriate.

Dr. GARRIST called attention to the importance of the prevention of such disease as constituted the present subject of discussion. The use of tobacco, he thought, was responsible for a very large number of these cases of cardiac weakness. In addition to guarding against the excessive use of this, it was also necessary that the diet should be of a proper character (the food being highly nutritious, but not stimulating), and that changes of temperature should be carefully provided against, especially by the wearing of flannel. At the same time the individual should avoid excitement. As to the remedies that were of most service in weak heart, he had obtained very satisfactory results indeed from the combination of tincture of digitalis with tincture of stramonium, as suggested to him by the late Dr. Valentine Mott.

Dr. A. A. SMITH said in regard to the use of digitalis, that it performed two distinct functions. In the first place, it affected the cardiac action, and, secondly, when given in small doses, it affected the cardiac nutrition.

Dr. FRUITRIGHT stated that some time since he had resorted with success to the use of tincture of the night-blooming cereus in a case of apoplexy followed by softening, in which no effect upon the cardiac weak-

ness present was produced by either digitalis or convallaria. Since then he had employed it repeatedly, and had always found it efficient. The dose was from three to ten minims.

Dr. VAN SANTVOORD closed the discussion, and in the course of his remarks he spoke of the case described by Dr. Peters as being one of great interest and instruction. It seemed to him probable that in this instance the cardiac weakness had been of long standing; but it was only when the acute attacks spoken of came on that the heart proved inadequate for its work. Under ordinary circumstances it was competent to meet the demands made upon it; but it was not able to stand the extra strains thus imposed upon it. Dr. Hudson had pointed out very clearly in his remarks the manner in which these cases should be studied; but he had reason to believe that the difficulty was not recognized as it should be by the mass of general practitioners, and it was on this account that he had thought it worth while to prepare the paper which he had read.

### Recent Literature.

*Laryngoscopy and Rhinoscopy in the Diagnosis and Treatment of Diseases of the Throat and Nose.* By PROSSER JAMES, M.D., Lecturer on Materia Medica and Therapeutics at the London Hospital; Physician to the Hospital for Diseases of the Throat, etc. Fourth edition, enlarged, illustrated with hand-colored plates. New York: William Wood & Company. 1885.

This is an excellent little manual. Nearly one half of it is devoted to a description of the necessary apparatus, the methods of making an examination, the history and the theory of laryngoscopy, etc. In the remainder of the 219 pages, the author discusses the practical uses of the laryngoscope, laryngoscopic therapeutics and operations. We think the beginner in laryngoscopy will find this a most useful book, as its pages are not over-burdened with descriptions of instruments of doubtful utility, nor are disputed points discussed in detail, while the essentials of what the student requires are given clearly and accurately.

It is convenient in form, the type is clear, and the paper good, but some of the illustrations leave much to be desired.

F. H. H.

*The Pathology, Diagnosis, and Treatment of Diseases of the Rectum and Anus.* By CHARLES B. KELSEY, M.D., Surgeon to St. Paul's Infirmary for Diseases of the Rectum; Consulting Surgeon for Diseases of the Rectum in the Harlem Hospital and Dispensary for Women and Children, etc. With two chromolithographs and nearly one hundred illustrations.

Dr. Kelsey is widely known as an active and energetic worker in the special branch of surgery to which he has devoted him-self through various contributions to periodical literature, and particularly as the author of a work on the same subject contributed by him to "Wood's Library of Standard Medical Authors" in 1883. The present volume is practically the same as that published in "Wood's Library," but "contains many changes, chiefly of such practical character as would naturally be suggested to a writer by the in-

creased experience which comes from the daily practice of a specialty."

"The chapter on Rectal Hernia has been added entire, and many new illustrations have been introduced."

The chief aim of the author has evidently been to collect from every available source all that is now known concerning the pathology and treatment of these distressing affections, adding his own views thereon, and methods of practice.

The book is clearly written, well illustrated, and contains many references to the latest contributions to this branch of special surgery. With regard to operations, and the treatment of the various affections described, Dr. Kelsey does not differ materially from the majority of modern surgical writers. In dealing with *internal hemorrhoids*, he prefers the injection of carbolic acid to any other mode of treatment, an operation we are inclined to regard with favor, although from a very limited experience, but not, however, to the exclusion of other well-tried methods.

Upon the whole, the work is a very complete treatise, and to be recommended as "a safe guide for the student and general practitioner."

—Advices from the Red Sea, in our English contemporaries, continue to describe the discomforts experienced at Suakin as very serious. The English soldiers, it is said, are "a pitiful sight," not one man in fairly healthy condition, while even the Indian troops are grumbling bitterly, and almost mutinous. The heat is tremendous, the frequent sandstorms most distressing, and the deaths very numerous. But if Suakin be bad, Massowah, which the Italians have occupied, is worse. A private letter says: "We called in at Massowah, and had to anchor for the night, and a more frightful, horrible night I never spent; not a breath of air, and the thermometer 122° Fahr. This is no exaggeration; we were panting about the deck; the heat seemed to choke you; sleep was out of the question. Some negroes seemed to feel the heat more than Europeans, and were groaning fearfully, and pouring buckets of water over their heads, which, however, was of very little use, as the water was between 93° and 100° Fahr. Five Italian officers have committed suicide, and no wonder! Aden, after Suakin and Massowah, is a perfect paradise."

—Dr. Cheize, in the *Glasgow Medical Journal*, writes that, wishing to remove an ingrowing toe-nail, and being without a spray-producer, he covered the toe with a pledget the size of a crown-piece, poured ether on it, and evaporated this by means of a pair of bellows; in five minutes anaesthesia was complete, and lasted while the nail was removed and the matrix seared with the actual cautery.

—As an example of fertility *Lyon Medical* (July 12) cites the case of a peasant woman who has brought forth 27 children, of whom 25 are alive and healthy. Six of this number are girls. Her best year of labor was the one in which she produced five children, three on January 24, and two on December 27. She is now 63 years of age and her husband 73.

283 WASHINGTON STREET, BOSTON, MASS.

## INSPECTION AGAINST SMALL-POX ON THE CANADIAN FRONTIER.

At the request of the Governors of several of the States, among them being Vermont, New Hampshire, and Massachusetts, the Secretary of the Treasury has appointed medical inspectors on the Canadian border, east of Lake Ontario, to inspect passengers arriving by rail from Montreal and other infected localities in Canada. These inspectors have been distributed as follows: Two on the trains of the Central Vermont Road between St. Albans and St. Johns; two on the trains of the Southeastern Road from Richford to Sutton Junction; one on the Passumpsic Road from Newport to Sherbrooke; two on the Grand Trunk Railroad, of whom one is stationed at Rouse's Point, and one travels on the trains from St. Johns.

Surgeon A. W. Austin, of the Marine Hospital Service, has established his headquarters at Burlington, Vermont, where during the continuance of the system of inspection, he will receive weekly reports from inspectors on all lines of railroads crossing the frontier, of the number of trains inspected, the number of persons examined, the number of persons vaccinated, number of pieces of baggage, furniture, etc.

The following instructions have been issued to the inspectors:

All persons bound for the United States coming from Montreal or other places in Canada where small-pox prevails, must produce satisfactory evidence to the inspector that they are protected by a recent vaccination, or submit to this operation before they are allowed to cross the boundary line.

Inspectors will vaccinate all unprotected persons, free of charge.

Persons coming from Montreal or suburban villages, will be carefully questioned as to their residence, whether small-pox has occurred in their families, or whether they have been in contact with the disease.

Inquiries should also be made relative to their baggage, whether it consists of bedding, household goods, etc., likely to be infected, and if any person or article of baggage is considered by the inspector infected, or likely to introduce the disease into this country, they or it should not be permitted to cross the line into the United States.

You may consider persons protected who may show evidence of having had the small-pox or varioloid, or who exhibit a well-defined mark of vaccination.

You may accept as evidence of protection a certificate from any physician in good standing, that the person presenting the

same has been successfully vaccinated. Should you doubt the validity or authenticity of the certificate, you may refuse any such person presenting the same, the privilege of crossing the border unless he will submit to vaccination. Baggage known to have come from any infected district and believed to be infected will be thoroughly fumigated with burning sulphur at the following points, viz.: Rouse's Point, St. Albans, Richford, Newport, and Island Pond.

The collector of customs, of the district of Vermont, representing the Treasury Department, is reported to have stated that it was the intention of the authorities to render the measures of precaution so stringent that not only would there be no chance for the spread of small-pox, but also that there would be no chance even for the fear of contagion on the part of travellers in the vicinity of the frontier. Such a consummation were devoutly to be wished, and such assurances come none too soon to tranquillize the inhabitants of manufacturing towns in Massachusetts, New Hampshire, and elsewhere, so many of whose operatives are in communication with or come from the very class of French Canadians among whom small-pox is now so rife. Recent cases in Fall River, in Haverhill, in Maynard, and other of these manufacturing centres, which were promptly looked after by the local authorities show that protection is urgently needed and that the outer edge of the disease wave has already spread thus far.

We fear, however, that the enthusiastic anticipations of the collector of customs as to the possible stringency of his measures will hardly be realized. Vaccination of suspicious individuals and disinfection of personal effects will do much to limit the labors of the local sanitary authorities in towns and cities exposed to Canadian immigrants, but the utmost vigilance on the part of these authorities will still be needed to guard against the outbreak of epidemics on our side, and their vigor and care should be no whit relaxed on account of the establishment of this inspection on the Canadian border.

On the part of the Central Vermont Railroad, it is said that nothing is being neglected to render travel to and from Montreal as safe as circumstances will permit. No passenger cars coming from Boston or New York, or points intermediate between those cities and St. Albans, are allowed to go beyond that place, the passengers and baggage being transferred to special trains which run only between St. Albans and Montreal.

Dr. Irving A. Watson, Secretary of the New Hampshire State Board of Health, has issued the following circular to local boards without that State's limits:

As many persons coming from Canada over the Central Vermont, Passumpsic and South Eastern and Grand Trunk pass through our State, we have put on medical inspectors for the protection of our large towns and cities against the infection of small-pox. Several railroads pass daily through our State to points in Maine, Massachusetts, Rhode Island and Connecticut. While it is not possible for our State to thoroughly look after persons going into other States, we propose to assist, as far as possible, other health authorities in this work. To this end we will issue an inspector's ticket to all Canadians going over our lines to your city. If desired by you, said ticket will be punched by our inspector so as to give all information obtained of the person as per ticket and key enclosed; thus the enclosed ticket

would indicate that the person came from an infected district, and had baggage. Upon this information your department would at once act knowingly. In addition, if you would pay the cost of a message, we would notify you by telegraph when we found a suspicious case destined for your city. Please inform us at once if you desire inspection tickets issued as above stated.

Such an inspection began last Monday. The Old Colony Railroad Company has agreed to place all passengers from Canada in one car, and the conductors will render all assistance they can to officers who have been detailed to duty at the railroad station. The tickets issued by the New Hampshire authorities will indicate whether the holders have been vaccinated, etc. If a passenger from Canada cannot produce a ticket it will be inferred that he has thrown it away, and he will be quarantined unless he can give a satisfactory account of himself. The boards of health and railroad companies of the neighboring States, acting thus in conjunction, will undoubtedly greatly diminish the risks of the situation.

The riotous proceedings at Montreal have not been renewed since our last issue, but were only restrained by the intervention of the troops and the exercise of rigorous measures of repression; with so ignorant and superstitious a population it will be difficult to enforce systematically the necessary prophylaxis. The hostility shown to Dr. LaRocque in Montreal, and the reported remark of Alderman Gray, chairman of the health committee, that any attempt to carry out compulsory vaccination in Quebec and its suburbs among the French would be repelled by force, show plainly the inability of the authorities and the danger to individuals who attempt to execute their commands, and the vicious ill-feeling of the French toward the English population, indicate that it is necessary that our communities should be prepared for a somewhat prolonged period of possible invasion.

#### THE INDEX CATALOGUE.—VOLUME SIX.

THE sixth volume of this invaluable work which has just appeared, carries the index through *Insfeldt*. With this volume the total number of author-titles reaches 58,885, representing 33,265 volumes and 47,325 pamphlets, 64,142 subject-titles of separate books and pamphlets, and 219,154 titles of articles in periodicals.

The uses which a mere catalogue may subserve beyond the simple record of the presence of the books whose titles are enumerated on the library shelves is exemplified by this volume as fully as by its predecessors. No one can turn these pages without finding many curious and interesting facts recorded. The changes in nomenclature of very ordinary diseases which have taken place in comparatively few years, as shown by the catalogue, are very striking. There are exhibited the synonyms in other languages and also the popular and pedantic names in our own language. Certain authors whose writings have little other value, preserve on their title-pages the popular names of the years in which they wrote. To choose only the English and Latin under *Whooping-cough*, we find not only the spelling *whooping-cough*, but the following titles:

Batter, W. A treatise on the Kinkcough. London, 1773. Knoch, C. L. A. De pncipaliummotetano.

Vienna, 1838. Peirson, A. L. Boylston Prize Essay on Pertusses or chin cough, 1824. Plaz. A. G. De tussi infantum epidemica. Halle Magdeb. 1728. We also find the following terms: Tussini convulsivum. De tussi ferina. Tussi convulsiva infantum.

Hyrtl, the late professor of anatomy, in Vienna, is one of the most voluminous modern writers, or, more correctly, the author of the most numerous separate monographs, the titles of his writings covering three columns. The space occupied by the different editions of Hippocrates exceeds that number of pages, and his commentators occupy fully as much space as the author himself. Hernia, hospitals, hygiene and insanity fill a large portion of the volume.

The United States maintains no national school for medical instruction, nor for any purpose save to train officers for the national defence but it has done work which benefits the whole human brotherhood of physicians in the publication of the medical records of the war, and of this Index Catalogue, as yet uncompleted. One can but feel some anxiety lest the order of the war secretary relating to officers on special duty, the object of which is undoubtedly good, should be so construed as to endanger the future of this great work which reflects so much credit on the nation.

#### MEDICAL NOTES.

—The President has declined to accept the resignation of Surgeon-General Hamilton, of the Marine Hospital Service, which was lately tendered by that gentleman.

—A Washington law firm has sent circulars to retail druggists throughout the country informing them that they have claims against the government, which claims, the firm referred to offer to prosecute without expense to the druggists, for a commission of thirty-three and one-third per cent on the money obtained. It is understood that the claims are for stamps put upon goods before the law requiring them was repealed. The individual claims would range from \$50 upward, the claims of a few of the leading houses probably reaching \$1000. The total amount of the claims is estimated at about \$500,000.

—Mr. Snarry, an English veterinary surgeon, has accomplished a novel feat in the way of surgery. A cow on the Westow Grange Farm, near York, broke its leg, and there being no chance of reducing the fracture, the limb was amputated, and Mr. Snarry tried the experiment of affixing a wooden leg. This has been found to answer admirably, and the cow may be seen grazing, with a calf by its side.

—A writer in the *Therapeutic Gazette* speaks highly of sulphuric-ether inhalations as an expectorant in subacute or chronic bronchitis. He also recommends it to be taken in the following manner: Drop five to ten drops on a lump of sugar, and take every three or four hours.

—The *Medical Times* (Sept. 19) says editorially: "In our opinion, the time has now come for the olivers of past International Medical Congresses to meet together, and decide that, unless the pledge given at Copenhagen is kept, and all attempts to embroil the Congress in ethical disputes are unconditionally given up, the acceptance of the invitation to meet at Washington should be rescinded, and arrangements made to hold the Congress of 1887 in a country where the medical profession possesses greater solidarity."

—A physician recently returned from Montreal, says the public has no idea of the extent of the epidemic of small-pox in that city. He says there are at present at least four thousand cases. The fanaticism of the French-Canadians, evinced by their anti-vaccination riots, which we reported last week, seems to have a strong tinge of race bitterness. They console themselves by the thought that at all events the English are being swept off by the scourge. Even when it was pointed out to one of them that of sixty freshly reported deaths, fifty were of French-Canadians, the reply came — "Well, at least there are ten Englishmen dead."

M. Marey has communicated to the Académie des Sciences his last researches on the locomotion of man and animals. He especially aimed at ascertaining the trajectory or curve described by a portion of a living body in motion. The experimenter formerly used instantaneous photography, but this method he considered to be faulty, because inevitably the curve described was only represented in height and length, both thickness and perspective being neglected. M. Marey now uses stereoscopy. His researches have revealed some interesting facts concerning the act of walking, in the normal state and in lameness, the flight of birds, and the action of the feet of horses.

—Professor Laskowski, of the University of Geneva, who is probably the most successful embalmer in Europe, is reported in the *Lancet* to use an injecting liquid consisting of a mixture of carbolic acid, chloride of zinc, and corrosive sublimate, with the addition of an odoriferous essence. This solution is as clear as crystal, and pleasant to smell. A body skillfully treated by Dr. Laskowski's method assumes "the natural and agreeable expression" it bore immediately after death, and the skin becomes firm and as white as Carrara marble.

—That the science of vital statistics is developing in the Orient is shown by the following anecdote which comes to one of our contemporaries from Berhampore, which is somewhere in the Madras Presidency. It is the duty of the tahsildar (head man of the village) to send in to the collector or head-officer of the district, a periodical return of all diseases, births, marriages, deaths, etc., in his village. In one of these returns the collector discovered there were no births shown, and called upon the tahsildar for an explanation. He replied, "Your Honor will find the births included under the heading 'bowel complaints.'"

—Dr. F. E. Stewart writes in the Philadelphia *Medical Times* (Sept. 19) in favor of the use of coca leaves

in the form of cigars or cigarettes. He concludes that coca smoked seems to produce the same effect on the system as coca taken internally in the form of fluid extract, wine, or elixir, but not in such a marked degree. Coca itself is known to be stimulant, tonic, and restorative to the system in the treatment of various diseases marked by debility and exhaustion. Nervous debility and exhaustion in all its forms, whether caused by diseases or excesses, are said to be relieved by it. Fatigue disappears, to be followed by a feeling of indescribable calm and satisfaction, increased strength of brain and muscle, and desire for mental and muscular occupation.

—According to a Paris correspondent of the Philadelphia *Medical Times*, it was stated in a paper by Dr. Block, "On the State of the Prepuce in Infant Jews," that two operators had made some four thousand seven hundred and ninety-nine circumcisions. They found that they very often had to operate on rudimentary prepuces not covering the gland. In more rare cases (one in five hundred, about) an absence (complete) of the prepuce was found.

—A suggestion which may enhance the value of photography in medical jurisprudence, is that of M. Gosse, for restoring a life-like expression to the eyes of dead bodies. The method consists in placing a few drops of glycerine and water on the cornea.

#### BOSTON.

—The City Council formally inspected on September 30, the new hospital on Deer Island, which has been erected by the city under the supervision of the Board of Directors for Public Institutions. The hospital is of wood and is one story in height except for the reception building which is two stories. There are three wards communicating only by corridors. The appointments are of the best for the comfort of patients, physicians and nurses. The building was opened for patients October 1.

### Whistlelamp.

#### FLATULENT COLIC IN HORSES.

The *American Agriculturist* for July says that when Professor Gamgee was in this country, he said to the writer that more horses died of colic than of any other malady, and he suggested a remedy which has been published in the *American Agriculturist*, and been found efficacious, we doubt not, by thousands of horse owners. The remedy, simply stated, is copious injections of cold or tepid water — that is, cold but not too cold. Water that has the temperature of the air in the summer time is right — say seventy to ninety degrees. The best way to apply it is to use a large funnel, holding about two quarts, to which a rubber tube, three feet long, is attached, and this is terminated by a tin nozzle about fourteen inches long, tapering to a quarter-inch opening. This end should be protected by a lump of solder, so as to prevent injury to the parts. The funnel is filled with water at the level of

the horse's rump, and then lifted up as high as possible. Four to six quarts will usually be sufficient to start the wind; then stand clear. Relief follows at once.

There are many causes of colic, as a sudden change of food, hard work or active exercise after feeding, very rapid eating (as after long fasting and hard work), the chill experienced when exposed to too rapid cooling off after sweating—these are some of the common causes, and are conditions to be avoided at any rate. Care will almost always prevent colic, and the above simple remedy will generally cure it; we have never known it to fail.

#### RECENT RESIGNATIONS FROM THE INTERNATIONAL MEDICAL CONGRESS ORGANIZATION.

The following resignations in addition to those previously published in these columns, are reported: Dr. John C. Dalton, of New York, from the Presidency of the Section of Physiology; Dr. R. B. Maury, of Memphis, the Vice-Presidency of the Section of Gynecology; Dr. Thomas F. Rochester, of Buffalo, the Vice-Presidency of the Section of Medicine; Dr. E. Fletcher Ingalls, of Chicago, the Secretaryship of the Section of Laryngology; President Gilman, of Johns Hopkins University, the Councilorship in the Section of Medical Education, Legislation, and Registration; Dr. Thomas T. Sabine, of New York, the Councilorship in the Section of Anatomy; Dr. Thomas M. Markoe, of New York, the Councilorship in the Section of Surgery; and Dr. E. G. Loring, of New York, the Councilorship in the Section of Ophthalmology; Dr. William H. Welch, of Johns Hopkins University, from the Secretaryship of the Section of Pathology; Dr. T. A. McGraw, of Detroit, and J. R. West, of Richmond, Indiana, Councilorships in the Section of Surgery; Dr. E. H. Hazen, of Davenport, Iowa, the Councilorship in the Section of Otolaryngology; and Dr. E. L. Shurley, of Detroit, Mich., a Councilorship in the Section of Laryngology.

#### DEATH OF DR. PAUL BÖRNER.

The death of Dr. Paul Börner at the age of fifty-six, after a brief illness, is reported. He was widely known as the editor of the *Deutsche Medicinische Wochenschrift*.

#### CHRONIC ALCOHOLISM.

According to the *British Medical Journal*, Messrs. Dujardin-Beaumetz and Audigé have communicated to the Institute the result of their researches on chronic alcoholism. From June, 1879 to July, 1883, eighteen pigs were experimented upon, each of them with a different sort of alcohol, such as ethylic and methylic alcohol, alcohol prepared from corn, beet-root, and potatoes (pure and impure), absinthe, and tincture of absinthium. These were given daily with the food, in the dose of one to one and a half grams of alcohol, two gram of absinthe, and two centigrams of tinctura absinthii for one kilogram of the weight of the body. The symptoms of intoxication by alcohol were sleepiness and prostration, vomiting of bile and glairy mucus, diarrhoea, and sometimes intestinal hæmorrhage, dyspœnia, tremor, and incomplete paralysis of the hind

legs. Some animals which were killed or died during the experiment were examined by Professor Cornil. He found congestion of the digestive tube, sometimes causing hæmorrhage; congestion and inflammation of the liver, but without cirrhosis; congestion of the lungs; and, finally, atheroma of the large blood-vessels, especially the aorta. The animals were not emaciated, but presented numerous extravasations of blood into the subcutaneous and muscular tissues. Impure alcohol had a much more rapid and deleterious influence than rectified alcohol. The symptoms caused by absinthe and tinctura absinthii were excitement, and spasmodic contractions of the muscles and cutaneous hyperesthesia, but true epilepsy was never noticed.

#### THE DISPOSAL OF LONDON'S SEWAGE.

The city of London has reached a point in the development of its sewerage system where it finds it impossible longer to discharge its sewage unchanged into the Thames. Two plans are now, therefore, under consideration, as we learn from the *Medical Times* (September 19). Of these the first is that of Sir Joseph Bazalgette, the official adviser to the Metropolitan Board of Works. He proposes to carry the sewage from the southern outfall under the Thames by means of a huge siphon to a point near Rainham, and thence to convey the sewage of both north and south London in a culvert nearly twenty miles in length to Thames Haven, where, after some sort of depuration, it would be pumped into the river, which here has become an arm of the sea. The objection to this plan is, that in order to produce an effluent of sufficient purity nothing would avail but chemical treatment, this one is out of the question on account of its cost and the impossibility of disposing of the enormous quantity of so-called native guano that would be produced. The action of sea-water on sewage, coagulating the albuminoid matters and transforming the sulphates into sulphides, would lead to consequences scarcely, if at all, less grave than exist at present, and the Local Board of Southend would justly resent the pollution of the waters in their immediate proximity.

Mr. Bailey Denton and Colonel A. S. Jones have proposed a scheme, which, bold as it may appear, is considered by our contemporaries to be quite feasible. It is to convert the Island of Canvey into a vast sewage farm. This island has an area of 5,000 acres of low alluvial land reclaimed from the sea. Its surface is ten feet below high water mark, but it is protected by a sea wall fourteen feet high. Leaving a zone of a mile in width on the northern side of the island, or that adjoining the Essex coast, on which the necessary buildings would be erected, they would divide the rest of the area, about 4,000 acres, into a series of irrigation fields and filter beds, in which the sewage, brought by the culvert proposed by Sir Joseph, would be pumped, and there treated by precipitation and downward intermittent filtration. As Canvey Island is only a mile further eastwards than Thames Haven, a very slight extension of the culvert would be required. It is claimed that the effluent resulting from the proposed method of treatment would not have the slightest deteriorating effect on the sea-water, being in fact far purer than the water of the Medway and other rivers flowing into the Thames. At Merthyr Tydfil it has been shown to contain but .012 of organic nitrogen and .025 parts of ammonia in 100,000 parts, a

composition little removed from that of potable waters. Even now a slimy mud lines the sea-shore at Leigh and Southend, and it is in the highest degree probable that Sir J. Bazalgette's scheme would ruin these towns as health resorts, and be most detrimental to the fisheries. From these objections Mr. Denton's scheme is free, and the additional cost would be insignificant. The island could be acquired by a rate on the metropolis of three farthings in the pound, and the work of buying out the 300 inhabitants who are now saddled with a rate of 13s. 4d. in the pound for the repair of their sea-wall could not be very expensive. It is calculated that the island would suffice for the treatment of the entire sewage of the metropolis for a hundred years, by which time the accumulated sludge would have raised the level of its surface to that of the sea-wall. And then—if there is need to speculate as to so remote a future—it might revert to agriculture, and perhaps a new Canvey be reclaimed from the sea, or the scene of operations be removed to the boundless flats of Foulness.

#### CEREBRO-SPINAL MENINGITIS IN A ROLLER-SKATER.

At a recent meeting of the Brooklyn Pathological Society (New York *Medical Journal*, September 26), Dr. George W. Cushing reported the following case. He said that, about midnight of March 11, 1885, he had been called to see the patient (J. C.), who was twenty-eight years old and of fine muscular development. He was restless, with a hot, dry skin, the pulse 135, the temperature 104° F., the respiration labored, headache, and the pupils contracted and intolerant of light. He also had marked pharyngitis and bronchial congestion. He was averse to talking and to being disturbed. A febrifuge mixture was ordered, also bromide of potassium. Subsequently the man's wife gave the following history: Her husband had been engaged in a roller-skating match at the Madison Square Garden the week before, ending at midnight March 7th. He was at home the next day (Sunday), and rested a part of the time, but was unable to eat, and seemed very much exhausted. He went to New York on Monday, for the purpose of getting the money due him from the proceeds of the contest, and did not return until Tuesday, when he had symptoms of an ordinary "cold." The patient's surroundings were so poor that it was impracticable for all the speaker's directions to be carried out, and, when he called the next morning, he found that stupor was gradually setting in. There were urinary incontinence and spontaneous bloody evacuations from the bowels; there was also great difficulty in taking food and medicines, and the head was rigidly drawn back. The ankles and feet were swollen and chafed from the pressure of the skates. Cerebro-spinal meningitis was diagnosed, and counter-irritants were applied to the spine and the back of the head, with cold to the top of the head. He continued to grow worse until the 15th, when the speaker was called in haste, and found him dead—he had probably been dead for several hours. The autopsy confirmed the diagnosis, the case having been placed in the Coroner's hands as a matter of public interest in connection with the present furor in regard to roller-skating.

The following condition of the brain and the cord was demonstrated:—

The dura mater of the brain and cord presented nothing abnormal. The pia mater, however, was yellow, and about 3 mm. thick over the anterior half of the cerebral convexity on either side. All over this area, the convolutions, including the upper two temporo-sphenoidal convolutions, were hidden from sight; but over the posterior half of the convexity the convolutions were distinctly discernible, and only the sulci were filled with pus. The inferior, or orbital, surfaces of the frontal lobes were deeply injected, but not purulent. The yellow thickening of the pia was also noticeable in the anterior half of the great median fissure of the brain, and extended half-way down to the corpus callosum. This purulent condition of the pia extended to the base of the brain, along the Sylvian fissure, to the interpeduncular space, where the same suppurative condition of the pia was noticeable. That covering the pons and surrounding the medulla was affected in like manner. The intra-meningeal space of the cord was filled with pus to such an extent as to distend the dura, and well up in the incision made into the membrane in the lower part of the vertebral canal, preparatory to extracting the cord. The pia, throughout the whole length of the cord, was thick and yellow, while the cord itself was softened throughout its whole extent below the cervical enlargement. It was also sclerosed on the left side in the upper thoracic region, the white portion being principally affected.

In regard to the aetiology of the case, Dr. Leuf would differ with those gentlemen who would attribute the man's death to a healthful and beneficial exercise. That the prolonged mental and physical strain to which he had necessarily been subjected, together with the known privation and exposure, were important factors bringing about the termination of the disease, no one could or would deny; yet it was wrong, he thought, to consider them the causes of the trouble. When we reflected how little there was in the way of precedent for such a supposition, in the face of extremely prolonged and excessive walking, running, rowing, swimming, and the like, it was fairer and more rational to infer that this meningeal inflammation had been brought about by a pre-existing cause. Still, the case might accomplish much good by checking the rage for roller-skating, although it was desirable that as many persons as possible should avail themselves of this graceful and harmless exercise within proper limits. Probably it should not be indulged in much more than half an hour at any one time. It was interesting to inquire how much work the craze was likely to bring to gynaecologists and to specialists in diseases of the chest, and perhaps to neurologists.

#### Correspondence.

##### INTRODUCTION OF ANIMAL VACCINATION INTO AMERICA BY DR. MARTIN.

MR. EDITOR.—I desire to submit the following correspondence to the candid consideration of my brethren of the regular profession:

27 Dudley St., Sept. 19, 1885.

THOMAS WATERMAN, M.D.

Dear Sir.—My attention has just been called to an article in the *Boston Post* of September 15th, in which the statement appears that in 1867, you and Dr. Garreau imported animal vaccine virus from Berlin, vaccinated a series of calves, and, during the small pox epidemic of that

year supplied the citizens of Boston with from 18,000 to 20,000 points, and that several years after, Dr. Martin, of Roxbury, followed in your wake. As the claim of my father, Dr. Henry A. Martin, of having first introduced the practice of true animal vaccination into this country has never before been questioned, and has been universally recognized, and as the above statement has never appeared before, I must beg to ask you if it is possible that you yourself make such a claim. If you do, I will esteem it a favor if you would have the kindness to furnish me with data tending to support it. An early reply would greatly oblige.

Yours very truly, STEPHEN C. MARTIN, M.D.

146 Boylston St., Boston, Sept. 22, 1885.

DR. S. C. MARTIN :—

Dear Sir,—My attention has also been called to the article in the *Post*, to which you allude. I know nothing whatever about the authorship of the article nor the source from which the writer obtained his information.

Very truly yours, THOMAS WATERMAN.

27 Dudley St., Sept. 23, 1885.

DR. THOMAS WATERMAN :—

Dear Sir,—Pardon me for saying that your letter does not answer my inquiry. Of course I knew who the immediate author of the statement referred to was, and the animus in making it. My inquiry is, did you and Dr. Garceau, or did you individually, before 1870, introduce into this country and practise true animal vaccination, that is, the inoculation of a series of animals of the bovine species with heter-transmitted vaccine virus, derived from a spontaneous case of cow-pox, and by this means successfully continue the production of true animal vaccine virus, for the vaccination of the human species? As that statement in substance has been made in the public press within a few days, and as I am not aware that you personally or Dr. Garceau ever made such claim, it seems fair that you should either deny such statement, or distinctly make the claim referred to. I shall feel obliged for a direct answer to my question.

Yours very truly,

STEPHEN C. MARTIN.

146 Boylston St., Boston, Sept. 24, 1885.

DR. S. C. MARTIN :—

Dear Sir,—It seems to me that our correspondence is entirely gratuitous and unnecessary. I have already written you that I know nothing of the authorship of the article alluded to. I will further say that I have furnished no material for it to any person whatever. When you can show that I have made any such claim as you hint at, it will be time enough for me to show you on what grounds I base the claims.

Very truly yours,

THOMAS WATERMAN.

It appeared useless to write further to Dr. Waterman, so on September 24th, I sent the following letter to Dr. Garceau :—

27 Dudley St., Sept. 24, 1885.

T. GARCEAU, M.D. :—

Dear Sir,—In an article on Vaccine Virus in the *Boston Post* of Sept. 15, 1885, it is stated in substance that you and Dr. Waterman, of Boston, in 1867, introduced into Boston and for some two years successfully practised true animal vaccination, and that Dr. Martin "followed in your wake." I am not aware that the claim of my father, the late Dr. Henry A. Martin, of having inaugurated the practice of true animal vaccination in this country has ever before been questioned. Please inform me: (1) Whether you authorized the above statement made by the *Post*. (2) Whether such statement is true, and if so, in justice to all concerned, furnish me data to support it, and oblige.

Yours respectfully, S. C. MARTIN.

In reply I received the following from Dr. Garceau's son :—

22 Highland St., Sept. 25, 1885.

S. C. MARTIN, Esq. :—

Dear Sir,—Your note of the 24th at hand. My father

is at present out of town and will return in a few days. I will give him your note on his return, and doubtless he will reply.

Yours respectfully,

EDGAR GARCEAU.

Dr. Garceau returned to Roxbury on the morning of September 27th. I have received no reply from him.

The statement referred to in the above correspondence was made to the *Post* reporter by one Dr. William C. Cutler, of Chelsea, Mass. His claim to the title M.D. rests on a diploma of an institution, now defunct, called the Hygieo-Therapeutic College. Among its distinguished faculty whose names are appended to this diploma, is a Professor of Phrenology, and also one of "Materly Therapy," whatever the latter may be. Those curious as to the status of the diplomas of this institution are referred to the Fourth Annual Report of the State Board of Health of Illinois, pp. 44, 95. Dr. Cutler propagated vaccine virus under the name of the New England Vaccine Company, which, according to his own sworn statement, is not an incorporated company or partnership, and has no president or other officers. He advertises himself as its president. The other two gentlemen are members of the regular profession, and are Dr. Cutler's selling agents. The article containing the statement is an elaborate puff of Dr. Cutler's establishment, and is being used to further the interests of the business. It will be observed that Dr. Waterman fails to answer my inquiry, and puts me to the legal proof of the very question I ask him, and Dr. Garceau entirely ignores my letter. I am aware that a frank and open denial by these gentlemen of the statement made by their business principal, would put the latter in an awkward position; but I cannot allow the business arrangements of these three gentlemen to compromise, however slightly, the well-earned honors of my father, for his labors in the cause of vaccination. I here distinctly assert that true animal vaccination, as defined in my second letter to Dr. Waterman, was first introduced into this country by my father, the late Dr. Henry A. Martin, in September, 1870. If these gentlemen claim otherwise, I call upon them to do so in your columns, and to produce proofs substantiating their pretensions. No sound of such claim was ever heard before my father's death in December last. "When a strong man armed keepeth his palace, his goods are in peace."

Very respectfully,

STEPHEN C. MARTIN, M.D.

27 Dudley St., Roxbury, Oct. 3, 1885.

## REQUEST TO OCULISTS AND PUBLISHERS OF OPHTHALMOLOGICAL WORKS.

MR. EDITOR.—Having taken charge of reporting for the "Revue Générale d'Ophthalmologie," edited by Dr. E. Meyer of Paris and Dr. Dor of Lyon, on the progress of ophthalmology in our country, I beg leave to request all authors and publishers of ophthalmic works and papers, to send me copies or reprints of their respective publications in order to enable me to give the most complete review of the current ophthalmic literature of our country in a periodical of the largest circulation among our profession. (Medical papers please copy.)

DR. M. LANDESBURG.

10 W. 34th Street, New York, October 3, 1885.

## APPEAL FOR EMBRYOLOGICAL MATERIAL.

MR. EDITOR.—May I again appeal through your valuable columns to the practising physicians who may obtain human ova or fetuses in the course of their professional occupations, and who do not require the same for their own studies, to consider my own very great need of additional specimens, to enable me to satisfactorily complete the treatise on human embryology upon which I am engaged. I still desire to obtain a considerable additional number of all ages; the generous assistance I have already received,

leads me to hope for continued kindness. I need hardly add that I shall be only too glad to meet any expenses incurred in my behalf.

Specimens are of course most valuable when they are received a few hours after delivery. When it is not possible to send them fresh it is best to place them in sixty per cent alcohol, unless it is feasible to adopt some of the other more perfect but also more elaborate methods of preservation.

It is also desirable to direct attention especially to the extreme scientific importance of securing very young ova, that is, under twenty days. Impregnation appears to occur at the first menstruation omitted. When a patient who has been menstruating regularly omits a period, and pregnancy is indicated, it is not rare that five to twenty days later a hemorrhage occurs, and such discharges are often accompanied by the ovum. The ovum at ten days is a vesicle about an eighth or sixth of an inch in diameter, of a pale flesh color, and having a few short villi. Up to the twenty

days it enlarges rapidly and the villi of the chorion become longer and branched. Every such specimen ought to be preserved with the utmost care; it should on no account be opened, nor submerged in water. Such young ova may be preserved by placing them in alcohol of sixty per cent for twenty-four hours and then in alcohol of seventy per cent, or better still, place them first for three minutes in a mixture of one part concentrated nitric acid with nine parts of water; then in sixty per cent alcohol for a day, and finally in seventy per cent for permanent keeping.

A thorough study of even a single human ovum under three weeks would be of the utmost interest to science. There is no satisfactory description of any ovum under fourteen days. We must therefore earnestly hope that the opportunity to secure such precious material will be seized by whomever it comes to. I have the honor to remain

Yours faithfully,

CHARLES SEDGWICK MINOT.

Harvard Medical School, Boston, October 3, 1885.

Deaths reported 1,723; under five years of age 678; principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrheal diseases) 413, consumption 256, lung diseases 121, diarrheal diseases 173, typhoid fever 63, diphtheria and croup 97, malarial fevers 27, whooping-cough 22, cerebro-spinal meningitis five, scarlet fever 16, erysipelas three, measles three, puerperal fever three, small-pox one. From malarial fever, New Orleans 10, New York six, Baltimore five, Chicago, District of Columbia and New Haven two each. From whooping-cough, New York 14, Baltimore five, Chicago, District of Columbia and Providence one each. From scarlet fever, Chicago five, Boston three, Fitchburg, two, New York, Baltimore, Fall River, Cambridge, Springfield and Salem one each. From cerebro-spinal meningitis, New York, three, Boston and Worcester one each. From Boston two, measles, New York one. From puerperal fever, New Orleans two, District of Columbia one. From erysipelas,

New York, Boston and Providence one each. From small-pox, New York one. The case of small-pox reported in Lowell.

In 116 cities and towns of Massachusetts, with an estimated population of 1,440,921, (estimated population of the State 1,955,101), the total death-rate for the week was 15.05 against 17.76 and 18.16 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,905,116, the death-rate was 17.3. Deaths reported 2,570; infants under one year of age 897, acute diseases of the respiratory organs (London) 174, diphtheria 235, whooping-cough 67, measles 56, scarlet fever 15, fever 42, diphtheria 31, small-pox (London three, Bristol one), four.

The death-rates ranged from 12.3 in Brighton to 27.5 in Preston; Birkenhead 20.7, Birmingham 16.1, Bradford 11.1; Hull 12.6; Leeds 18.0, Leicester 15.3; Liverpool 23.2, London 15.6; Manchester 24.2; Nottingham 15.5; Sheffield 18.1.

In Edinburgh 12.9; Dublin 20.7; Glasgow 26.7.

The meteorological record for week ending September 26th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole of the United States Signal Corps:—

Week ending	Barometer.		Thermometer.				Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM SEPTEMBER 26, 1885, TO OCTOBER 2, 1885.

MCPARLIN, T. A., colonel and surgeon. Directed to transfer his duties and the public funds, for which he is accountable, as assistant medical purveyor, to Captain Henry Johnson, medical storekeeper, who will, in addition to his present duties, temporarily perform the duties of assistant medical purveyor, New York City. S. O. 223, A. G. O., September 29, 1885.

CALDWELL, D. G., major and surgeon. Ordered from Fort Laramie, Wyo., to Fort D. A. Russell, Wyo. S. O. 97, Department of Platte, September 28, 1885.

ADAIR, G. W., captain and assistant surgeon. Granted leave of absence for one month with permission to apply for one month's extension. S. O. 104, Department of Dakota, September 18, 1885.

BOUCHEMIN, LOUIS, captain and assistant surgeon. Ordered from Fort D. A. Russell, Wyo., to Fort Laramie, Wyo. S. O. 97, Department of Platte, September 28, 1885.

BUCHNELL, GEO. E., first lieutenant and assistant surgeon. Ordered from Department of Dakota to Department East. S. O. 219, A. G. O., September 24, 1885.

MACATELEY, C. N. B., first lieutenant and assistant surgeon. Relieved from duty at Fort A. Lincoln, D. T., and ordered for duty at Camp Poplar River, M. T.

KINDLER, WM. L., first lieutenant and assistant surgeon. When relieved from duty at Camp Poplar River, M. T., by Assistant Surgeon Macateley, to report to commanding officer, Fort Snelling, Minn., for duty. S. O. 105, Department of Dakota, September 21, 1885.

WALES, P. G., first lieutenant and assistant surgeon. Relieved from temporary duty at Boise Barracks, and ordered for duty at Fort Conr d'Alene, Idaho. S. O. 100, Department of Colorado, September 21, 1885.

EWING, C. B., first lieutenant and assistant surgeon. Relieved from duty at Fort Stanton, N.M., and ordered for duty at Fort Leavenworth, Kans. S. O. 117, Department of Missouri, September 25, 1885.

#### OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING OCTOBER 3, 1885.

JONES, WILLIAM H., surgeon. To navy yard, League Island, Pa., October 15th, as the relief of Medical Inspector M. Bradley.

BRADLEY, MICHAEL, medical inspector. Detached from navy yard, League Island, Pa., October 15th, and placed on waiting orders.

OWENS, THOMAS, assistant surgeon. To naval station, New London, Conn., as the relief of Surgeon Wm. A. Corwin.

CORWIN, WM. A., surgeon. Detached from naval station, New London, Conn., and ordered to the United States Steamship "Adams," October 31st.

MCARDLE, A. F., surgeon. Ordered to the United States Steamship "Vantie," without delay, as the relief of Surgeon H. J. Law.

LAW, H. J., surgeon, detached from the United States Steamship "Vantie" and wait orders.

STIMOS, W. J., surgeon. Detached from the naval academy, October 1st, and wait orders.

DRENNAN, M. C., surgeon. Detached from the naval academy, October 1st, and wait orders.

CABELL, ARTHUR G., passed assistant surgeon. To the United States Steamship "Adams," October 31st.

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE FOR THE WEEK ENDING SEPTEMBER 26, 1885.

AUSTIN, H. W., surgeon. To proceed to Burlington, Vermont, on special duty. September 23, 1885.

#### SOCIETY NOTICES.

MIDDLESEX SOUTH DISTRICT MEDICAL SOCIETY. — The Semi-Annual Meeting of the Middlesex South District Medical Society will be held at Porter's Hotel, North Cambridge, on Wednesday, October 14, 1885, at 12 o'clock. Essays will be presented by Drs. Cutler of Waltham and Hildreth of Cambridge. The Censors of the Society will meet at the same place at 11 A.M. of the same day to consider applications for admission to the Massachusetts Medical Society. You are requested to notify the Secretary by return mail if you will be present at a dinner which will be had at 2 P.M. provided that twenty-five members assent thereto. Telephone number of Hotel is 7294.

WALTER ELA, Secretary.

CAMBRIDGE, October 6, 1885.

MASSACHUSETTS MEDICAL SOCIETY. SUFFOLK DISTRICT. — Section for Clinical Medicine, Pathology and Hygiene. The approaching meeting commences the eighteenth year of the Section. In this time, and especially during the more recent years, a large amount of valuable work, of varied character has been accomplished. An especial feature of the Section, aside from its strictly medical work, has been the presentation of many matters of general and public interest, among which may be mentioned the subjects of Metropolitan Sewerage, Milk Supply, Public Sanitation, Purity of Drugs, Domestic Hygiene, Epidemic Diseases, the Water Supply of Boston, etc., in which gentlemen from other professions often took part by contribution or discussion, and the general public manifested a lively interest. The meetings have been largely attended, and the papers and discussions have been regularly and promptly published in two of the leading Medical Journals of the United States. It is hoped that the coming year may be productive of equally profitable results, and to this end your hearty cooperation is earnestly solicited. Please send the titles of any papers or communications you may desire to present, at as early a date as possible, to:

ALBERT N. BLODGETT, Secretary.

The Section will meet at 19 Boylston Place, on Wednesday, Oct. 11, at 7.15 o'clock. Dr. C. F. Folsom will present "A Case of General Paralysis," Dr. P. C. Knapp will exhibit "A Case of Pseudo-Hypertrophic Muscular Paralysis," Dr. F. L. Knight will speak on "Recent Methods of Treating Hay-Fever."

#### BOOKS AND PAMPHLETS RECEIVED.

Address of the State Board of Health and Vital Statistics of the Commonwealth of Pennsylvania. To the People of Pennsylvania. Harrisburg, 1885.

State Board of Health Bulletin. For the Month Ending July 31, 1885. Vol. I. No. 1.

Announcement 1885-86 of the Missouri Dental College. St. Louis, Mo. Twentieth Session.

HEREDITARY OR DEGENERATIVE ATAXIA. SIX CASES IN ONE FAMILY.—DEATH OF ONE CASE, AND AUTOPSY.<sup>1</sup>

BY W. EVERETT SMITH, M.D., FRAMINGHAM, MASS.

"Diese Befunde sind vielleicht im Stande ein Licht auf die Entstehungsweise der hereditären Nervenkrankheiten zu werfen. Diese treten unter den Begriff der Bildungsheimmungen."  
Möbius: Ueber die hereditäre Ataxie.

**FAMILY HISTORY:** The patients to be considered in this paper are J. W. W. (father), Emma, Alice, Clara, Jessie, and Myra (daughters). There have been thirteen children in the family, eight girls and five boys. Two of the girls died years ago unmarried; one at the age of sixteen from acute meningitis, the result of injury, the other (Alice) at the age of twenty-five, with symptoms, so far as I can ascertain, exactly like the symptoms I shall describe in her sisters. I never knew them. One daughter left home at the age of fourteen. She is married and has always been strong and healthy, but has an anemic child about twelve years old, who for years has been obliged to wear a mechanical support upon one of her ankles. The remaining five daughters are unmarried and have always lived with their parents. Their ages, when I first met them in October, 1882, were thirty-seven, twenty-nine, twenty-seven, fifteen and fourteen respectively. At this time the oldest son was thirty-five (married and the father of young and anæmic children), and the youngest son seventeen; all the sons were well developed, strong and healthy, except possibly the oldest, who in 1881 cut his foot with an axe and barely escaped death from tetanus; since then he has never been well.

The family upon both the father's and mother's side is long-lived and healthy, with no history of consanguineous marriages, insanity, syphilis, or any inherited disease that I can ascertain by the most careful inquiry. The family of Mr. W. is, however, peculiarly nervous and excitable and has a marked history of drunkenness in the two previous generations: his father may possibly have had ataxic symptoms before his death, although the history is not quite clear; his mother had the rickets when a girl and was of a very quarrelsome disposition in the latter years of her life, while he has a brother who lacks all moral sense and is now serving a long sentence in the State Prison for aggravated assault. None of the present generation have ever used liquor of any kind, either habitually or to excess.

In the family of the mother, too, there is an instance of some undetermined nervous peculiarity. A niece, now twenty-one, has for the last ten years been able to walk only by the aid of a mechanical support upon the right ankle, while for the last five years she has been practically without the use of the right wrist and hand from some unaccountable weakness which invaded them insidiously and without assignable cause.

The boys, as I have said, are and always have been well. When, however, the girls have reached the age of six or seven, they all, with three exceptions—the one who died from meningitis, the married one and the youngest, who is now (June, 1885), aged sixteen—have developed a series of morbid symptoms

regular in order and progression. The first symptoms noticed by them have been gastric disturbances and palpitation of the heart, followed by an unsteady gait which later became purely ataxic. This ataxia gradually extends to the hands; and here the disease seems to remain stationary for an indefinite period of time. I will describe the cases as I saw them in October, 1882.

**Clinical History:** CASE I. Emma, aged thirty-seven, when a child was bright and quick at figures. At about the age of six she began to manifest a weakness in the lower limbs and an ataxic gait. Of earlier symptoms no definite record can be obtained from her, since she is tongue-tied, has lost the power of articulation and can utter only a sort of guttural laugh. The general history of the case, however, is pretty clear. The muscular weakness gradually invaded the upper extremities causing a "wrist drop," and an incoordination of movement in the hands. At about the same time, or a little later, her younger sister, Alice, began to develop similar ataxic symptoms and complain of muscular weakness.

Upon analysis of the drinking-water made at this time (1862) by Dr. Geo. Rice, of Framingham, and Dr. Hayes, of Boston, lead was detected in considerable amount. The urine was not examined. In deter-

ence to medical opinion the lead pipe then used to convey the water from the well was at once removed. Gutta-percha pipe was put in its place but proving unsatisfactory was soon superseded by earthenware pipe. In 1874 the well itself was abandoned and the supply of water has since been brought in tin-lined pipes from a new spring upon a distant hill. This water I have carefully analyzed but can find no lead in it. Nor have I ever been able to find lead in the urine of any member of the family.

In spite, however, of all precautions the ataxic

<sup>1</sup> Read by invitation, before the Section for Clinical Medicine, Pathology, and Hygiene, Suffolk District Medical Society, June 2, 1885.

symptoms not only continued to increase but even attacked new patients (always the girls) in the family, some of whom had never used the suspected water from the old well. Alice died in 1871. Before her death she had suffered greatly from gastric and abdominal pain. Her final illness was about three weeks in duration and was characterized by spinal pain and by muscular spasms and contractures. She died in convulsions. I never knew her.

Emma, a helpless creature, still lives and sits or half reclines in a large chair most of the time. She has an excessive right lateral curvature of the spine combined with cyphosis, her feet are enlarged and fixed immovably in the position of equino-varus, even the slightest passive movement at the ankle-joint being no longer possible, the hands are flexed upon the forearm and the head rests helplessly upon the chest. Her position is perfectly shown in the accompanying photographs.<sup>2</sup> There is complete paralysis of the

lower limbs and only the slightest possible voluntary but still wholly incoordinate movement of the hands. She can neither pick up objects from her lap nor hold them when placed in her hand. Her legs often jerk involuntarily.

Electro sensibility is greatly decreased. Electro irritability, as tested with the faradic current is decreased, but increased even to spasms with the galvanic (5 cells, Stohrer). The left side of the body is less responsive than the right and the lower extremities less than the upper to electrical stimuli. The tendon reflexes are wholly absent but the *plantar reflex is present* and she has never had any girdle sensation. The cutaneous circulation is low and the feet and ankles

are usually purple with congestion. There is a partial facial paralysis so that saliva constantly flows from the mouth. The muscles of deglutition are so impaired in their action that it is impossible for her to masticate food and almost impossible for her to swallow either food or drink. There is no atrophy of the optic disk; no paralysis of sphincters of rectum or bladder and no tendency to bed sores.

For the past fifteen years she has been subject to frequent epileptic attacks and to painful muscular spasms and contractures in the lower extremities. She is irritable at times, becomes much excited if her desires are not immediately comprehended and will often shout for hours for no apparent reason. She takes note of her surroundings and is keenly sensitive to comments that are made upon her; gives considerable evidence of intelligence and attempts to read the papers, calling attention to items that particularly interest her.

In May, 1885, I re-examined her and find that although it has been nearly a year since she has had an epileptic convulsion she has for six months been markedly losing strength. She no longer cares to read, is suffering from palpitation of the heart and gastric trouble, begins to complain of considerable pain and shows an increasing prostration. She represents the completest development of the disease as it has occurred in this series of cases.

CASE III. Clara, aged twenty-nine, had seemed to her parents a child of ordinary health until she reached the age of nine or ten, when she began to complain at times of palpitation of the heart, of dyspnea and of muscular weakness in the lower limbs. When she was sixteen she had what was called a "gastric fever." She did not remember that she had ever had any colic pains or fleeting pains in the joints, but had suffered greatly from acidity of stomach and nausea.

Soon after these initiatory symptoms of palpitation and muscular weakness, she began to notice that she had the same peculiar gait that she had seen in her sisters, Emma and Alice, and *later* the same incoördination of movement in her arms and hands. This was about 1869. Soon walking upstairs became almost impossible from inability to raise the feet high enough. About eight years ago she had a sickness marked by headache and pain along the spine; was delirious for nearly a fortnight. Since that time she has been duller than before and more inclined to doze and sleep.

When first I saw her in October, 1882, she was in a prostrated condition without fever. Pulse 140, but scarcely to be detected at the wrist. Dyspnea excessive. She complained of lassitude, headache and nausea, of a burning heat in the legs, and of a girdle sensation that seemed like a band of about a hant's breadth becoming tighter and tighter around her. This state of prostration lasted about a week, at the end of which time I could make a more careful study of the case. She was very anemic and had right lateral curvature of the spine together with cyphosis. She complained of vertigo, and of a dull, heavy feeling at the base of the skull. There was almost complete paresis of the lower extremities, both feet were in position of equino-varus and ankles as immovable as though ankylized. The muscles of the thighs and calves of legs had become so contracted that the lower limbs were much distorted. Her photograph would have looked not unlike the photographs of her sister Emma.

<sup>2</sup> The photographs are true to life in showing the peculiar "chopped-off" appearance of the toes and the marked enlargement of the feet. This is not the fault of perspective.

In the upper extremities, the muscles of the hand, and especially the ball of the thumb, did not seem so wasted as did other parts of the muscular system. Has had a "wrist drop" for a number of years, although she could easily raise the hand upon the wrist and supinate it. She could raise the arm only slightly and with the greatest difficulty; could not raise it level with the shoulder. The muscles of the trunk had so far lost their power that she could not sit securely in her chair, but "slouched down" and tended constantly to slip out; she then had not the power to lift herself back into place.

There was no facial paralysis and she could protrude the tongue normally. Deglutition, however, was often extremely difficult and a well-marked tremor of the head was called forth by attempts at voluntary movements. There was a marked peculiarity in her speech, the voice often degenerated into a mere whisper and the words came always slowly and rhythmically like the "scanning speech" of multiple sclerosis. The simplest mental acts were the result of laborious effort; there was always a tardy response to questions because she required time to comprehend one's meaning clearly and memory had become exceedingly defective.

The vitality of the skin, especially in the lower extremities, was very feeble and feet and ankles were markedly congested. She complained greatly of "chilblains." The skin in the beginning of her disease used to be hyperæsthetic, but for six years had been growing anæsthetic, so that she now could scarcely distinguish whether I was pinching, pricking, tickling, or merely rubbing the skin with the ends of my fingers. When, however, she had recognized that her skin was touched, a mental process requiring usually several seconds of time, she said she felt the contact more keenly than she used to feel it and that the sensation lasted longer than it used to last. Sometimes the slightest impression would cause local muscular spasms. Frequently when sitting, but especially in bed, the legs would jerk and flex so powerfully that she would beg to have weights put upon the knees to keep them down. Tendon reflexes entirely absent; no ankle clonus. She often had the sense of formication in the trunk and lower extremities and of a tingling in the ends of the fingers. Her hearing had become very defective and vision was confused. In watching a carriage pass the window she said she could not distinguish between the front and the hind wheels; the front wheels seemed to be where the hind wheels ought to be, but where the hind wheels were she could not tell. There was a marked chromatic aberration and also nystagmus. No strabismus. Muscular volitions were almost constantly seen and caused her great annoyance. The pupils seemed normal in size and reaction to light. There was no atrophy of the optic disk that I could distinguish by an ophthalmoscopic examination.

After securing a generous diet and various tonic remedies, I attempted, in December, 1882, to relieve in some measure the contractures in the lower extremities. Another attack of collapse, however, interfered for a time with any active treatment. Later I began to apply electricity and was surprised to note the rapid increase of strength in the back and lower limbs. In January, 1883, I applied a plaster jacket temporarily to the trunk and thereby gave the muscles of the back so much support that she regained the power of raising herself from the chair without assistance, and

of standing upon her feet. A little later I applied silicate bandages to the feet and gradually got the ankle-joints flexible and the feet in fair position. She could now move them readily and even raise them from the floor so that she succeeded in walking a few steps with the aid of her mother.

Among the many varieties of tonic treatment that I tried I will especially mention phosphorus, the phosphide of zinc, strychnia, and the nitrate of silver, finding the silver to yield the best results and giving it in half-grain doses three times a day. Strychnia could not be long continued since the most minute doses quickly produced tetanic spasms and great distress.

Under such care as I have thus briefly outlined, and with the exception of several attacks of dyspnoea, vomiting, and collapse, the patient enjoyed a better degree of health until August, 1883, than she had had for years. She now began to suffer the most intense and agonizing pain along the entire tract of the right sciatic nerve from the lumbar region of the spine to the extremities of the toes. Speedily the symptoms of acute myelitis in the cervical and upper dorsal region were noticed, accompanied at times with a decided tendency to opisthotonos. Another collapse ensued marked by an utter rejection of food and by vomiting independent of the taking of food so that for about ten days she was fed entirely by rectal injections. For many days she suffered the greatest agony from dyspnoea and a continual palpitation of the heart.

At no time was there or had there ever been any marked irritability of the bladder or abnormality in the urine, any paralysis of the sphincters of either the bladder or rectum, any tendency to bed sores or to sores upon the prominent points of pressure. The powers of life had rapidly failed, however, and death finally put an end to her sufferings quietly and without pain after a final illness of about three weeks.

*Autopsy.* The autopsy was made by me thirty-six hours after death, in the presence of Dr. Jos. H. Warren, of Boston, and Drs. Z. B. Adams, L. M. Palmer, and E. H. Bigelow, of Framingham. The muscular system was seen, upon inspection, to be markedly wasted, but there was a considerable layer of adipose tissue found over the walls of the abdomen. The omentum was atrophied, stomach and intestines empty. The mucous layer of the stomach was injected to a considerable degree. The right ovary was healthy but upon the left a small cyst was found. Uterus small. Kidneys small but otherwise normal. Bladder healthy. In the thorax there were a few pleuritic adhesions, but the lungs were apparently healthy. There was no abnormal amount of pericardial fluid and no disease of pericardium. The brain for various reasons was not examined.

Upon opening the vertebral column the membranes of the cord were found to be deeply injected and markedly adherent to the bony walls. In section the cord was seen to be asymmetrically atrophied, pale and in local areas softened. Portions of it from the dorsal and lumbar regions were reserved for microscopic examination since they were thought to represent in a sufficient degree the pathological changes that had taken place. I hardened them in Muller's Fluid, and after an incomplete examination sent portions to Dr. James J. Putnam, Lecturer on Nervous Diseases in Harvard University. To his kindness and attention, and to the patience and skillfulness of Dr. Henry P. Quincy, Instructor in Histology in the Harvard Med-

ical School, in preparing the specimens, I am indebted for the following detailed pathology.

"The four pieces of spinal cord which were sent to me for examination were in a well-hardened condition and comprised the whole or greater part of the lumbar and a little of the lower dorsal regions.

"They were imbedded in celluloidine, and their sections were cut with the microtome, stained with Beale's carmine or hematoxyline and mounted in Canada Balsam. Sections were also made and very beautifully stained and mounted according to Weigert's method, by Dr. H. P. Quincy.

"Certain abnormalities in these sections were visible even to the naked eye.

"The *shape of the cord was altered*, apparently from shrinkage of the posterior half, so that the central canal appeared displaced backward.

"The left postero-lateral column in the lumbar region looked as if sliced away in part, although special care had been taken to avoid pressure during hardening.

"Intense sclerotic changes occupied almost the whole of the posterior columns, both antero-lateral pyramid tracts in the dorsal region and the remnant of the crossed lateral tracts in the lumbar region.

"When examined under low powers, the following additional changes were observed:—

"The *central canal* was entirely blocked with round cells which took up the coloring matter of hematoxyline, and all trace of columnar lining was gone.

"The *posterior columns* were occupied by a dense connective tissue, as in advanced cases of locomotor ataxia, in which nerve fibres were very sparsely scattered, either singly or in small groups. These nerve fibres were less abundant in the lower dorsal than in the mid-lumbar sections, and, in fact, were almost literally absent in a good part of the sections from the former region.

"That portion of the posterior columns immediately adjoining the posterior commissure was, as is so often the case, relatively little affected.

"The *sclerosis of the antero-lateral tracts was not so intense* as that of the posterior tracts and posterior nerve roots.

"These changes—*increase in the connective tissue, diminution in the number and size of the nerve elements and alteration or disappearance of the myelium*—were visible, not only in the posterior columns but to a greater or less extent over the entire section of the fibrous mantle of the cord.

"The *region of the anterior nerve-roots was comparatively healthy*, and strands of apparently healthy axis-cylinders were seen making their way outward from the anterior cornua.

"Compared with the abundant net-work of horizontal motor fibres usually seen in the lumbar enlargement of a healthy cord, the number of these here present was very small. The condition of the posterior as compared with the anterior nerve-roots was strikingly brought out by the Weigert staining. The posterior roots seemed to contain scarcely a single healthy fibre, whereas the fibres of the anterior roots, though somewhat sparse, were relatively abundant.

"The pia mater was thickened over the posterior and lateral columns and the tissue immediately adjoining was more or less sclerosed.

"The *nerve cells of the anterior and posterior cornua* were at all levels far less numerous than normal. In some sections only a scattered few were visible, the

greater number being in the anterior and lateral groups.

"The cells of the median and internal areas of the anterior cornua were even smaller and paler than usual, and the whole region presented a confused, ill-differentiated appearance. The pericellular spaces looked larger than normal, and although this may have been due to shrinkage during hardening, yet it may be doubted whether such shrinkage would have occurred in a healthy cord.

"A point of anatomical interest was the presence of a *small, supplementary canal* a little posterior to the main central canal and separated from it by a thick partition of periepithelial tissue. It extended throughout almost the whole of the lumbar region.

"Under still higher powers, it was seen that most of the nerve cells which remained were altered to a greater or less degree and in various ways. Failure to absorb carmine well, absence of processes and a granular texture were common changes. Here and there a small vacuole was seen, in one section a very large one.

"Some cells were reduced to granular masses; a few were globular, pale and homogeneous. The *nucleus* was sometimes entirely absent, sometimes it had entirely lost its outline and was only to be distinguished

AR, Anterior nerve roots healthy. AL, Antero-lateral tract diseased. C, Central Canal. P, Posterior columns diseased. PR, Posterior nerve roots diseased.

AR, Anterior nerve roots relatively healthy. L, Lateral tract diseased. P, Posterior columns diseased. PR, Posterior nerve roots diseased.

from the rest of the cells as a reddish flush with the nucleolus in the centre. Sometimes again it was shrunken and angular. The *nucleolus* appeared at times unusually large and dense; in the cases where

this was seen, the nucleus, whether by accident or not, looked shrunken or indistinct. Occasionally no nucleus was seen.

"Some strands of the *anterior nerve roots* were markedly atrophied while others near them looked comparatively healthy. The myelinel was often conspicuously deficient.

"There was no marked hypertrophy of axis cylinders anywhere, but often a moderate increase in size of single fibres, especially in the posterior columns. Atrophied fibres were very common, and on the whole, the variation in size was much greater than normal throughout the whole section but especially in the posterior columns. Increase of Deiter's cells was not a marked feature.

"In the more intensely sclerosed portions, the tissue was filled with granular-looking material, and collections of this same material were especially noticeable around the small arteries. The *walls of the arteries* themselves in the sclerosed areas were, as a rule, *markedly hypertrophied*. The same was true of the central artery and the arteries of the nerve roots.

"Here and there in the posterior nerve roots were seen collections of corpora amylacea, or at least homogeneous pale bodies of about their size."

*Summary:* In brief, the pathological changes seem to have been a sclerosis of the posterior columns of the cord and of the motor tracts of the lateral columns together with a destruction of nerve fibres in the posterior cornua and to a certain extent in the anterior cornua, although many of the nerve roots in the latter were comparatively healthy. This increase of connective tissue, however, was not scattered irregularly through the cord as in disseminated sclerosis, but was continuous throughout the length of the columns; nor was it by any means confined to the posterior columns as in the classic locomotor ataxia. The disease seems rather to indicate an *incompleteness of nerve or cell development* in certain well-defined portions of the cord.

CASE V. Jessie, aged twenty-six, began to notice at the age of eight the same ataxia that she had seen in her three older sisters. She did not have the premonitory symptom of palpitation of the heart but has had marked cardiac trouble in recent years. Has had rheumatic fever twice. An examination of the heart showed signs of hypertrophy with an apex murmur transmitted to the back (mitral). There was also a venous hum in the carotids, showing a marked anaemia of the system. The ataxia in the beginning was unattended by other symptoms and gradually invaded the upper extremities, but has never been so pronounced in them as in the lower limbs. She had not and never did have "wrist drop." She could extend the arm level with the shoulder but not steadily — there was a marked muscular tremor. There was a tremor also of the head whenever she attempted to move it or perform other voluntary movements.

In the lower extremities the ataxia had progressed so far that she had been unable for years to walk without the assistance of the chairs and tables in the room and even then often falls helpless to the floor. Her gait resembled the spastic gait seen in disease of the lateral columns. She could get no aid from a cane, because she could not direct it properly. She could turn around only with the greatest difficulty and fell immediately if she closed her eyes. She complained of a feeling of cushions under the feet. In descending the stairs she always puts the right foot for-

ward and it involuntarily jerked up and down as though it were suspended by a spiral spring. All her movements were of necessity slow and methodical.

There did not seem to be any muscular paresis, but only a lack of coordinating ability. There were no contractures and she had never had muscular spasms. Muscular irritability was decreased to both the faradic and galvanic currents and this decrease was more pronounced on the right than on the left side, and in the lower than in the upper extremities. The tendon reflexes were absent, but plantar reflexes present. There was a right lateral deviation of the spine and a *tendency to cyphosis*. Of recent years she had complained of neuralgic pains in the lower limbs, but had only a very slight and infrequent girdle sensation. The sensibility of the skin was so decreased that, like her sister Clara, she was unable to distinguish between pinching, pricking and rubbing it, but there had never been any formication. There was no deafness, no atrophy of optic disk nor indistinctness of vision, but there was a slight nystagmus.

Under the influence of an abundant, nourishing diet and of occasional small doses of nitrate of silver, her condition in June, 1885, shows an improved tone of the system and possibly a slight amelioration of the morbid symptoms.

CASE V. Myra, in October, 1882, at the age of fifteen, had for more than a year been unable to walk even a short distance without unusual fatigue. She had right lateral curvature of the spine and a gait that was clearly ataxic. The tendon reflexes were normal and the only sign of impairment of the functions of the upper extremities was a slight waviness in the lines of her handwriting. Reactions to electrical currents were normal. She had never complained of girdle or neuralgic pains but had felt at times a tendency to stand upon the toes instead of squarely upon the feet and always walked with irregular speed, a few hurried steps alternating with a slower movement.

She was taken from school and in June, 1885, remains in practically the same condition as when I first saw her, her symptoms showing no very great progression. The tendon reflex has, however, disappeared but the plantar reflex is still present. Considerable ataxia can still be detected although the gait is considerably improved.

CASE VI. J. W. W., farmer, aged sixty-six, was prostrated in January, 1881, with an acute attack of rheumatism, involving principally the knees and ankles. He had been cutting ice the previous week and had thoroughly wet and chilled his legs. A severe gastritis speedily followed and lasted for about three weeks. For many years he had been subject to occasional nausea and vomiting and to habitual constipation. He had never had any colic pains nor any impairment of motion in either the upper or lower limbs, even at the time when lead was found in the drinking-water. But now he began to complain of weakness in the legs and an oedema in them at night. The heart, upon examination, was found to be dilated and irregular in its action, but free from valvular lesions. The urine per diem was about one half the usual amount and contained mucus, bacteria, and calcic oxalate crystals in great abundance. No casts. Sp. gr. 1020.

He soon began to complain of a constant pricking sensation in the feet and legs, but has never complained of fulgurating pains. As one of the *earliest* symptoms, he spoke of a girdle sensation around the

body and of a feeling of heat in the same area. The gastrocnemii muscles were tense and tended to elevate the heel. It was only with the greatest difficulty that he could manage to walk, and he always felt as though he were treading on velvet. He was obliged to use two canes. The gait was purely ataxic. To turn around quickly, or to stand with the eyes closed, were acts that were equally impossible to him. Vertigo was a constant symptom but was greatly increased when he was standing. At the base of the brain there was a "burning" sensation, as he described it, and his wife often found him in his sleep pressing the back of the neck with his hands.

The muscular weakness, but not the ataxia, quickly invaded the upper extremities and affected chiefly, if not wholly the flexor muscles. The tendon reflexes were present and electrical reactions normal or even slightly increased. Of the eyes I made no careful examination, both on account of his age and because they were seriously injured years ago by an explosion of gunpowder.

Under treatment with the nitrate of silver (gr. one half combined with extracts gentian and nux vomica, three times a day) continued for periods of three weeks and then omitted for equal lengths of time, the girdle pain together with the muscular weakness and ataxia almost wholly disappeared for the space of four months. In December, 1884 the ataxia began to return, but under treatment speedily disappeared again.

This case in its details differs somewhat from the manifestations of the disease as it has appeared in its early stages in the girls of the family, but is especially noteworthy from the fact that in the majority of the few recorded cases of this degenerative disease the initiatory symptoms have appeared prior to the age of twenty, and in none later than the age of twenty-four. (See table at end of paper.)

**Differential Diagnosis:** The differential diagnosis of these cases is difficult and demands the consideration of many diseases. I will briefly outline some of the symptoms in these diseases that might lead to errors of diagnosis, and that have led to such errors in past years in some of these very patients.

**Lead Poisoning:** The symptoms in their order of appearance and frequency are colic, arthralgia, paralysis and encephalopathy. (Tanquerel.) Lead is always to be detected in the urine but the blue line on the gums is sometimes absent.<sup>2</sup> The paralysis is confined almost entirely to the extensor muscles; is usually in the forearm and rarely becomes general, although paralysis of the lower extremities is recognized.<sup>3</sup> Muscular atrophy is secondary to paralysis. Electro-sensibility and contractility are markedly reduced. All the symptoms are rapid in invasion and disappear readily under proper treatment.

**Cerebellar Disease:** This disease is characterized by a reeling, rolling gait, not ataxic, but compared by Hughlings Jackson to the gait of a drunkard. Vomiting and sub-occipital pain are prominent. *Tendon reflex is not abolished.* (Serpelli.) The pupils, as a rule are contracted and do not react to light. There is no diminution either of motion or sensation. Paralysis is rare until near death; if it occurs it is due to disease in other nervous tracts and is accompanied by rigidity and local spasms.

**Cerebro-Spinal Sclerosis:**<sup>4</sup> *Disseminated Sclerosis:*<sup>5</sup> *Insular Sclerosis:*<sup>1</sup> In the ascending form, the first symptom is a gradual loss of power in the lower limbs which later become agitated by tremors. The gait is usually not ataxic but more like that of general paralysis. As the disease progresses, the upper limbs and cranial nerves become involved. The second stage is marked by rigidity, spasmodic contractures, and an aggravation of the tremor. Electro and reflex irritability are greatly increased. Epileptiform and apoplectiform attacks occur.

In the descending form, on the contrary, the tremor is the primary symptom and is first noticed in the muscles controlled by the cranial nerves. In the second stage there is paresis of the upper and later of the lower limbs with permanent contractures.

In the third stage of both forms there are incontinence of urine and feces, bed sores, facial paralysis and dementia. The microscope shows a degeneration irregularly scattered through the motor tracts of the brain and antero-lateral columns of the cord.

**Antero-Spinal Paralysis:** (Anterior Poliomyelitis, Erb.) The invasion of paralysis is usually sudden during an acute attack of fever although it may be without fever. The paralysis attacks the lower extremities and extends upwards involving the muscles of respiration and deglutition.<sup>6</sup> It is complete but soon partially disappears. There is rapid muscular atrophy differing from progressive muscular atrophy in being secondary and in involving whole groups of muscles. Electro irritability is early lost. There is no anesthesia, incontinence or paralysis of sphincter ani, differing thus from general myelitis.

**Diseases of the Lateral Columns:** The positive symptoms are paresis with rigidity and contractures (often talipes equinus) and an increase of all forms of reflex excitability, especially in the tendons. Among the negative symptoms is the absence of muscular atrophy, of ataxia, and of cerebral, rectal and vesical complications. In the more common variety, *Tabes Dorsalis Spasmodique*, of Charcot,<sup>7</sup> *Spasmodic Spinal Paralysis*, of Erb,<sup>8</sup> *Tetanioid Paraplegia*, of Seguin, initial sensory symptoms have been reported. Then come the paresis, motor irritation, the spastic gait and contractures. No autopsies have been reported, however, which reveal uncomplicated lateral degeneration.

**Antero Lateral Spinal Sclerosis:** This begins without fever and is characterized by loss of power in the upper extremities followed by a general atrophy of the muscles of the paralyzed limbs, "atrophy en masse," of Charcot. Later, the lower limbs are similarly invaded and in a greater degree. The cranial nerves are speedily involved so as to simulate bulbar paralysis. *Muscular coordination is intact.* There are no neuralgic pains.

**Chronic Myelitis:** There is a tingling spinal pain and girdle sensation but no neuralgic pains in the extremities. Electro contractility and reflex excitability are markedly increased. Paralysis of motion and violent muscular spasms in lower extremities. The functions of bladder and rectum are disordered.

**Pseudo Hypertrophic Muscular Paralysis:** Is an hereditary disease of infancy, expressed by increase of

volume and hardness of certain muscles, especially in the lower extremities; by *secondary atrophy and paresis* and by conservation of cutaneous sensibility and the functions of the bowel and bladder.<sup>11</sup>

*Progressive Muscular Atrophy: Atrophy of muscles in hand and fore arm.* "main en griffe" is the first marked symptom, although a slight loss of power in the upper extremity may be early noticed.<sup>12</sup> The atrophy is rarely symmetrical and may invade muscles in all parts of the body.<sup>13</sup> Paralysis is always *secondary* to atrophy and finally invades the muscles of respiration. Electro contractility is decreased but not abolished.

*Locomotor Ataxia:* The introductory stage which often lasts for years is characterized by *lancinating neuralgic pains* in the lower extremities, in the trunk (generally) and in the upper extremities (more rarely); by *paræsthesia* and often *anæsthesia of the lower extremities*, by *girdle pains*, motor disturbances, gastralgia and irritability of bladder and sexual organs. There is often amblyopia, diplopia, or amaurosis with marked head symptoms. The tendon reflexes begin to disappear.

In the fully developed disease, which may last from five to twenty years, there is an increase of all these symptoms with ataxia of the lower extremities. Later this ataxia may in some cases invade the upper extremities. The gross strength of the legs is unimpaired. The tendon reflexes are lost but *electro irritability is preserved* and often greatly increased. There is *atrophy of the optic disk*. The final stage is short and is characterized by paresis and contractures, by muscular waste, by *bed sores* and *paralysis of sphincters of bowel and bladder*. Death is either by exhaustion or some intercurrent disease.

*Degenerative Ataxia:* The introductory symptoms of this complex disease which we have been considering are slight, and consist for the most part of dyspnea and an irritable heart and stomach. Occurring in girls and before or at the age of puberty, they might easily be confounded with the ordinary symptoms of anemia and escape particular notice. But the patient is conscious of a certain *weakness in the lower limbs* which renders the movements of the feet hesitating and uncertain. Sooner or later this irregularity of motion becomes apparent to others. The tendon reflexes have not yet been affected. There are *no lancinating or girdle pains*, and *no disorders of sensation*. Such symptoms may last with little change for months or even years.

The first stage of the disease is characterized by a *gait* that is clearly *ataxic*. Not only has standing become a difficult act but turning around is still more difficult. The motor incoordination which at first affected only the lower limbs has extended gradually to the upper extremities. There are irregular *oscillations of the head* that are aggravated in their severity by attempts at voluntary movement in any part of the body. Whether the wrist drop that was observed in two of these cases is a symptom of the spinal disease may well be called in question, since we have evidence of lead poisoning in the family some years ago.

In the father, the girdle pain was one of the earliest symptoms but in all the other cases it has occurred *very late* in the disease. Nor is this the only symptom

that distinguishes this form of ataxia from the classic locomotor ataxia. There are *few, if any disorders of sensation*, such as wandering pains or anæsthesia. There may, however, on the contrary, be hyperæsthesia. The *tendon reflexes disappear* in time, as do also the electro reactions of sensation and muscular irritability. Strange to say, the *plantar reflexes may be retained*. This stage will last for years, with little change, temporary improvements alternating with speedy relapses.

The second stage marks the fully developed disease. The incoordination has progressed so far that both *walking and standing have become impossible*. Nor is it any longer possible to execute free movements with the hands or arms, to work or feed oneself. The unfortunate sufferer must sit or half recline, a helpless burden in a chair. Yet there has *not been a true or complete paralysis*. Muscular atrophy and contractures begin to be well marked and produce a great distortion of the limbs. The *skin is anæsthetic* but is of fair vitality, and *pressure sores do not occur*. The *speech has a peculiar drawl* and finally becomes unintelligible. The signs of bulbar paralysis appear. *Neuralgic and fulgurating pains* begin to be distressing, and the attacks of dyspnea and collapse are frequent. There is *no paralysis of the sphincters* and little if any irritability of the bladder.

The final stage is brief. The patient is confined to the bed a few weeks only and in the two girls of this family that have died, the symptoms were those of meningitis and an acute myelitis affecting the lateral columns. The probability nevertheless exists that some intercurrent disease rather than the spinal degeneration would prove in many cases the actual cause of death.

*Causation.* The causation is obscure. No differentiation of the disease from complex cases of the ordinary locomotor or progressive ataxia of Duchenne was made until 1861, when Professor Friedreich of Heidelberg presented six cases which seemed to require a new and separate classification. It was not, however, until 1863 that these observations were published<sup>14</sup> and I can find by the most careful study only forty-three cases upon record that unquestionably agree with Friedreich's in clinical and pathological history.<sup>15</sup>

The disease has been called hereditary but the cases of *direct transmission* are very few. It is certainly, however, a *family disease*, and in the majority of the recorded cases there has been found in the parents not an ataxia, perhaps, but certain mental and nervous peculiarities. Above all causes Brousse<sup>16</sup> mentions alcoholism and consanguineous marriages, and in my cases the history of alcoholism in previous generations is well established. Seigniquier<sup>17</sup> noticed in his cases habits of onanism. I made careful investigations to detect this habit in my patients, and believe I am justified in saying it did not exist. Even if it did, it may not bear a causative relation to the disease.

According to Friedreich the disease is one of puberty. The age at which the initiatory symptoms occur varies, however, from six to twenty-four years, while in one of my cases it was undoubtedly sixty-six.

<sup>17</sup> Cruveilhier. Arch. Gén. de Méd., May 1853.

The sexes seem to be about equally affected, although the majority of my cases were females.

*Treatment.* The treatment is rather unsatisfactory. Little or no hope can be entertained of permanent recovery, and the most that can be done is to render the condition of the patient comfortable. Cod liver oil, if the stomach will bear it, and concentrated animal foods are absolutely essential to maintain the physical strength. Iron I found to be ineligible, nor did I succeed any better with the vegetable tonics. Phosphorus for a time worked well, but its effects were transient at the best. In the nitrate of silver well pushed and the application of electricity, I consider we have the two best means of giving relief that are really practicable and available. Persistent cauterization over the spinal column has been reported to be attended with good results, but private patients are few who would submit to the procedure.

TABLE OF CASES OF HEREDITARY ATAXIA.

No.	Observer.	No. in same Family.	Sex.	Date of symptoms.	Family History.
1	Friedreich	2	M	18	Hereditary; mother hemiplegic; father a drunkard.
2	"	1	F	18	"
3	"	4	F	16	Hereditary; mother of limited intelligence; father a drunkard, and died of phthisis.
4	"	1	F	16	"
5	"	1	F	16	"
6	"	1	M	15	"
7	Eulenborg	3	F	13	No special heredity; five brothers and sisters died young.
8	"	1	F	13	"
9	"	1	F	13	"
10	Carre	7	M	—	Direct heredity; mother, grandmother and an uncle ataxic.
11	"	1	F	—	"
12	"	1	M	—	"
13	"	1	M	—	"
14	"	1	M	—	"
15	"	1	M	—	"
16	"	1	M	—	"
17	Güncke	2	M	7	No heredity; father a drunkard, other family history good.
18	"	1	F	—	"
19	A. Carpenter	2	F	—	Family history good.
20	"	1	F	—	"
21	J. H. Kellogg	2	M	6	Hereditary; an ataxic brother died at 20, and several cousins had similar disease.
22	Schmid	1	M	6	"
23	Gowers	5	M	19	Hereditary; mother had chorea; one brother and two half-cousins insane.
24	"	1	F	18	"
25	"	1	M	19	"
26	"	1	M	—	"
27	"	1	M	—	"
28	Seeligmüller	2	M	12	Consanguinity and some nervous peculiarity in family, but no ataxia.
29	"	1	M	12	"
30	Schmid	2	M	12	Father a drunkard; other family history good.
31	"	1	F	—	"
32	Brousse	1	F	21	Direct heredity; grandmother died of phthisis; mother of ataxia; father of cerebral softening.
33	Ritmeyer	8	M	11	History in family of various nervous affections, chorea and poliomyelitis.
34	"	1	M	7	"
35	"	1	F	6	"
36	"	1	F	6	"
37	"	1	F	6	"
38	"	1	F	6	"
39	"	1	M	4	"
40	"	1	M	4	"
41	"	1	M	7	Father and mother were drunkards.
42	"	1	M	7	"
43	"	1	F	7	"
44	W. L. Smith	6	F	6	Some hereditary influence; grandmother died with ataxic symptoms; history of alcoholism.
45	"	1	F	6	"
46	"	1	F	9	"
47	"	1	F	8	"
48	"	1	F	13	"
49	"	1	M	66	"
50	J. J. Putnam	2	M	4	No history of heredity; history of neglect and induration; followed scarlet fever in the boy.
51	"	1	F	4	"
52	J. C. Seguin	1	F	10	No heredity; family history remarkably good.
53	"	1	F	7	"
54	"	1	F	7	"
55	"	1	F	7	"
56	"	1	F	7	Mother died of consumption; other family history good.
57	"	1	F	7	"

\* Since the writing of this paper, Dr. J. J. Putnam has showed me notes of his cases that he had seen, and Dr. J. C. Seguin has reported a case in *New Eng. Med. J. and Surg. Jour.* June 13, 1885.

- Dr. Frederick P. Henry, of Philadelphia, has made, according to the *Polyclin.*, a number of microscopic examinations of the blood during and after typhoid fever, and finds that while the number of red corpuscles is fully up to or above the normal standard during the fever, during convalescence it often sinks considerably below the number found in health. This he explains as a latent anæmia, the loss of water from the blood during the disease causing a relative increase in the number of red corpuscles. This view leads him to the belief that typhoid fever patients should take water as a medicine, as well as to relieve their thirst. He quotes the late John F. Meigs, of Philadelphia, who expressed similar views in one of his lectures at the Pennsylvania Hospital in 1880.

A CASE OF PROGRESSIVE MUSCULAR ATROPHY FOLLOWING A BLOW ON THE HEAD.<sup>1</sup>

BY WILLIAM N. BULLARD, M.D.,

Physician to the Department of Diseases of the Nervous System, Boston Dispensary.

GENTLEMEN,—The patient whom I have the honor of bringing before you to-night is a man sixty-one years of age, a teamster. Previous to the present trouble, he had always enjoyed good health, and there is no history obtainable of any constitutional disease, neither of rheumatism nor syphilis.

On the 10th of March, 1884, he was struck on the left side of the head by a staging which fell, and was knocked down thereby. There seems to have been no absolute loss of consciousness at the time, though he does not remember subsequent events very distinctly. He is, however, positive that there was no blow on the neck or shoulder. Immediately after the injury, he felt severe pains in the head and back of the neck, especially on the left side which extended to the left shoulder. These pains were darting in character and quite severe, and there was much pain on attempting to move the head or to bend the neck to the right. Shortly after this he began to notice weakness and atrophy of the muscles of the left arm and hand, which gradually spread to the corresponding muscles on the right side. There was a sensation as of pins and needles in the two internal fingers of the left hand.

When he was first seen by me at the Boston Dispensary on the 10th of July, 1884, four months after the injury, his condition was as follows:

He complained of constant pain in the left side of the head and neck, and of severe darting pains running down the side of the neck, which were momentary and occurred especially at night, sometimes as often as twenty times a night. He had the paræsthesia before mentioned of the two internal fingers of the left hand and there was much weakness of the muscles of the left arm, forearm, and hand. There was also, according to his statement, some loss of memory and dizziness, which at times caused staggering.

On examination, nothing abnormal was detected about the head. The muscles of the shoulder and back on the left side were found to be markedly atrophied, while there was distinct atrophy, though less marked, of those of the upper arm. The muscles of the lower arm were also affected, but to a less degree than those of the hand. The latter was *en griffe*, the fingers partially flexed; both the thenar and hypothenar eminences were flattened and the interossei were distinctly diminished in size. All movements, including extension of the thumb, could, however, be performed, although some of them imperfectly. There was slight atrophy of the corresponding muscles of the right side. Sensation was diminished (as thesiometer) over both arms. The reaction to electricity at this time was, however, normal. The lower limbs were normal except for varicose veins.

In the following September we find the pain still continuing in the head and neck, but as before, there was no marked tenderness to pressure over the head, neck, or spine. At this time the upper arm measured over the biceps had a circumference of 25 cm., right, 23.5 cm., left; the lower arm just above the wrist, 16 cm. on both sides. Dynamometer (normal over 100) right, 43; left, 48. The muscles of the left arm re-

spond more strongly to Faradic than those of the right, but the Faradic reaction is diminished in both; the extensors of the left forearm respond with great difficulty. There were marked fibrillary contractions in the muscles of both arms.

The patient was not seen again until November 14th. Three weeks previous to this he had slight hæmoptysis, and on examination, signs of consolidation were found at the apex of the left lung. The heart-sounds were normal and the apex-beat in the normal position. Urine did not contain albumen. There was some tenderness on pressure over the left trapezius and the muscles of the back and left side of the neck. Sensation in both arms to the æsthesiometer was normal. Dynamometer (normal over 100) 50 in each hand. At this time, he could not write on account of tremor of the right arm. Measurements at this time were as follows: right biceps (circumference) 23.5 cm.; left, 23 cm.; right forearm, 17 cm.; left, 15.5 cm. All movements can be performed. There was slight numbness in the fingers.

Throughout the following months the patient, who was not able to attend the clinic regularly on account of the illness of his wife, who finally died of phthisis, grew gradually worse. The weakness and atrophy increased and each muscle in the arms stood out apart and distinct from the others. In the spring, however, a slight improvement took place in his condition. The pulmonary symptoms diminished in severity. There was no hæmoptysis after the first. He still complained of constant discomfort and pain over the vertex, with dizziness. He was entirely unable to work on account of the weakness of his arms, while he could walk well. On the 12th of May, a physical examination showed a continuance of the pulmonary signs and the chest was much emaciated. Deep hollows existed both above and below the clavicles, and the intercostals were somewhat atrophied.

Right arm over the biceps contracted to its full extent, measured 26 cm.; left, 25.5 cm. The middle of the upper arm, right, 21.5 cm.; left, 24 cm. Wrist, right, 17 cm.; left, 15.5 cm. These measurements showed a distinct decrease of the atrophy in the upper arms.

Faradic reaction (Fleming's battery, one cell; numbers denote inches on rod). Positive pole placed on deltoid. Deltoid, right, 1; left, 1½; biceps, right, 0; left, 1½. Brachialis anticus, right, 1; left, 3¼. Extensors of lower arm, left, 3¼. Right deltoid contracts at ¾ without contraction of extensors. Supinator longus, right, 2½; left, 2¼. Flexors of lower arm, right, 1; left deltoid affected at 2¼. Interossei primus (K on flexors lower arm), right (1¼ flexors of thumb contract); left (flexor communis contracts at 2; no effect on interossei. With tr. on the ulnar nerve and et. on extensors of the forearm, right, 2½; left, 1½. Skin reflex much increased. Fibrillary twitches still marked. At the present time, we find the Faradic reaction much diminished over the muscles of the scapula and upper back, and also over the trapezii,—much more so than in the muscles of the upper extremities. Sensation in these parts, however, is normal, as also over the extremities, to the æsthesiometer, but is diminished to F.

There is now very marked atrophy of the muscles of the upper back and shoulders, that is, of the trapezii, the supra-spinati, the infra-spinati, the rhomboides, and the levatores anguli-scapulae, which has gradually,

<sup>1</sup> Read before the Section for Clinical Medicine, Pathology, and Hygiene of the Suffolk District Medical Society, June 9, 1885.

but steadily, increased since July. The scapulae are very prominent and their lower angles stand away from the ribs.

That we are still on the threshold of our knowledge in regard to the various forms of progressive muscular atrophy, will scarcely be disputed. Erb, in his article on the juvenile form of this disease, says: "Even yet is our knowledge of progressive muscular atrophy to be designated as thoroughly incomplete, indistinct in regard to many points and contradictory; indeed we appear, perchance, to be farther removed from a clear conception and fixed idea of these diseases than those who, now more than thirty years ago, first described them, or than the others who in the two following decennials busied themselves with their scientific investigation."

Most authorities, however, are now agreed that two principal divisions of these diseases may be made. I. Those series which are due to disease of the spinal cord (and of the nerves connected therewith); and II. Those in which the original lesion probably exists in the muscles themselves. It is proposed by Erb that cases of the first class be distinguished by the name of "Amyotrophie spinalis progressiva," while those of the second are designated under the title of "Dystrophie muscularis progressiva."

The second class includes *a.* pseudo-hypertrophic paralysis; *b.* Erbs' Juvenile progressive muscular atrophy; *c.* Duchenne's Infantile progressive muscular atrophy; *d.* Leyden's Hereditary form of progressive muscular atrophy; and *e.* Charcot's Transitional form. It is very probable, however, that it will be found impossible to maintain all these varieties as distinct diseases, and that some of them are simply varying manifestations of the same disease. Even now, Erb and his followers deny the existence of Leyden's hereditary form as a distinct variety, and would class the cases reported either under the juvenile or the infantile types.

We have here, however, to deal rather with a case belonging to the first class — due to spinal disease. This class of cases was at one time divided clinically by Charcot into two divisions: 1. The Protopathic — those cases due to disease confined entirely, or at least principally to the anterior horns of the cord, or in which symptoms referred by common consent to this portion of the cord predominated. The so-called type Duchenne-Avian. 2. The Deutero-pathic, in which the lesion of the anterior cornua and its nerve-cells is a "fact of the second rank," at any rate consecutive. This form may occur with several other diseases of the spinal cord or its membranes, but is most common in connection with lateral sclerosis, then forming the disease known as Charcot's amyotrophic lateral sclerosis. It also exists at times in connection with disease of the posterior columns, or more commonly, perhaps, with chronic cervical pachymeningitis.

Now to resume in short the history of our patient. What has been the course of the disease in his case? A man of sixty, previously healthy and with no hereditary or acquired taint, as far as can be discovered, receives a severe blow on the side of the head near the vertex. Immediately after, he has severe lancing pain in the side of the head and neck, extending to the shoulder and down the back, followed by gradually increasing weakness of the upper extremities with some paresthesia and anesthesia on the side of the injury. This weakness is accompanied by a progressive,

atrophy of the muscles of the shoulder, back, and upper extremity of the side injured, which, after a certain time, involves the corresponding muscles on the other side. There is likewise, a certain diminution in the electric reaction of the muscles involved. After the lapse of nearly a year from the date of injury, we find a gradual improvement taking place spontaneously, not only in regard to the symptoms of irritation, the pains and anesthesia of the arms, but also in regard to the atrophy of the muscles of the extremities. On the other hand, the anesthesia of the back is marked, and the atrophy of the muscles of the back and shoulders has rather increased than diminished.

It is not necessary for us to enter here into an analysis of the symptoms presented; but we can say that in all probability, the case before us is one of deutero-pathic spinal atrophy, due to an inflammation extending to the anterior cornua from other tissues, and that it is probable that the original lesion affected the spinal meninges. The provisional diagnosis in this case would consequently be chronic cervical pachymeningitis with consecutive inflammation of the anterior cornua.

The first author to describe accurately and thoroughly this class of cases was Charcot, who in his "*Leçons sur les Maladies du Système Nerveux*," places them before us in the most striking manner. Vulpian, Gull, and Joffroy have published interesting cases of this sort, and described at length the various symptoms which appeared. The diagnosis in Gull's cases and in that of Joffroy were confirmed by autopsies.

Of especial interest to us in this connection, is Gull's case, No. XXV, from its similarity in many respects to the case before us. It is as follows: A man aged forty-nine, a coal-wagoner, was forced backwards from his seat by striking his head against a beam, whilst driving under an archway, and fractured several ribs on the left side from his fall. Some months after the accident, he began to suffer pain running from the occiput down over the shoulders, and in about a year, the muscles of the upper extremities began to waste. After two years, there was incontinence of urine, which had come on gradually. Three years after the accident, the patient presented a remarkable example of muscular atrophy without actual paralysis. The upper extremities were principally affected. The extensors of the right hand, the muscles of the thumb and the interossei were extremely wasted and there was wrist drop. The muscles of the shoulder and arm, including the pectorales, were also much wasted, but decidedly less so than those of the forearm and hand. There was very slight diminution of sensation. He could still raise the arm over his head. The left arm was affected similarly as regards atrophy, but to a less degree. There was numbness through the whole arm down to the fingers and severe neuralgic pains. The trapezii, serrati-postici superiores, rhomboidei, and all the long muscles of the back and neck, were remarkably atrophied. The supra-spinati were also atrophied, but less so than the infra-spinati and levatores anguliscapulae. The spinous processes were prominent, but there was no tenderness anywhere. The legs were wasted and weak, but the patient could walk. The sphincters were weak; there was dribbling of urine. The head could not be supported erect. The sight was dim and the left eyelid drooped. At the autopsy there was found a chronic arachnitis and ependymo-pachymeningitis, with leptomeningitis and pachymeningitis spinalis, with secondary myelitis.

Whether in the present case there is injury to the membranes of the brain itself is, in my opinion, doubtful, although there are certain symptoms which might appear to point in this direction.

In conclusion, let me state distinctly that the diagnosis arrived at here is only intended to be provisional.

In regard to the connection of traumatism with progressive muscular atrophy, there is no lack of cases reported in which injury to the muscles or nerves of the body, shoulders, back or extremities, and even of the face, has been followed by atrophy of a more or less progressive character. This is rarer, however, where we have grounds for belief that the original lesion was situated within the cranium or spinal canal. Rosenthal reports a case following a fall from a roof, in which he thinks that the concussion produced lesions of the cord. Valentiner and Bergmann each report a case of progressive muscular atrophy following a fall on the back. One of Clarke's cases followed a blow on the sacrum. In regard to the cases of Hammond (two), and Russell-Reynolds (one), said to have been of traumatic origin, I have been able to find no details, while those of Leyden and Jacobi seem very doubtful.

The only case that I have found in which sufficient proof was given of the connection between the injury and the disease is that of Gull related above.

# A CASE OF SPINAL ATAXIA WITHOUT LOSS OF SENSATION AND WITH INCREASED PATELLAR-TENDON REFLEX. A CONTRIBUTION TO THE STUDY OF SPINAL ATAXIA.<sup>1</sup>

BY MORTON PRINCE, M.D.,

Physician for Nervous Diseases, Out-patient Department, Boston City Hospital; and at the Boston Dispensary.

THE CASE of ataxia which I am about to describe is one of exceptional interest and especially so when studied in connection with Dr. Smith's very interesting series of cases of hereditary ataxia,<sup>2</sup> with which it has many points of similarity. It resembles hereditary ataxia in the age of the patient (fifteen years) at which the symptoms developed, the absence of anaesthesia and in fact of all sensory disturbances, the presence of anterior curvature of the spine and nystagmus, and the rapidity with which the symptoms developed. It differs on the other hand from this form of ataxia in the facts, of the freedom, thus far, of the rest of the family from the disease, and in the presence and indeed exaggeration of the patellar-tendon reflex. It differs again from ordinary tabes in this last particular, in the presence of nystagmus, in the absence of all sensory disturbances of every kind, of all cerebral, ocular (pareses) and bladder symptoms. It may be a question as to where it should be placed, and indeed the presence of the tendon reflex might be thought to exclude it entirely as tabes, but still I am strongly inclined to believe for reasons which I shall presently state, that it belongs to the systemic spinal ataxias. Another and not the least interesting point connected with the case is the bearing which it has on the disputed question of the pathology of ataxia. There is still a difference of opinion existing among neurologists as to the cause of ataxia. Some holding that it depends purely upon the loss of sensation, (including sense of touch, muscular sense, etc.); others that it is a purely motor disturbance due to an impairment of the motor coordinating impulses. The sensory theory would be disproved if, as Erb has pointed out on the one hand, cases of complete anaesthesia should be discovered in which no ataxia existed, and on the other, if well-marked ataxia should be found with no loss of sensation. A few cases of this latter class have already been reported, and one in particular by Erb,<sup>3</sup> which will be mentioned more in detail later. In this case there was also complete absence of anaesthesia in every form, while the tendon reflexes were present. These cases show that though loss of sensory impulses may possibly by themselves induce the loss of the power of coordinating movements, ataxia must also have a motor origin and probably be due to a disturbance of the motor coordinating tracts. The complete overthrow of the sensory theory would be accomplished by the occurrence of a case of total anaesthesia without ataxia.

Mary D., seventeen years of age on September 23, 1885. Her present illness is dated by her mother from January 3, 1884, when the girl came home from school complaining of weakness of the legs and malaise. She has never since been to school. The mother admits, however, that during the preceding two months, the daughter had not felt well, and complained of weakness. I first saw the patient in the early summer of 1884, and have since examined her

— Affairs in connection with the Board of Pension Examiners for Boston remain about in *statu quo*. Evidence has been secured that a second of the three members of the Board has never received the degree in medicine which he claimed to possess. Meantime, the confidence felt by the Commissioners of Pensions in the character of his appointments does not seem to have communicated itself in any considerable degree to the physicians and other citizens of Boston conversant with the duties of the Board.

from time to time. As her symptoms have remained, with the exception of one or two particulars, essentially the same during all this time, her present condition will be here given, stating at the same time such changes as have occurred in the progress of the disease.

*Gait, muscular power, etc.* The patient can hardly walk or stand without the aid of support. She habitually uses crutches, and only can be made to walk unassisted after persuasion. When left to herself she easily topples over, though she can manage to get across the room. It is evident that she has not the typical ataxic gait, but rather scuffs along with her feet, taking short, slow, careful steps. She gives at first the impression of having advanced paresis of the legs. Further examination showed this, however, to be erroneous; for when supported laterally so that she cannot fall, she can lower or raise herself on either leg. When told to flex and extend her legs against resistance, it is manifest that their muscular strength is good, though I think they are not as strong as normal, when again lateral support is given to her by placing the hands firmly against both her sides, and her courage is restored, she can raise her feet and walk fairly naturally. When walking, or when standing with her heels and her toes together but eyes open, she topples over after a few seconds and must be well balanced to stand at all. With her eyes closed she tumbles somewhat more readily. She stands and walks with her feet wide apart. She does not reel, or pitch in one direction more than another, but rather tumbles like any inanimate thing which has lost its equilibrium. In other words there exists *static ataxia*.

There also exists incoördination of motion of the legs, but in a minor degree. When told to describe a circle on the floor with the toe, a most irregular figure resulted. She cannot accurately touch with the toe any small object, but reaches it by moderately zig-zag movements. It is a question whether more of an ataxic gait would not be shown if she could maintain the equilibrium, and could walk with less caution and more quickly. The left leg is more ataxic than the right. The hands are also ataxic; the left decidedly, the right slightly. This is shown by difficulty in picking up small objects, buttoning her clothes, touching the top of her nose with her eyes shut.

*Sensation.* There is absolutely no loss of the sense of touch, pain or temperature. When I first saw her about fourteen months ago, I thought there was slight diminution of the muscular sense; not very marked, but still sufficient to be detected. I am unable, at present, however, to discover any at all. She recognizes the slightest passive movement of her legs, can accurately locate their position, and can feel the slightest faradic contraction of the muscles. Sensation as tested by faradism is also normal.

There have been no lightning pains or girdle sensations. When first seen in 1881, she said she had a slight feeling of numbness in the legs but this has disappeared. At that time there was no objective anæsthesia.

*Reflexes.*—The patellar-tendon reflexes are not only present, but exaggerated. No ankle clonus, the plantar reflexes can only with difficulty be obtained. The lumbar reflexes are lively.

*Muscles.*—There is no atrophy or rigidity. There is no disturbance of the functions of bladder or bowel, no tremor, nor local paralysis except the possible weakness of legs above mentioned.

*Nystagmus* exists when the eyes are turned to right and left, but none is noticeable when the eyes are at rest. Last June I did not notice the nystagmus, and do not think it was present at that time. I saw it for the first time at the next examination in September.

The eyes were kindly examined for me by Dr. Charles F. Williams in June last, and within a few days by Dr. O. F. Wadsworth. Both report nothing abnormal in the fundus of either eye. As Dr. Williams did not observe the nystagmus, there is additional ground for not believing it to be present in June. There is probably beginning impairment of speech, as indicated by a very fine, delicate tremor of the voice. I at first considered this due to shyness, but it has continued constant and the patient says she cannot speak as easily or fluently as formerly.

There exists marked *anterior curvature of the spine* in upper dorsal region. There have been no psychical symptoms of any kind. No vomiting, headache, or vertigo (excepting slight dizziness when she attempts difficult feats and loses her balance.)

There is no syphilitic history, and no neurosis in the parents or collateral branches can be discovered. Up to date, there have been eight children in the family. The youngest is at time of writing only five days old, and one died in infancy. Of the other six children, I have personally examined four, and found all but the subject of this paper healthy. The mother describes the remaining two free from all disease.

As Mary D. first complained of weakness in November or December of 1883, she was little more than fifteen years old when the first symptoms developed.

That the diagnosis in this case is not placed beyond doubt, must be frankly admitted. But it seems to me that it is highly improbable that the case is one of cerebellar disease, in view of the character of the ataxia and of the absence of all headache, vertigo, vomiting, convulsive attacks, and the normal condition of the eyes.

Of the spinal diseases, the only ones to be thought of are multiple sclerosis and Friedreich's disease. On first seeing the case, I was inclined to regard it as one of multiple sclerosis, because of the lively patellar reflex; but now, after watching the case for nearly a year and a half, I believe the lesion will prove to be that of Friedreich's disease. This view is based on the absence of the peculiar tremor of multiple sclerosis, the absence of ankle clonus, and local paralysis, (especially of the ocular muscles) and of spastic rigidity of the muscles; the absence of all cerebral symptoms, as vertigo, headache, psychical disturbances, etc. Furthermore, it is as difficult to explain the increased patellar-reflex by a multiple sclerosis as by a posterior sclerosis; for any lesion of the lumbar enlargement which would cause the ataxia would abolish the reflex, and if the lumbar enlargement is not involved, the increased reflex is compatible with a posterior sclerosis. This will be referred to again in speaking of the pathology of the disease.

It may be well to recall here the features which distinguish Friedreich's disease from ordinary tabes.<sup>4</sup> In the first place, there is the tendency to attack many members of the same generation in the same family, while ordinary tabes does not run in families. Then Friedreich's disease appears early in life, while ordinary tabes is a disease of middle age or of later life.

<sup>4</sup> A very excellent digest with a table of all the cases up to date is given by Ormerod in Brain, Vol. VII, page 105.

Out of thirty-six cases, in fifteen the first symptoms came on at ten years of age or under, and thirty-two were twenty or under.

In ordinary tabes, pain and anæsthesia are prominent and almost constant symptoms; in Friedreich's form, disturbances of sensibility are usually insignificant, come on late in the disease, and often are entirely absent.

Other peculiarities of the latter form, are the rapid extension of the ataxia from the feet to the hands, impaired articulation, nystagmus, and curvature of the spine. On the other hand, many symptoms which are common in typical tabes are absent in the hereditary variety,—such as lightning pains, anæsthesia, disturbances of the bladder, transient paralysis, loss of pupillary reflex, optic atrophy, visceral lines, etc. (Ormerod). In both, the patellar reflex is absent. It will be noticed that the symptoms in Mary D.'s case present a typical picture of the hereditary form, excepting that none of her brothers or sisters have thus far been attacked (all are younger than the patient), and the patellar reflex is present and rather exaggerated.

There is the youth of the patient, the rapid progress of the ataxia spreading to the arms within six months, the nystagmus, the spinal curvature, and the absence of the other symptoms commonly met with in ordinary tabes. Difficult articulation we should hardly expect to meet at this early stage of the disease.

The fact that no other case has thus far occurred in the same family will hardly militate against this case being regarded as Friedreich's form of tabes, considering the ages of the other children, and also the fact that a case has already been recorded which stood alone in the family. The absence of sensory disturbances is peculiar to this form of tabes.

As to the retention of the patellar-tendon reflex, it is a significant fact that it is not a very rare thing in ordinary tabes for the patellar reflex to be preserved, and two cases<sup>4</sup> have been observed, one by Ross and one by Erb, in which the patellar-tendon reflex was increased.

But more than this, the clinical evidence in favor of regarding the case of Mary D. as one of Friedreich's ataxia (posterior sclerosis) is still further strengthened by three observed cases of ataxia, in one of which *normal* sensation was combined with *normal* patellar reflex, and in the other two with *exaggerated* patellar reflex. These cases are so valuable that it will not be out of place to briefly mention them here. The first case is reported by Erb.<sup>5</sup>

It was that of a man fifty-two years of age, who, when he came under Erb's care, exhibited marked and typical ataxia. When he walked side by side with a patient with typical tabes no difference in the gait could be distinguished. There had been no lightning pains; there was no paræsthesia or anæsthesia of any kind and no girdle pains; the pupils and ocular muscles were normal, there were no bladder symptoms. There were also no cerebral symptoms of any kind. The patellar-tendon reflexes were present. For the same reasons I have given above in the case of Mary D. Erb regarded this case as one of spinal ataxia, though unwilling to commit himself as to the exact lesion of the cord.

This seems to be the place, before giving the other two cases, to speak of Kast's<sup>7</sup> two cases, in which with

slight anæsthesia and no loss of muscular sense at all, there was exquisite ataxia, while the patellar-tendon reflex was present.

The first of these cases was one of myelitis from compression following fracture of the vertebrae caused by a fall. There was complete paraplegia, slight loss of sensation, but gradual motor recovery in eight weeks. When full motor power in the legs had returned, ataxia was developed. Both knee-jerks were readily obtained, but there was no ankle clonus. The plantar reflexes were active. In the right leg ataxia and loss of sensibility to touch and pain were more marked than in the left, but there was no loss of muscular sense; the sphincters were not affected.

The second case was one of acute transverse myelitis, with complete motor and almost complete sensory paralysis of both legs to touch, temperature and pain. In this case also, on return of motor power, decided ataxia developed and persisted even after complete return of motor power. The knee-jerk was well marked and there was ankle clonus on left side but not on the right.

In these two cases a stage intervened between the complete motor paralysis and return of muscular power, in which, with almost complete motor power, there were considerable defects of coordination and ataxia. I have not been able to obtain Kast's original article, and therefore cannot speak positively of the exact amount of sensory disturbance present, but Erb, referring to them says: "there was the most exquisite ataxia, without very marked disturbance of sensibility and especially without any loss of the muscular sense."

The two cases above referred to, wherein normal sensation was combined with increased patellar reflex, were reported by Seeligmüller<sup>8</sup> as cases of Friedreich's disease. They were two brothers whose parents were first cousins, and whose mother and maternal aunt were highly neurotic. Both brothers had locomotor and static ataxia, in one the static being predominant. In both there was absolutely no loss of sensation, and there existed *increased* patellar reflex, and nystagmus. The plantar reflex was absent in both; the abdominal reflexes were present. There was no ankle clonus and no disturbance of speech.

Friedreich, to whom Seeligmüller sent his cases for an opinion, expressed a doubt as to whether they were true cases of his disease, presumably in view of the presence of the retained patellar reflex and the presence of psychological symptoms which existed in both, namely: forgetfulness and dreamy states in one, and forgetfulness, migraine, dreaminess, and inverted sexual passions in the other. But as Seeligmüller points out, the father, who was otherwise perfectly well, had the same forgetfulness, and, as Ormerod remarks, the connection between tabes and paralysis of the insane is well known. Even if there should have been some cerebral disease it would scarcely account for the spinal symptoms. It seems to me, all things considered, that Seeligmüller was more likely right.

Not the least interesting question connected with the case of Mary D. is the seat of the lesions in the cord. It is a remarkable fact, considering the grouping of the symptoms, that out of seven autopsies,<sup>10</sup> of Friedreich's disease thus far recorded,<sup>11</sup> (including the

<sup>10</sup> This does not include Dr. Smith's case.

<sup>11</sup> Abstracts of this article will be found in Ormerod's Digest.

case reported by Kahler and Pick) in six there was found sclerosis, not only of the posterior columns, but of the lateral as well. In several there was sclerosis of anterior columns.

Of these seven cases the condition of the tendon-reflexes was, unfortunately, noted in only three; in all three the patellar reflex was absent, though there was lateral sclerosis as well.

How are we to explain the absence of all symptoms of lateral sclerosis in these cases on one hand, and on the other hand, of the presence of the knee-jerk in exceptional cases of ordinary tabes, and of the exaggerated jerk in Seeligmüller's cases and mine? The key to this question I believe is given by the autopsies of other cases of systemic spinal disease, not Friedreich's, in which a combination of systemic lateral and posterior sclerosis existed. An excellent digest<sup>12</sup> of these cases has also been made by Ormerod, who has collected twenty cases in all. Of these the patellar reflex was noted as lost in eight and exaggerated in six cases, reported by Strumpell (two cases), Westphal (one case), Raymond (one case), Ralasin (one case), and Déjérine (one case). Of these the most instructive was Déjérine's.<sup>13</sup> The symptoms were those of tabes, namely: slight locomotor, but marked static ataxy; *exaggeration of patellar reflex; ankle clonus; paresis of legs; anæsthesia and analgesia of the legs, distributed in patches.*

Death from broncho-pneumonia. At the autopsy there was found chronic posterior spinal meningitis, atrophy of posterior nerve roots and cutaneous nerves, sclerosis of lateral columns in lumbar and dorsal regions. This sclerosis was wedge-shaped, the base reaching the periphery and occupying the posterior part of the lateral columns, but stopping before reaching the posterior horns (direct cerebellar and crossed pyramidal tract?). The posterior columns were sclerosed the whole length, *excepting in the lumbar enlargement*, which was nearly unaffected.

In the other four cases, all of which, however, presented more decided spastic symptoms, the disease of the posterior columns did not reach the lumbar enlargement. These cases, therefore, support Westphal's opinion, based on his one case where the spastic symptoms were present, and several other cases where they were not—that if the posterior sclerosis involved the lumbar enlargement, the lateral sclerosis was manifested by paresis only, without rigidity, and the patellar-reflex is absent, but if the posterior sclerosis did not extend into the lumbar enlargement, the symptoms of lateral sclerosis predominate.<sup>14</sup>

If the case of Mary D. (the subject of this paper), is properly classified as one of Friedreich's disease, we may assume that the disease has not to any great extent involved the lumbar enlargement; and thus explain the fact that the patellar-reflex is not abolished. Finally, the exaggeration of the latter may be owing to the same conditions which cause an increased patellar reflex in transverse myelitis when the lesion is above the lumbar enlargement; or, if we suppose the same anatomical changes to be present which were found in the six autopsies of Friedreich's disease mentioned above, it is possible that the lateral columns are slightly affected. This would account for whatever amount of paresis is present.

## REPORT ON MEDICAL CHEMISTRY.

BY WILLIAM B. HILLS, M.D.

### ACTION AND METAMORPHOSIS OF SOME SUBSTANCES IN THE ANIMAL ORGANISM IN RELATION TO DIABETES.

K. Albertoni,<sup>1</sup> finds that acetone is not injurious, and even in large doses produces only intoxication. When given to healthy persons in larger doses than three cubic centimetres it is passed unchanged. When alcohol, glucose, or butyric acid was given to dogs or rabbits, neither acetone nor aceto-acetic acid could be detected in their urine. Isopropyl alcohol is partly converted into acetone, partly passes unchanged. Ethyl aceto-acetate or aceto-acetic acid produce nothing like diabetic coma, but sometimes cause the urine to become albuminous. Levulinic acid causes prostration and rapid death; its formation may possibly be the cause of the sudden death sometimes occurring from diabetes.

### CHANGES IN THE CHEMICAL COMPOSITION OF CERTAIN SECRETIONS DURING CHOLERA.

The results of investigations made by G. Pouchet<sup>2</sup> are the following. In cases of cholera, the bile collected very shortly after death is colorless and of a gelatinous consistency, and contains a large proportion of water. The greater part of the solid matter consists of albumin and mucin, but leucine, tyrosine, and glucose are always present, together with fat globules, crystals of fatty acids and cholesterol. The bile also contains products of the decomposition of the bile pigments, which oxidize and reproduce the color when exposed to the air after removal of the albuminoids.

The vomitus frequently contains constituents of the bile.

The alvine ejections are very watery and almost colorless. They contain a relatively large proportion of urea and sodium chloride, especially the latter. They contain the products of the reduction of bile pigments, but are almost invariably free from skatole. Aptomaine can be extracted with chloroform. The urine during the period of reaction contains a larger proportion of organic matter, especially urea, and a smaller proportion of inorganic salts. Sulphates are present in somewhat higher proportion with respect to the amount of urea, but the quantity of sulphur eliminated in the form of sulpho-acid is very small, and, in many cases *nil*. The quantity of sodium chloride present is only one-tenth the normal amount, and the proportion of phosphates, especially earthy phosphates, is also diminished. Amongst substances not normally present, the urine contains bile salts in variable quantity, albumen in somewhat large proportion (5-9 grams per litre), glucose, often in very small quantity, and a peculiar albuminoid. The urine contains a very small proportion of a fixed alkaloid, which does not resemble that extracted from the alvine ejections.

The blood serum contains a relatively large proportion of bile salts, and in one case it gave the chemical and spectroscopic reactions of bile pigments.

### A NEW LABORATORY SUBSTANCE IN THE URINE.

E. Kulz<sup>3</sup> has discovered in the urine of diabetic pa-

<sup>1</sup> Brain, July, 1885.

<sup>2</sup> Journal of the Chemical Society, London, May, 1885, page 576, from Compt. rend., 100, pages 226 and 302.

<sup>3</sup> Zeitschrift f. Biol., 33, page 165.

tients taking chloral hydrate a levorotatory body which is not identical with other levorotatory substances which have been described as existing in urine. Analysis gave a formula for hydroxybutyric acid. But, as it does not agree in properties with any of the hydroxybutyric acids known, he has assigned to it the name pseudohydroxybutyric acid. In fifty-two cases observed, the acid occurred only in the urine of the most severe, and in those which at the same time gave the ferric chloride reaction. The acid itself does not give a color reaction with ferric chloride. The author suggests that it may account for the lower percentages of sugar sometimes indicated by the polarimeter than by titration with Fehling's solution.

W. Müller<sup>4</sup> has made investigations to discover if possible the cause of the disagreement between the above-mentioned methods for the determination of sugar, and went so far as to discover that levulose was not the cause of the discrepancy, and to conclude that a levorotatory substance of an acid nature was present in many diabetic urines. Becoming aware of Kulz's discovery, he abandoned further researches on the subject. The presence of hydroxybutyric acid in a case of diabetes mellitus has also been proven by Minkowski.<sup>5</sup>

#### DETECTION OF SUGAR IN URINE.

In testing urine for sugar with copper solution, the blue coloration frequently disappears and passes into yellow. C. Giacomo<sup>6</sup> finds that neither coloring matter, gum, albuminoids, nor extractive matters cause this change, as, after their removal by means of animal charcoal and lead acetate, the sugar reaction sometimes fails; if, however, an alcoholic extract of the urine extract is treated with concentrated alcoholic zinc chloride, filtered and evaporated after forty-eight hours, then the presence of sugar will be indicated by the copper solution. It is the creatinine, so removed, which prevents the reduction of the copper salt by the sugar, as it reduces the copper salt and combines with the cuprous oxide produced to form a white granular powder soluble in alkalis. This reaction is so delicate that 1/1000 of creatinine can be detected. The sugar reaction only takes place when all the creatinine present has combined with cuprous oxide; so that in the presence of creatinine a larger quantity of copper sulphate is required, and Trommer's test requires to be so modified that ten or twelve drops of tartaric acid, as much copper sulphate, and an excess of potassium hydrate are added to the urine.

#### DETERMINATION OF CHLORINE IN THE URINE.

Chlorine in urine cannot be estimated directly by Mohr's method, since uric acid, coloring matters, and other urinary constituents are also precipitated, and the results obtained are therefore too high. W. Zuelzer<sup>7</sup> recommends the following process: 10-15 cc. of the urine are acidulated with nitric acid and the chlorine precipitated with silver nitrate; the silver chloride is removed by filtration, and dissolved in ammonia; from this solution the silver is precipitated by colorless freshly-prepared ammonium sulphide, or better, potassium sulphide, the excess of sulphide re-

moved by cadmium nitrate, and an aliquot part of the filtered liquid acidulated with nitric acid, neutralized with calcium carbonate, and titrated by Mohr's method.

#### TOXICOLOGY. — NICKEL AND COBALT.

F. Gürkens<sup>8</sup> states that nickel salts, like those of mercury and arsenic, when absorbed into the system, set up inflammation in the glands of the intestinal tract. Nickel acetate acts with much greater energy, when injected subcutaneously, than when taken through the stomach, as in the latter case, absorption of the poison is largely prevented by the formation of insoluble nickel compounds.

Stuart<sup>9</sup> has studied the action of sodium nickel citrate and the corresponding cobalt compound. In rabbits, both metals pass into the bile, intestinal secretions and urine. The latter is colored brown by cobalt compounds. The cobalt separates as a purple phosphate when the urine undergoes putrefaction.

#### NITRO-GLYCERINE.

According to M. Hay<sup>10</sup> the poisonous action of this compound cannot be explained by the action of its constituents. The symptoms are similar to those produced by amyl and potassium nitrites. The author found that, of the three NO<sub>2</sub> groups present in nitro-glycerine, only one is removed by the action of alkalis as nitrate, the other two combining with the alkali as nitrite, whilst the oxygen set free oxidizes the regenerated glycerine. An alcoholic nitro-glycerine solution reacts rapidly in this sense with an alcoholic sodium hydrate solution with development of much heat. The formation of nitrite, however, occurs even on digesting at 40° an aqueous solution of nitro-glycerine (1:8000) with a little sodium hydrate (0.2 per cent); the reaction being complete in about ten minutes. Blood at the temperature of the body acts similarly; the blood becomes chocolate colored, as is the case when it is exposed to the action of amyl or potassium nitrite. Spectroscopic observation reveals the methæmoglobin band. Reducing agents reproduce the red color of hæmoglobin, as in the case of the nitrites above mentioned. Hence nitro-glycerine acts by its conversion into nitrite.

#### BRUCINE.

T. Lauder Brunton<sup>11</sup> has made some experiments with pure brucine, and concludes that it has a convulsant action resembling that of strychnine; but the action is not only weaker in itself but is so much lessened in the case of mammals by the rapid elimination of the poison, as to give rise to no symptoms when the brucine is taken by the mouth. Its convulsant action is shown very distinctly when the brucine is injected in solution into the abdominal cavity, so that it is rapidly absorbed, and the whole or nearly the whole of the quantity administered is able to act upon the organism, there being no time allowed for its excretion. When it is taken into the stomach on the other hand, excretion appears to go on *puri passu* with absorption; there is no large quantity of brucine at any one time

<sup>4</sup> Journal of the Chemical Society, London, June 1885, page 767, from *Pflüger's Archiv*, 35, page 76.

<sup>5</sup> *Chemisches Centralblatt*, 1884, page 106.

<sup>6</sup> Journal of the Chemical Society, London, June, 1885, page 767, from *Chemisches Centralblatt*, 1884, p. 185.

<sup>7</sup> *Berichte der deutschen chemischen Gesellschaft*, 1885, p. 320.

<sup>8</sup> Journal of the Chemical Society, London, June 1885, page 681, from *Chemisches Centralblatt*, 1884, page 14.

<sup>9</sup> *Berichte der deutschen chemischen Gesellschaft*, 1885, page 161, from *Arch. f. exp. Pathol.*, 18, page 14.

<sup>11</sup> Journal of the Chemical Society, London, March 1885, page 143.

in the blood, and the animal does not suffer. The difference between the effects of the two appears therefore to be one of degree rather than of kind, and to be chiefly dependent on the more ready elimination of brucine. The latter, like strychnine, produces death by convulsions and not by paralysis, but like curara, it is innocuous when taken into the stomach though fatal when injected under the skin.

#### ARSENIC.

For the estimation of arsenic in judicial cases, H. Beckurts<sup>12</sup> recommends the following new method founded on numerous experiments made by Pelmt and himself. The substance to be examined is reduced to small pieces when necessary, and mixed to a thin paste with 20-25 per cent. hydrochloric acid, and about twenty grams of a four per cent. solution of ferrous chloride. The mass is then distilled at the rate of about three cubic centimetres per minute, until about one-third has passed over. Substances containing much water are previously evaporated with sodium carbonate; or a more concentrated hydrochloric acid may be used. If not too much arsenic be present, all goes over in the first distillate; otherwise 100 c.c. more hydrochloric acid are added, and the distillation is repeated. The presence of ferrous chloride reduces the volatility of mercury, antimony, and tin to a minimum. The distillate, after dilution with water, can be examined directly in Marsh's apparatus. Quantitatively the arsenic can be precipitated as sulphide, or as the magnesium salt, after oxidation and removal of excess of acid by evaporation, or finally volumetrically after neutralization with alkaline carbonate. By this method the whole of the arsenic from arsenious and arsenic acids passes over. The sulphide is largely decomposed by a first distillation, and a second distillation increases the amount of arsenic carried over. Of metallic arsenic, the oxidized portion goes over entirely; of the unoxidized portion a little only passes over.

Beckurts<sup>13</sup> has experimented with 10 per cent. and 15 per cent. hydrochloric acid, and with 19 per cent. sulphuric acid with reference to their employment in Marsh's apparatus. Drying tubes charged with calcium chloride, with and without stick potash, were used. He found that the mirror appeared in much less time with the 15 per cent. hydrochloric acid than with the sulphuric acid; also that the employment of the potash is unnecessary.

The author states that arsenic can be perfectly removed from hydrochloric acid by fractional distillation with the addition of ferrous chloride. The more concentrated the acid, the more readily does the arsenic distil over in the first portions. When acid of 30-40 per cent. strength is distilled, the first 30 per cent. contain the whole of the arsenic, the next 60 per cent. portion is free from arsenic; a 20-30 per cent. acid, free from arsenic, is thus obtained.

#### CARBONIC OXIDE.

A. P. Fodor<sup>14</sup> describes a modification of Fodor's method for the detection of carbonic oxide. One or two cubic centimetres of the blood to be tested is placed in a shallow beaker, which is floated in a porcelain dish full of water, the beaker being kept in a vertical position

by means of three perpendicular brass wires which carry above a watch glass containing a little palladium chloride solution. A glass shade is inverted over the beaker so that it stands in the dish of water, and two-thirds of the air in the glass shade is exhausted by means of an india-rubber tube. The water in the dish is then boiled, which causes the coagulation of the blood in the beaker, and the carbonic oxide escapes and reduces the palladium chloride in the watch-glass above. If traces only are present, the reduction does not take place immediately and the apparatus should be allowed to stand for twenty-four hours. In this manner it is possible to detect the presence of carbonic oxide in a single drop of blood.

#### RECOGNITION OF NITRIC ACID STAINS ON TEXTURES.

H. Fleck<sup>15</sup> recommends the following method, when the stains have already been washed with water. The stains must be cut out and heated with a twenty per cent. solution of caustic potash. Xanthoproteate of potassium is formed, and colors the solution deep orange; on diluting with ten volumes of water, filtering and neutralizing with sulphuric acid, yellow flakes separate; these are collected on a filter and treated with ammonia, when a deep orange-red color is produced. These flakes cannot be mistaken for those produced by pieric or styphnic acids, since both these acids are soluble in boiling water. A control experiment should be made with a piece of woolen rag, previously steeped for twenty-four hours in nitric acid.

#### DETECTION OF CYANIDES IN THE PRESENCE OF COMPOUND CYANIDES.

Cyanides, when in the presence of compound cyanides, cannot well be detected by the ordinary methods. It is necessary to find a substance which, whilst freely decomposing the cyanide, will leave the ferrocyanide untouched. According to W. J. Taylor,<sup>16</sup> this condition is fulfilled by hydrogen sodium carbonate. All that is required in qualitative analysis is to distil with an adequate volume of water and an excess of hydrogen sodium carbonate. If the preliminary examination shows the presence of mercury, a few grams of zinc must be added, as mercuric cyanide is somewhat refractory, but is readily decomposed in presence of metallic zinc.

#### PREPARATION OF NON-ARSENICAL SULPHURETTED HYDROGEN.

F. Gerhard<sup>17</sup> recommends a solution of hydrosulphide of magnesium. When this is warmed, a uniform evolution of sulphuretted hydrogen takes place and can be regulated by regulating the temperature. The evolution of gas begins at about 60° and is completed at about 95°. The hydrosulphide of magnesium may be prepared by mixing an alkaline sulphide or sulphhydrate, or even calcium sulphide with a salt of magnesium; the resulting mixture containing a salt of the alkali or alkaline earth, together with the magnesium sulphide. If ammonium sulphide is employed, the gas should be passed through a wash bottle containing weak acid, to neutralize the ammonia gas and the ammonium sulphide which accompany the sulphuretted hydrogen. Calcium sulphide is cheapest, but is liable to be impure and to contain much insoluble matter. If used, it should

<sup>17</sup> *Archiv der Pharmacie*, May, 1885, page 281.

be made by reducing gypsum with carbon. One part is to be mixed with three parts water, and three parts crystallized magnesium chloride. If potassium or sodium sulphides are used, they may be made by saturating a solution of potassium or sodium hydrates in three to five parts of water with sulphuretted hydrogen: to this solution a quantity of magnesium chloride or sulphate, about double the amount of alkali employed, is added.

## Reports of Societies.

### MASSACHUSETTS MEDICAL SOCIETY. SUFFOLK DISTRICT. SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE.

ALBERT S. BLODGETT, M.D., SECRETARY.

JUNE 9, 1885.

Through the courtesy of Harvard College, this meeting of the section was convened in the Hall of the Medical School on Boylston Street.

The Section was called to order at 8.10 o'clock. The chairman being absent, Dr. T. W. Fisher was chosen chairman *pro tem*. The reading of the records of the last meeting was omitted. The following communication was read by the secretary.

#### NORFOLK DISTRICT MEDICAL SOCIETY.

Roxbury, Boston, May 16, 1885.

DEAR SIR,—At the Annual Meeting of this District Medical Society, on May 12th inst., after the society had listened to Dr. H. C. Ernst's able paper upon the subject of "Cholera," and to the ensuing discussion, and impressed with the great importance of the necessity of the purity of this community's Water Supply, upon the motion of Dr. E. P. Gerry, of Jamaica Plain, this society voted:

"That a committee of five members of this District Society be appointed to confer with a similar committee of the Suffolk District, to take into early consideration the impurities of the Boston Water Supply, and to request their co-operation with this District Society in urging upon the Mayor of the city of Boston, the vital importance of promptly using all those means which the law allows to prevent further contamination of this Water Supply and to remedy the contamination that exists."

The following named members of the district were appointed the committee for the above purpose:

Chairman, Dr. E. P. Gerry, Jamaica Plain.  
Dr. A. H. Nichols, Roxbury; Dr. J. H. Streeter, Roxbury;  
Dr. H. C. Ernst, Jamaica Plain; Dr. C. F. Withington, Roxbury.  
Respectfully,

GEORGE D. TOWNSEND, M.D., Secretary *pro tem*.

P. S. Dr. Gerry informs me that an official of the Water Department will provide an engineer to aid the committees in any incident inspection of the Water Supply.

The following committee was appointed from this Society to co-operate with the committee appointed by the Norfolk District Medical Society.

Chairman, Dr. George B. Shattuck.  
Dr. C. F. Folsom, Dr. Vincent Y. Bowditch, Dr. A. L. Mason, Dr. H. J. Barnes.

Before the presentation of the regular papers of the evening, Dr. E. B. KELLOGG, by permission, exhibited a fetal monster which had been born a few hours before the meeting, and gave the following history of the case:—

Mrs. H., aged thirty-four, gave birth, June 9th, inst., to a boy, after normal labor of about sixteen hours. Position, the third (right occipito-sacro-iliac.) *Aut-partum* diagnosis: hydrocephalus. The speaker being called away, Dr. S. C. Thayer kindly delivered the child. There was considerable hemorrhage. The placenta was excessively large, friable, lobulated, with large cellular

cavities. Portions of it resembled calcareous degeneration. It was adherent and had to be removed piecemeal by the fingers. The amniotic fluid was large in quantity and floccy in appearance. The child breathed for thirty minutes after birth.

The entire areolar texture of the body was uniformly oedematous and of a dark purplish hue.

The history of the case is meagre. The father is Irish, the mother, French. She admitted taking, during the early stages of pregnancy, large quantities of "cotton root-bark and ergot," prescribed by a "practicing druggist," who informed her that it would surely "bring her 'round all right.'" She had procured one abortion. I had delivered her twice, and the first living child was born, except the head while the mother sat upon the water-closet. Crawling into her bed with the child's body protruding from the vagina she thus remained from 8.30 to 11.30 p.m., when I was called, I delivered the after-coming head. Child asphyxiated. Adherent placenta. Second living child delivered after normal labor, lived only two weeks and died with symptoms of congenital syphilis. Again adherent placenta. No obtainable syphilitic history.

The following is a report of the character of the fetal monstrosity, kindly furnished by Dr. Gannett:

The specimen is that of a male fetus, evidently at full term, well nourished and well developed except for the following appearances about the head and neck. The face is flattened and does not project beyond the anterior line of the body; the face, and anterior surface of neck and body being in the same plane. The neck is short and wide. The tissues forming the scalp posteriorly and laterally and those covering the back of the neck are greatly thickened and boggy, forming a sort of hood for the back of the head, which hangs in a fold reaching to the spines of the scapula. That portion of the covering of this appendage formed by the scalp, is covered with hair; the rest is free from hair. The tumor extends anteriorly, on the top of the head, as far as the middle line of the skull.

The mass is freely movable and quite boggy to the feel. A vertical section through it, shows it to be formed externally of a well-formed skin of the usual thickness, beneath which and forming the mass of the tumor is a loose connective-tissue meshwork enclosing spaces, which vary in size from a pin's head to a large English walnut. Where the tumor is thickest these cavities are the largest, on the borders they are the smallest. The contents are a thin clear fluid, resembling lymph. A microscopical examination showed the cavities to be lined by a thin, flat endothelium, hence they are to be regarded as lymph-spaces.

The skull, together with its periosteum, as well as the vertebral column with its arches, are in every respect well formed and in no way vary from the normal, so far as size, shape or development are concerned.

The tumor is formed by a tissue occupying the seat of the subcutaneous connective-tissue, representing in its structure a cavernous tissue, that is, a series of cavities the walls formed of connective tissue, lined by a thin, flat endothelium and containing lymph.

The tumor is then a *Cavernous* Lymphangioma involving the subcutaneous connective-tissue of the scalp posteriorly and of the back of the neck.

Dr. J. W. ELLIOT showed an ovarian cyst which he had removed by laparotomy on the previous day at the Free Hospital for Women. The cyst was milky-ular and about the size of a child's head. It contained

two quarts of almost clear fluid. Its relations to the fallopian tube and peritoneum indicated that it was without doubt a cyst of the broad ligament. The cyst wall was somewhat thicker than usual, and on the inner surface near its base was a mass of *papillary growth*.

Dr. Elliot thought the specimen might interest the society, because Mr. Doran, an assistant of Sir Spencer Wells, in a recent work on the pathology of ovarian tumors had advanced the idea that the papillary growths have their origin in the broad ligament. Certainly the specimen at hand supports Mr. Doran's theory.

As the papillary tumors are malignant, this must revolutionize the old idea of treating cysts of the broad ligament by tapping. The specimen was instructive in another way in that a papillary growth was beginning in a small tumor and would in a short time have become incurable, on account of its malignancy. Dr. Elliot thought the lesson to be learned was to urge *early operations*.

The patient had been almost completely disabled by this small tumor. The operation was exceptionally simple, lasting about fifteen minutes. Recovery was rapid.

Dr. F. H. HOOVER exhibited a new electric accumulator and the corresponding apparatus for the production of incandescent electric light as perfected by Dr. Felix Lemon and Mr. Arthur Vesey of London, and manufactured by Weiss and Son. It is fully described in a recent number of the *Lauret*.

The appliance is very small and compact, so that it can be carried in the coat pocket; and the lamp is arranged on an extensible hand-piece, so that it can be placed in the mouth, nose, vagina, rectum or other accessible parts without danger of injury to the most delicate organs.

Dr. W. N. BILLARD read a paper entitled

#### A CASE OF PROGRESSIVE MUSCULAR ATROPHY.

With presentation of the patient.<sup>1</sup>

Dr. MORTON PRINCE showed a patient with marked symptoms of progressive muscular atrophy, described at page 371 of *JOURNAL*.

Dr. W. EVERETT SMITH, of Framingham, read a paper upon

#### HEREDITARY ATAXIA, WITH SIX NEW CASES.<sup>2</sup>

and presented one patient who was afflicted with this rare form of ataxic disease. Dr. Smith also showed microscopic sections of the spinal cord, and explained the distribution and character of the degenerative lesion.

Dr. JAMES J. PUTNAM described the lesion found in the specimens of the cord sent to him for examination as consisting principally in a combined sclerosis of the posterior columns and the crossed pyramidal tract, both its anterior and lateral portions, with almost complete destruction of the nerve-fibres in the posterior nerve-roots. There was, besides, a considerable degree of degeneration of the gray matter, and slight affection of the motor nerve-roots. The anterior ganglion cells were greatly reduced in number, and many of those which remained showed various marked signs of disease. The walls of the arteries in the diseased portions, and the central longitudinal arteries as well, were greatly hypertrophied.

The changes, on the whole, were rather of the nature of degeneration than that of active inflammation; or at least the signs of active, primary growth of the connective tissue were not so marked as in some other form of sclerosis. The membranes were thickened over the posterior and lateral columns. The specimens were anatomically interesting also, on account of the presence of a small, well-formed supplementary canal in the median line, a short distance below the principal canal, and, like it, blocked with round cells. Dr. Putnam had seen a boy and girl with this disease in marked form, the only children in an Irish family, in which, according to the mother's account, no other neuroses had been noticed. Vertigo had been from the first a marked symptom.

These cases were seen many years ago, and the knee-jerk had not been tested, but the plantar reflex was noted as greatly exaggerated, so much so, that in one case the attempt to walk with bare feet on stone or gravel brought on muscular contractions, which, for a few moments, made locomotion impossible. Sensibility was essentially normal. He had also seen two separate cases which he believed to be of this type, although no others of the family were affected.

Dr. SEGUI, of New York, said:—You are very kind in calling on me in this way, and I have listened with great pleasure and profit to Dr. Smith's able paper, and have appreciated the opportunity of hearing his very interesting statements. All I could say in addition would be to give a summary of the cases I have seen of this tolerably rare disease, and I will simply read a table, giving the general symptoms, such as those published in the April number of *Brain* of this year.

I have seen two families affected with this disease. In only one of them was there any hereditary neurotic element. In each family there were three children affected. In one, three out of five, and in the other three out of nine.

The first family, in which there were three out of five, were living in New Jersey, and the cases were first brought to me in 1877. I saw two of them at that time, and went out of town a few days ago to examine the three survivors. The first was Lizzie, who manifested the symptoms at four years of age, beginning with a weakness of the neck. She then presented ataxia of the arms and legs, accompanied by the "Romberg" symptoms. There was no true paralysis at that time; the legs were simply weak, and the tendons Achillis tense. There was no tremor. I saw her about a week ago, twenty-two years after the commencement of the symptoms; she was unable to stand, and was sitting in a chair, with a curvature. The legs were very ataxic, and the tendons Achillis tense; there was a tremor in the neck; she had jerking in the legs, similar to Dr. Smith's patient. These symptoms were noticeable while sitting in a chair; her grasp was very good, twenty-one or twenty-two degrees on the dynamometer. There was the slightest possible degree of anesthesia, the sole reflex was very much exaggerated, the spinal column deviated to the left. There was also a little forward curvature, the speech slightly jerky, the special senses normal, and the cerebellum normal.

The second case in that family was ten years of age when the walk was noticed to be peculiar. He died in 1883 through an accident not ataxic. There were "Romberg" symptoms, chewing and swallowing were

<sup>1</sup> Vide p. 369 of *Journal*.

CASES TABULATED TO MATCH DR. ORMEROD'S TABLE IN *Brain*, 1884, pp. 120 to 131.

Designation.	Age and symptoms when first seen.	Duration of disease when first seen.	Ataxic symptoms: gait, lower and upper extremities; head and neck. Romberg's symptoms.	Motor System. (a) True Paralysis. (b) Spasms. (c) Contractures. (d) Tremors. (e) Chorea. (f) Chorea musculi.	Sensory symptoms: Pains, anæsthesia, etc.	Tendon and Skin affectus.	Spinal Column.	Organs of Speech: Lips, Speech.	Special Senses.	Visceral and Vaso-Motor Functions.	Cerebral Functions.
Lizzie K. Dr. Sequin.	Yrs. 4. Ankle weak.	14 yrs. 22 yrs. Living in 1885.	Ataxia of arms and legs. Romberg's symptom present. Cannot stand; legs parietic and ataxic; legs parietic.	No true palsy. Legs parietic; tendo-achilles tense. Tremor only in neck while writing. No chorea. Jerking of legs. Grasp R. 21, L. 22.	Occasional cramps in legs. No pains or numbness. Slightest anæsth. felt.	Sole reflex exaggerated. No patellar reflex.	Sclerotic Left; Torso lumbar.	Jerky speech. No chorea.	Normal.	Normal, except cold feet.	Normal.
Lindley K. Dr. Sequin.	10 Walk peculiar.	5 years. Died 1886, six years later.	Ataxia of arms and legs. Romberg's symptoms present.	No true paralysis. No tremor, chewing and swallowing difficult. Jerking of legs. Chorea-form movements of body in speaking.	None observed.	No patellar reflex.	Bent over near end of life.	Speech thick and slow.	Normal.	Maniacal at the last.	
Nettie K. Dr. Sequin.	7 Peculiar and lateral curvature.	8 years or more. Living 1885.	Ataxia of arms and legs. Romberg's symptoms present.	No true paralysis. (Legs weak). No tremor. Tendo-achilles a little tense. Grasp R. 4, L. 12.	Nerve numbness, or sharp pains.	No patellar reflex.	Cervico Sclerotic to Right.	Normal.	Normal.	Normal. Cold feet.	Normal.
J. H. Dr. Sequin.	7 Weakness of legs.	11 years.	Ataxia of arms and legs. Romberg's symptoms present.	No true paralysis. No tremor. Grasp R. 37, L. 41.	Nerve numbness. Some sharp pains in spots like needle thrusts.	Not noted.	Not noted.	Speech normal, atrophy of the optic nerve.	Partial atrophy of the optic nerve.	Normal.	Normal.
M. H. Dr. Sequin.	15 Difficulty in walking.	17 years.	Ataxia of arms and legs.	Paralysis of legs. Chorea. Tremor of arms and neck, and face in speaking.	Slight anæsth. of feet, legs and fingers. No sharp pains; but "growing pains."	Not noted.	Not noted.	Speech thick and slow; not syllabic.	Sight is dim.	Normal.	Normal? (Silly manner.)

result, as Dr. Clark states. He had choreic symptoms in speaking. He was bent over a great deal towards the end of his life, special senses were normal, was insane and had prolonged screaming spells from apparent cause.

Netty was affected at the age of seven years, and showed lateral curvature, for which she was taken to Philadelphia, where I saw her for the first time, a year after the beginning of the disease. Her legs Achilles were both tense, she never had numbness or sharp pains, her speech was normal, also the special senses. The two survivors I saw last week. The other family consisted of nine members of whom three died at the age of three or four years, of unknown diseases. One sister had the same disease; I saw her, she died in consequence of confinement. The first patient of this family I saw in 1879, at my age, who stated that the first symptoms began at the age of seven years with weakness of the legs and ataxia in the arms and legs. The grasp was forty-seven. This patient had numbness and occasional sharp pains like needle pricks, spinal column normal, tongue ataxic, normal cerebral functions. I saw the second patient at home; was unable to walk, and had been a public beggar many years. His symptoms had begun at the age of seven, with choreic tremors in the neck and face. There were also present in the family observed by Dr. K. There was some anæsthesia of the legs and arms, speech was slow, his manner was silly, but his intelligence was fairly preserved. On account of the clarity of his speech he had been arrested several times by the police for drunkenness.

In a summary I may say that a striking peculiarity in these cases of mine has been the absence of marked tremor. In one or two cases the symptoms were those pointed out by Dr. Putnam. I have had opportunity to examine one of these cases after death, but I will not engage the attention of the society at longer time.

My friend Dr. Starr intrusted me with two specimens to present to the society. They will be pretty

clear, I think, to the naked eye. You will notice the singular appearance of the surface of the spinal cord; I will pass them round for your observation.

The Chairman said:—Owing to the lateness of the hour, the discussion of the able papers presented this evening must now be suspended. The society has listened with great interest to Dr. Sequin, and a motion to adjourn will now be in order.

Adjourned at 10.20 o'clock.

#### MASSACHUSETTS MEDICAL SOCIETY. COUNCILLORS' MEETING.

A STATED meeting of the Councillors was held at the Medical Library, Boston, on Wednesday, 7th inst.

The meeting was called to order by the President, Dr. C. D. HOMANS, at 11 o'clock, A.M.

The following were appointed delegates to other medical societies:—

Vermont Medical Society.— Drs. S. W. Abbott, of Wakefield; E. P. Hurd, of Newburyport.

New York Medical Society.— Drs. J. L. Sullivan, of Mahlen; L. R. Stone, of Newton.

New York State Medical Association.— Drs. H. W. Williams, of Boston; G. E. Francis, of Worcester.

In accordance with the recommendation of the Committee on Membership and Resignations, three Fellows were allowed to retire, and seven, who had lost their membership under By-Law VI, by removal from the State, were dropped from the roll.

It was voted that the town of Stoughton be transferred from the Norfolk to the Plymouth District, though contrary to the unanimous report of the Committee which had been appointed to consider the question.

The following amendment to the By-Laws was passed, and referred to the Society for concurrence:—

In By-Law XIX, line 20, page 15, insert the words

"five in number, who shall also act as a Committee on Finances;" and omit the words, in lines 21 and 22, "a Committee on Finances."

#### MEETING OF THE SOCIETY.

An adjourned meeting of the Society was held at 12.30 P.M. at the same place and on the same day.

It was voted to concur with the Councillors in the above-mentioned amendment to By-Law XIX., and also in the following amendments passed by the Councillors in June last:—

By-Law XX., lines 14 and 15, instead of the words "Thursday before the last Saturday of September and of February," read "third Thursday of September and of December."

By-Law XX., lines 31-33, omit the words "provided, however, that the whole amount paid to any one Board shall not exceed the sum of sixty dollars for any single year."

By-Law XXIX., line 29, omit the words "a Committee, who shall report the same to."

#### A "HOUSE EPIDEMIC" OF PNEUMONIA IN SWEDEN.

DR. FR. RUDBERG gives a brief account in the *Eira* of an epidemic of pneumonia occurring at the end of last year in a workmen's barrack at Sandarne, near Söderhamm, in Sweden, where there are five of these barracks situated in a row at a distance of a couple of hundred feet from one another on a piece of sandy soil near a pine wood. The epidemic was confined to one of these barracks, there only being a single case in the remaining four at the same time, and very few in the surrounding districts. This building was constructed of wood, and had sixteen rooms arranged in two stories, there being a common porch to every two rooms. Each room was occupied by a separate family. The total number of inhabitants was seventy-eight, of whom forty-seven were over fifteen years, and thirty-one under that age. The first case occurred on November 16th, in a boy of eight; subsequent cases occurred on November 27th, and December 1th, 7th, 11th, 14th, 16th, 19th, and 20th. Of these there were four males and five females, one boy and one girl being under ten, but all the rest between twenty and forty. Six cases occurred in the lower story, and three in the upper. The disease appeared to have no tendency to pass from one room to the adjoining one, or even to another room on the same story; and in no case was more than one inmate of a room affected; but one woman living at a distance, who occasionally visited some of those who had the disease, was attacked by it herself on December 11th. It should be stated that there was plenty of intercommunication among the families. The writer does not mention any of the clinical characters of the epidemic.—*Lancet*, Sept. 19.

Dr. Murrell advises that every physician keep an antidote bag, which should contain every drug and instrument needed in the ordinary cases of poisoning. It should always be kept filled and ready for use; so that, in case of emergency, the doctor could take it along or send for it, and not be compelled to look for stray bottles or instruments at a time when a life may depend upon a minute.

## Medical and Surgical Journal.

THURSDAY, OCTOBER 15, 1885.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly, by CUPPLES, UPHAM & CO., Boston. Price, 15 cents a number; \$5.00 a year, including postage, to subscribers in the United States and Canada. Foreign subscribers are charged the postage in addition.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.*

CUPPLES, UPHAM & COMPANY,

283 WASHINGTON STREET, BOSTON, MASS.

#### THE RELATION OF PHYSIOLOGICAL CHEMISTRY TO THE PRODUCTION AND CONSUMPTION OF FOOD.

THE Malthusian theory has never had much terror for the average inhabitant of the United States, nor have we yet felt called upon to consider the propriety of suggesting the tonic of "penny dinners" for our public school children that they may be equal to their tasks. In fact the wastefulness of American households of all classes is proverbial—a wastefulness arising quite as much from ignorance as to the best ways of preparing and combining food, as from reckless purchasing—and there is no doubt that a French or German family would live, and live well, upon what an American family of the same class throws away. The time is coming, however, and is not so far off in our thickly-settled Eastern States, when the secret of getting ahead and of getting something out of life besides an opportunity to labor for its support, will be found to lie in a truly scientific selection and combination of foods. In Germany, the Government has employed Professor König to work up this subject and furnish the people with practical suggestions.

Mr. Edward Atkinson, Chairman of the Section on Economic Science and Statistics, delivered an address before the American Association for the Advancement of Science, at its recent meeting, on the "Application of Science to the Production and Consumption of Food;" in which we find statistical statements calculated to impress the reader with the importance of a local application of tabulated dietaries furnished by Prof. W. O. Atwater, of Middletown, Conn., under the head of a "Standard Ration."

If we accept as facts the statement that "the average product to each person in this most prosperous country, measured in money at the point of final distribution for final consumption, does not exceed fifty to fifty-five cents worth per capita, and that our whole accumulated wealth, aside from land, does not exceed two or at the utmost three years' production;" and another statement that "in order to give each person of our present population five cents' worth more per day, we must produce and distribute one thousand million dollars' worth more than our present annual

product;" and still another statement that "if our present population of over 57,000,000 is reduced to the equivalent of 50,000,000 adults, by counting two children under ten as one adult, and then assign to each of the 50,000,000 one egg every two days at the price of one cent each, then the annual value of the product of hens' eggs would be equal to the annual product of gold and silver of all our mines." If these statements are accepted as facts, then it ought not to be very difficult for the most practical and unimaginative mechanic or day laborer to realize the importance and the profit of beginning a true study of food, and of heeding the teachings of a true science of nutrition.

The human machine, as well as any other, requires a certain amount and a certain kind of fuel to accomplish certain results. If that necessary fuel can be provided for twelve cents for which the individual is accustomed to expend one hundred cents, he gains either so much time from the hours of labor or adds so much money to his savings. At present the mere price of food in our country is calculated as constituting sixty per cent of the cost of living, even for those who are fully and continuously occupied on the plane of common laborers. But Professor Atwater attempts to show this class how to maintain themselves in full vigor at a cost of thirty or forty per cent of their ordinary income. There is, undoubtedly, a much wider choice in the ration of food necessary to sustain an adult in full vigor and health than is ordinarily recognized.

In this country all classes consume much more meat than they really require, and many individuals of all classes much more meat than is really good for them. Now protein is the force-producing element of food, and Professor Atwater, in whose laboratory at Middletown the analysis of food products for the exhibition at the Smithsonian Institute was made, shows that a pound of protein in a sirloin of beef at twenty-five cents per pound costs one dollar, whereas a pound of protein in oat meal or corn meal costs twelve or fourteen cents. Chemical investigations show, moreover, that in the oat meal of the Scotch, in the baked pork and beans, the fried fish ball, or the brown bread of the New Englander, and in the corn meal and bacon of the Southern negro, the right proportion of the elements of food are found combined at the lowest cost.

Of the three most important classes of the nutrients of food, protein is the most expensive, costing five times as much as the same weight of the carbohydrates, and nearly twice as much as the same weight of the fats. The exact physiological values of the nutrients in different foods, depending upon their digestibility and their functions and the proportions in which they can replace each other, are in the present state of knowledge, not ascertainable; but protein is physiologically the most important.

Professor Atwater adopts the standard of nutrients in a daily ration for a laboring man at moderate work, of Professor Voit, of Munich, namely: 118 grammes of protein, 56 grammes of fats, 500 grammes of car-

bohydrates: and constructs upon this standard several tables for daily rations at a cost of twelve cents or less, twelve to fifteen cents, fifteen to twenty cents, and twenty to forty-five cents, respectively. The amount and the cost of each article is given. In other tables, taken from the German of Dr. Meinert, the amounts of the three important nutrients in each article is also appended.

It is easy to see from such tables — rudimentary as the knowledge upon which they are based confessedly is — that the purses and stomachs of a large part of our population admit of very great alleviation, and that too without the introduction of a more enlightened cuisine. The physiological chemist has here a noble field before him, in which to labor with the sociologist and the political economist.

#### A MEDICAL STAR CHAMBER.

THE Executive Committee of the committee appointed to arrange for the meeting of the International Medical Congress in America, in 1887, has recently held a meeting in New York City. An editorial in the *Journal of the American Medical Association* contains all the information concerning it that is made public. The little that is vouchsafed us has certainly the merit of exciting curiosity as to what has been left untold.

To prevent all further misunderstanding both at home and abroad, the committee unanimously adopted the following declaration of independence: —

"That the actions of this Executive Committee are final, not being subject to revision, amendment or alteration, by either the Committee of Arrangements or the American Medical Association."

How will the Committee of Arrangements and the American Medical Association like that?

The opinion of Mr. Randall, delivered no longer ago than last May, was urged in support of interference with the original committee for alleged too great independence of action. If of force at that time it is equally good authority at present.

"I might add, in addition," said Mr. Randall, "that the theory that a select committee created by a body with certain defined powers and duties gives any vested rights — so to speak — which places it above or beyond the power of the creating body to review or regulate, is one not only without precedent in parliamentary law, practice or history, but is untenable on any ground of parliamentary principle."

Professor Frederick S. Dennis was appointed Associate Secretary General, and another was appointed Chairman of the Finance Committee. Why another's name should be concealed from an anxious public we can only conjecture. Is the anonymous gentleman too modest to allow his name to appear? Is some nameless individual to assume the expenses of the Congress? Is secrecy necessary as a safeguard against theft, or is the Committee ashamed of its appointment? It must be a very bad choice indeed which can be worse than such ostentatious secrecy. It would seem as

though this branch of the enlarged committee was bound to destroy what little respect was left for the proposed International Congress.

## Miscellany.

### BOSTON DISPENSARY.

THE statistics of this institution for the year ending September 30, 1885, are as follows:—

The number of new patients treated at the central office is 18,246, classified as follows:—

Medical Department.—Men, 2,220; women, 4,461; children, 2,076; total, 8,757.

Surgical Department.—Men, 1,338; women, 659; children, 374; total, 2,371.

Department for Diseases of the Skin.—Men, 635; women, 329; children, 260; total, 1,224. Diseases of the Nervous System.—Men, 345; women, 210; children, 45; total, 600. Diseases of Women.—Women, 407. Diseases of the Throat and Nose.—Men, 396; women, 496; children, 363; total, 1,255. Diseases of the Eye.—Men, 68; women, 113; children, 120; total, 301. Diseases of the Ear.—Men, 104; women, 133; children, 142; total, 379. Diseases of the Genito-Urinary System.—Men, 678; women, 5; children, 2; total, 685. Diseases of the Rectum and Anus.—Men, 66; women, 48; children, 11; total, 125.

Dental Department.—Men, 393; women, 632; children, 917; total, 1,942.

The number of visits made by patients old and new at the Central Office is 35,298, classified as follows:—Medical, 15,559; surgical, 20,739; total, 36,298. The number of new patients treated in the Districts is 12,535, including 238 cases of midwifery. Classified as follows: Men, 2,286; women, 1,620; children, 5,629; total, 12,535. The results of treatment in the District are as follows:—

Discharged, cured or relieved . . . . .	11,273
Removed to Hospitals . . . . .	903
Died . . . . .	343
Remaining under treatment . . . . .	81

Under treatment at last annual report . . . .	12,600
	65

	12,535
--	--------

The number of new patients treated at the Central Office and in the District is . . . . . 30,781

Number of cases of midwifery attended during the year . . . . . 238

Number of cases of midwifery attended since July, 1856 . . . . . 1,115

Whole number of patients since Oct., 1796 . . . . . 301,172

Whole number of patients since July, 1856 . . . . . 782,369

Average daily attendance at the Central Office . . . . . 122

Largest number present any one day, Aug. 7 . . . . . 223

Smallest number present any one day, Dec. 20 . . . . . 11

Number of recipes put up at the Central Office during the year . . . . . 11,715

Number of house recipes . . . . . 33,101

Number of district recipes . . . . . 8,611

Largest number of recipes put up in one day, May 1 . . . . . 226

Smallest number of recipes put up in one day, Oct. 31 . . . . . 58

Number of paid recipes . . . . . 38,349

Number of free recipes . . . . . 3,366

Surgeons: Drs. Charles E. Inches, J. Foster Bush, Samuel J. Mixer and George N. Monks. Physicians: Drs. Robert Disbrow, Joseph P. Oliver, Robert M. Lawrence, John Dixwell, Thomas M. Rotch, Claudius M. Jones, Henry C. Haven, Harold Williams, James J. Minot, George M. Garland, Edward M. Buckingham, Vincent Y. Bowditch, William C. Emerson, Charles G. Weld, Robert B. Dixon, Frederick W. Vogel, Russell Sturgis and Rufus A. Kingman.

Department for Diseases of the Skin.—Physicians: Drs. Francis B. Greenough and Abner Post. Diseases of the Nervous System.—Physicians: Drs. Morton H. Prince and William N. Bullard. Diseases of Women.—Physicians: Drs. Francis H. Davenport, John W. Elliot, F. Howard Lombard and John B. Swift. Diseases of the Throat and Nose.—Physicians: Drs. Thomas A. DeBlois and John W. Farlow. Diseases of the Eye.—Physician: Dr. Charles H. Williams. Diseases of the Ear.—Physicians: Drs. Franklin H. Hooper and George A. Leland. Diseases of the Genito-Urinary System.—Physicians: Drs. George H. Tilden and Francis H. Watson. Diseases of the Rectum and Anus.—Physicians: Drs. Walter J. Otis and William D. Hodges.

Obstetrical Department.—Physician: Dr. Charles M. Green.

Dental Department.—Dentist: Dr. Joseph E. Waitt. District Physicians: No. 1. Dr. Willis B. McMichael. No. 2. Dr. Edward W. Warren. No. 3. Dr. Thomas F. Sherman. No. 4. Dr. James S. Howe. No. 5. Dr. Hayward W. Cushing. No. 6. Dr. George G. Hayward. No. 7. Dr. William F. Temple. No. 8. Dr. Winfred B. Baneroft. No. 9. Dr. Frederick W. Doggett.

Apothecary, Frank H. Clark. Assistant Apothecary, Frederick H. Dudley.

W. H. H. HASTINGS, *Supt.*

## Correspondence.

### RESIGNATION OF DR. HENRY I. BOWDITCH AS VICE-PRESIDENT OF THE PROPOSED INTERNATIONAL CONGRESS.

BOSTON, October 8, 1885.

MR. EDITOR.—Since Dr. J. S. Billings, as General Secretary of the Committee for arranging the International Congress for 1887, informed me that I was selected as one of the vice-presidents of the Congress, I have had no official notice either of my summary displacement by the new committee at its meeting in Chicago (June 21) or of my reinstatement by the same committee (Sept. 3). For this and other reasons to be named, I ask a place in your Journal for the following statement. When urged by some friends to sign the protest made in several cities, by gentlemen opposed to the action taken at New Orleans, I replied, "It would be absurd for me to do so, because the committee has already expelled me from office."

Since that time I have watched with interest the course pursued by the *Journal* of the American Medical Association, and also that of the new committee for the International Congress. I have read with pain the perpetually recurring bitterness and insinuations against all those who had dared to express opinions adverse to the doings of the Association, or those of its new Committee. I was surprised and disgusted while reading the editorials of August 1st, entitled "The International Medical Congress and its Enemies," and that of August 29th, "International Med-

ical Congress of 1887 and the American Medical Association." From these editorials any foreigner reading them would not have the least suspicion that the controversy on the "Code" had any share in the embroglio, at present existing. I wholly deny that those who now disapprove of the course the Association and its Committee have taken, are the "enemies of the International Congress." On the contrary, they are, in my opinion, its best friends.

Notwithstanding my objection to such editorials, I have continued to decline to sign the protest in the hope that, by so acting, I might perchance do something toward the promotion of professional harmony in America.

But the last manifesto of the Committee and gross assumption of despotic power for making all future arrangements for the Congress (*vide* "Executive Committee of the Ninth International Congress," *Journal American Medical Association*, September 3d) convince me that I can remain no longer in the position to which the new committee (as I learn from the journals) placed me without my knowledge or consent at their meeting in September.

That manifesto by the new committee is equalled by nothing in the history of medicine in this country, save the arrogant position taken by the Judicial Council of the American Association, at its meeting in Cleveland in 1883. The Council, through its chairman, declared that the Council "took the responsibility" of requiring every member to sign *annually* the Code of Ethics, or to lose his right to meet his fellows at the gatherings of their Association for the advancement of the sacred cause of Medical Learning!

That decision of the Council was disgraceful alike to the Council as declaring its assumption of power which it did not legally possess, and to the Association for its pusil-

lanimity in submitting, *even to the present day*, to the insult then inflicted upon it, — a so-called scientific and learned body.

To one who looks behind the scenes and knows whose intellectual power, combined with honest but misguided bigotry, has influenced the Council of the American Association, there is no difficulty in understanding the present position of the "Committee for the International Congress."

The same dominant mind governs both. I loathe all such ungenerous and bigoted work, and therefore retire from office in the same public manner that I have been placed there. In declining thus publicly the honor it would confer on me, I am only imitating the example set by the Committee in its intercourse with me.

Respectfully yours,

HENRY I. BOWDITCH, M.D.

P. S. By a singular coincidence, I have received to-day, since the above was in type, from the Chairman and Secretary of the Committee, official notice of my appointment to the office of Vice-President of the International Congress. Upon mature reflection I cannot alter my decision, as above given.

#### ANIMAL VACCINATION.

Boston, October 13, 1885.

MR. EDITOR:—Upon my return from the country my attention was immediately directed to Dr. S. C. Martin's statement in the JOURNAL of last week. With your permission I will prepare a reply for next week's issue.

Very truly yours,

THOMAS WATERMAN.

#### REPORTED MORTALITY FOR THE WEEK ENDING OCTOBER 3, 1885.

95 Massachusetts towns . . . . .	—	48	13	20.84	18.72	8.32	8.32	4.16

The population of the Massachusetts cities in the above report is that of the State Census, of May 1st, 1885.

Deaths reported 1,465: under five years of age 586; principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrheal diseases) 274, consumption 249, lung diseases 106, diarrheal diseases 113, diphtheria and croup 72, typhoid fever 41, malarial fevers 16, whooping-cough 10, scarlet fever six, cerebro-spinal meningitis six, small-pox four, measles two, yellow fever one, puerperal fever one. From malarial fever, New York 10, Baltimore three, Philadelphia two, Providence one. From whooping-cough, New York four, Philadelphia three, Baltimore, Providence and Somerville, one each. From scarlet fever, New York three, Boston two, Philadelphia one. From cerebro-spinal meningitis, New York and Philadelphia two each, Worcester and Fall River one each. From small-pox, New York, three, Fall River one. From measles, New York and Lawrence one each. From yellow fever, Boston one. From puerperal fever, Baltimore one.

One case of small-pox reported in Lowell.

In 115 cities and towns of Massachusetts, with an estimated population of 1,419,999, (estimated population of the State 1,555,104), the total death-rate for the week was 14.06 against 15.03 and 15.76 for the previous two weeks.

For the week ending September 12th in the Swiss towns there

were 28 deaths from consumption, diarrheal diseases 18, lung diseases 11, small-pox three, whooping-cough two, scarlet fever, diphtheria and croup and typhoid fever one each.

The death-rates were: at Geneva 8.1; Zurich 3.9; Basle 21.9; Berne 22.9.

For the week ending September 19th, in the Swiss towns, there were 20 deaths from diarrheal diseases, consumption 17, lung diseases seven, typhoid fever, diphtheria and croup each three, small-pox and whooping-cough each two, erysipelas one.

The death-rates were: at Geneva 13.2; Zurich 2.0; Basle 12.9; Berne 21.8.

In the 28 greater towns of England and Wales, with an estimated population of 8,906,446, for the week ending September 19th the death-rate was 17.1. Deaths reported 2,925; infants under one year of age 779; acute diseases of the respiratory organs (London) 152, diarrheal 183, scarlet fever 49, whooping-cough 46, fever 41, measles 36, diphtheria 32, small-pox six.

The death-rates ranged from 11.4 in Huddersfield to 28.6 in Preston; Birkenhead 20.2; Birmingham 12.7; Blackburn 14.4; Brighton 17.3; Hull 15.7; Leeds 15.3; Leicester 18.0; London 15.7; Liverpool 21.4; Manchester 20.6; Nottingham 17.8; Sheffield 15.7; Sunderland 17.1.

In Edinburgh 14.0; Glasgow 19.1; Dublin 22.9.

The meteorological record for week ending October 31, in Boston, as follows, according to observations furnished by sergeant O. B. Cole of the United States Signal Corps:—

Week ending	Barometer.		Thermometer.		Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM OCTOBER 3, 1885, TO OCTOBER 9, 1885.

BARTHOLO, J. H., assistant surgeon and captain. Ordered from Fort Ringgold, Texas, to Fort McIntosh, Texas, for duty as post surgeon. S. O. 125, Department of Texas, September 28, 1885.

WEST, DANIEL, assistant surgeon and captain. To be relieved from duty at camp at Rock Springs, Wyo., and return to his proper station, Fort Fred Steele, Wyo. S. O. 99, Department of Platte, October 1, 1885.

BLAIR, VICTOR, assistant surgeon and captain. Sick leave of absence further extended six months, on surgeon's certificate of disability. S. O. 227, A. G. O., October 3, 1885.

BISHOP, G. E., assistant surgeon and first lieutenant. Granted leave of absence for one month. S. O. 215, Department of East, October 6, 1885.

STILWELL, WM., assistant surgeon and first lieutenant. Relieved from duty at Fort Niobrara, Neb., and ordered for duty at camp at Rock Springs, Wyo. S. O. 99, Department of Platte, October 1, 1885.

CHAPIN, A. R., assistant surgeon and first lieutenant. Leave of absence extended one month. S. O. 229, A. G. O., October, 7, 1885.

#### OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING OCTOBER 10, 1885.

BROOK, GEORGE A., surgeon. To United States Steamship "Brooklyn."

FITZ, HENRY B., assistant surgeon. To Naval Hospital, New York.

HALL, JOHN H., passed assistant surgeon. Detached from Naval Hospital, Mare Island, Cal., and ordered to the "Hartford."

SWAN, ROBERT, post assistant surgeon. Detached from Naval Hospital, New York, and ordered to the "Brooklyn."

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE FOR THE WEEK ENDED OCTOBER 3, 1885.

BAILLACHE, P. H., surgeon. Detailed as chairman of Board for the physical examination of officers of the Revenue Marine Service, September 28, 1885.

VANSANT, JOHN, surgeon. Order to New Orleans, La., revoked; to proceed to St. Louis, Mo., October 2, 1885.

PURVANCE, GEORGE, surgeon. To proceed to Louisville, Ky., as inspector, October 1, 1885.

GASKAWAY, J. M., surgeon. Detailed as chairman of Board for the physical examination of officers of the Revenue Marine Service, October 3, 1885.

GODFREY, JOHN, surgeon. Order of September 16 amended, to proceed without delay to Louisville, Ky., September 28, 1885.

GOLDSBOROUGH, C. B., passed assistant surgeon. Order of September 16 amended, when relieved, to proceed to Chicago, Ill., October 1, 1885.

HEWIS, FAIRFAX, passed assistant surgeon. Detailed as recorder of Board for the physical examination of officers of the Revenue Marine Service, September 28, 1885. To examine physically, and instruct crews of the Life Saving Service, Third District, in the method of resuscitating the apparently drowned, October 3, 1885.

BANKS, C. E., passed assistant surgeon. Detailed as recorder of Board for the physical examination of officers of the Revenue Marine Service, October 3, 1885.

#### SOCIETY NOTICE.

AMERICAN ACADEMY OF MEDICINE.—The American Academy of Medicine will hold its next annual session at New York, on October 28 and 29, 1885.

#### BOOKS AND PAMPHLETS RECEIVED.

Session of 1885-86. Annual Announcement of the New York College of Veterinary Surgeons and School of Comparative Medicine. New York.

## SIMPLE CATARACT EXTRACTION.

BY HENRY W. WILLIAMS, A.M., M.D.,

Professor of Ophthalmology in Harvard University.

FOR more than twenty years, the influence of von Graefe of Berlin was paramount in regard to the methods of extraction of cataract. After having for a considerable time advocated Waddau's plan, for out-scooping combined with iridectomy; a shallow spoon being passed through the external upward incision and carried behind the lens to effect its evulsion; von Graefe abandoned this method, and substituted therefor a plan of his own, which consisted in making a linear incision, wholly within the limits of the sclera, just beyond the upper border of the cornea, and then doing iridectomy so as to allow of extraction of the lens through a smaller incision than that made in the ordinary flap extractions.

Notwithstanding some obvious objections to this method, the authority of von Graefe caused it to be very generally adopted, almost unquestioned. But experience soon proved, that whereas its immediate advantages had perhaps been over-estimated, dangers almost unknown to other methods were concomitants of this operation. Of these, the most serious was the not very infrequent occurrence of subsequent loss of the non-operated eye, from migratory inflammation caused apparently by the implication of the iris and ciliary body in the scleral cicatrix. For this and other reasons, various modifications were nearly everywhere gradually substituted for von Graefe's method, so far as regarded the place and the form of the incision; though the iridectomy was retained. Within a few months a sudden revulsion of opinion has taken place, leading to a somewhat general abandonment of operative methods which had been so long and so largely in favor.

The number of the *Annales d'Oculistique* for December, 1884, contained an article by Dr. de Wecker of Paris, whose reputation as an operator of ability and large experience is well known. A complete translation of this important communication, on which Dr. de Wecker gives, at length, his reasons for the conclusions he has reached "after having long and carefully studied and submitted to experimental trial all the methods of extraction of cataract," would be interesting to your readers; — but I must content myself with a brief summary. These conclusions, and the operative method now advocated by Dr. de Wecker, are similar to the opinions and practice I have for many years maintained.

From the commencement of 1880 till the end of November 1884, 1,289 extractions were done at the clinique of Dr. de Wecker, in which a corneal section made exactly at the junction of the transparent border of the cornea with the sclera, was adhered to. At first, in the majority of the cases, the excision of a portion of iris was done, because of the fear that patients operated on by the simpler methods might run the risk of glaucomatous complications. But the occurrence of several cases of subsequent glaucoma where an entirely correct iridectomy had been done, shook Dr. de Wecker's confidence that any guarantee against glaucoma was afforded by this means. He therefore came to the conclusion that iridectomy, causing more mutilation of the eye, should not be done, if, with equal

safety in operating, as perfect visual acuteness could be obtained without it, while preserving completely the normal aspect of the eye. *This transition point, he says, we have actually reached.*

Dr. de Wecker goes on to say, that when he advised, ten years since, a return to simple flap extraction, he had already eliminated the alleged advantages of the excision of the iris from an antiphlogistic point of view, and had pointed out, as is now generally admitted, that every complication immediately after extraction is due to infection of the wound; upon which any excision of the iris could have no preventive effect. On the contrary, the preservation of the iris secures a better condition of the corneal section, and affords a guarantee against the entangling of the capsule of the crystalline in the corneal wound, and, as its consequence, the sympathetic inflammation of the other eye. Since the recent works of Knies, Leber and Deutschmann, Dr. de Wecker is disposed to insist much more on the cleanliness of the internal surfaces of the wound, and the influence this may have in preventing sympathetic ophthalmia. "No one can deny," he says, "that cases of sympathetic inflammation after operations were almost unknown in the time of David, Wenzel, Beer and Sichel, and it is indisputable that the appearance of a traumatic ophthalmia migrating from one eye to the other, coincided with the adoption of the peripheral sections and their combination with iridectomy."

"As a means of preventing infection of the wound itself, iridectomy is rather injurious than useful; in the sense that the extent of surface liable to infection is increased and a more direct path for infecting material is thus opened towards the capsule of the crystalline, the ciliary body, and the choroidal lymphatic spaces."

"More recently, it has been admitted, that, with equally good coaptation, incisions made wholly within the limits of the cornea are even more quickly healed than those within the sclera."

"In following attentively the evolution of the operation for cataract in recent times, every one could observe that having gone with von Graefe to the extreme of periphericity of the section it was quickly perceived that this was going too far. Therefore the operators who had adopted the method of this great master retraced their steps, and have more or less resumed the placing their sections within the transparent part of the cornea. But they find, although their incisions are no longer peripheral but are made so as not to extend into the sclera, nevertheless, cases of sympathetic ophthalmia occur from time to time if they continue to combine iridectomy with their corneal sections. This clinical observation teaches, that it is not sufficient to abandon the peripheral incisions; but that it is also necessary, as far as possible, to give up incisions of the iris."

The combination of cocaine anesthesia with instillations of eserine; together with the agglutination of the wound by means of iodoform, is regarded by Dr. de Wecker as of great advantage in the method of simple extraction. "Thanks to the anesthesia which we owe to Koller, the troublesome contractions of the ocular muscles are avoided, prolapse of the iris is not likely to occur, or, if this should happen, it can be easily replaced; the iris remains long under the influence of the cocaine and eserine, and the occlusion of the wound by iodoform prevents the escape of aqueous humor which favors subsequent hernia of the iris."

De Wecker operates as follows: Five, and then three minutes before the operation, a few drops of a solution containing .50 centigrammes of hydro-chloate of cocaine, and 0.002 milligrammes of corrosive sublimate in 10 grammes water, are put into the eye. Using this antiseptic solution he does not bathe the conjunctiva but he carefully washes the edges and surface of the eyelids with a solution of four per cent. boracic and one per cent. salicylic acid: in which solution the dressings afterward applied to the eyes are also to be dipped.

In making the section care is taken that it shall include, as exactly as possible, the upper third of the cornea. The knife, one half the size of that of von Graefe, being entered near the outer sclero-corneal border, is carried steadily across the anterior chamber, being held parallel to the iris, to the point of counter-puncture exactly opposite to the point of entrance, and by the upward and onward movement of the knife a flap of perfect regularity is obtained. As the flap is thus slowly formed the patient feels no pain, and does not contract the ocular muscles, and prolapsus of the iris is not likely to take place; but if this should occur, the capsule is to be opened with the kystistome without regard to the hernia of the iris. Gentle pressure is then made with a finger placed against the lower edge of the cornea, while the upper border of the incision is slightly depressed with the upper lid. As soon as the crystalline begins to show itself in front of the iris, all pressure is discontinued, the lids being kept gently separated. The iris being in place and the pupil quite black, the patient's vision may be tested; after which the wound is to be cemented with iodoform. A hard rubber tampon which had been kept in a solution of carbolic acid is dipped into the powder of iodoform, and a layer of this, one millimetre in thickness is applied over the whole extent of the corneal wound. This process completed, the upper lid is drawn over the cornea, and, without removing any excess of iodoform which may remain at the inner canthus, dressings moistened with the boracic solution are applied over the lids, and these are covered with salicylated cotton and a bandage.

Similar views of this subject were published, a little later, by Dr. Gaderowski of Paris, also an operator of celebrity; and the example of these distinguished men has already been followed by operators of repute, in this country as well as abroad, who until recently had retained strong preferences for the original or the modified method of von Graefe; but who, dissatisfied with the results they had obtained, were ready to welcome the departure which, if not absolutely new, has found new advocates whose opinion has great value.

(To be continued.)

The following subjects were discussed at the International Congress on the Abuse of Alcoholic Drinks, recently held at Antwerp: the effect of legislation on drunkenness; the relation between drunkenness and fiscal measures applied to the trade in alcohol; the influence of temperance societies on the consumption of alcohol, on crimes and mortality in the countries where these societies exist (America, England, Denmark, France, Sweden, Norway, and Switzerland); report on the results of coffee-houses in England; the results obtained in England by "Inebriate Homes." The Congress will meet again two years hence.

## SO-CALLED MYCOSIS FONGOIDE.<sup>1</sup>

BY GEORGE H. TILDEN, M.D.,

Physician, Department of Diseases of the Skin, Boston City Hospital.

*Syn. Beerscheemähnliche multiple Papillargeschwülste der Haut. Inflammatory fungoid neoplasm, Granuloma sarcomatodes cutis, Granuloma fungoides cutis, Sarcoma cutis, Lymphadenie cutane.*

ONE of the twigs on the topmost branch of Alibert's arborescent classification of cutaneous diseases bears the name Mycosis Fongoide, employed by that Dermatologist to designate an uncommon affection of the skin, which has since been described by various authors under half a dozen different titles. An instance of this disease came under my observation at the Boston City Hospital, in August of last year, having been sent to me by Dr. Vincent Bowditch.

The patient was twenty-eight years of age, a man of robust build, whose family history gave no information of importance in connection with his malady, and whose condition had always been one of uninterrupted good health until his twenty-fifth year, when the first manifestations of the disease appeared. These consisted in the development of several small red and desquamating spots, situated about the elbows and attended by intermittent attacks of pruritus, which affected principally the outer sides of the arms, and were a source of much annoyance. The skin, in general, however, retained its normal aspect for several months, at the end of which time there appeared, irregularly distributed over the face, abdomen and arms, many erythematous spots and patches of various sizes and individually of a fugitive character, which were attended and followed by desquamation and severe itching, the latter being aggravated by any exposure of the skin to the air, by the influence of perspiration and by indulgence on the part of the patient in alcoholic liquors. According to his account, there was never anything like the formation of vesicles in connection with these lesions, which always retained their dry and scaly character.

This condition of the skin obtained with periods of remission and relapse, for about a year and a half, the general condition of the patient, meanwhile, remaining perfectly good. It was not until nearly two years after the beginning of the disease that there appeared several small cutaneous nodules of a red color, situated upon the left cheek and throat, the attention of the patient being first called to them by their interference with the act of shaving. Some of these nodules spontaneously disappeared and no others became manifest until two or three months later, when there appeared upon the inner and lower part of the right thigh, a small red papule, which increased with slow and constant growth until it was represented by a cutaneous tumor the size of an orange. In consistence this tumor was moderately firm and its upper surface was denuded of epidermis, of a dirty yellowish color, and exuded a thin fluid, which, upon exposure to the air, readily dried to a thin crust.

Shortly after the first appearance of this growth, there showed themselves in both groins, many papules of a like nature, which remained quiescent for several months, but eventually those in the left inguinal region developed with great rapidity, forming a mass of thickly crowded fungous excrescences of a reddish

<sup>1</sup> Read at the Annual Meeting of the American Dermatological Association, August 27, 1885.

brown color, irregular shapes, lobulated and fissured in appearance, and covered with epidermis, the largest of them being the size of an English walnut. During the six months previous to the time I first saw the patient, numerous lesions in the shape of papules of various sizes had appeared on different parts of the body, more abundantly in and about the axilla and upon the neck and scalp than elsewhere, and many of them had developed into tubercles and some into tumors.

Upon the back of the head there was a large oblong patch of irregular outline, composed of flat tumors, measuring five by three inches in extent, and elevated nearly one-half an inch above the cutaneous level, the surface unevenly fissured and covered for the most part with epidermis. The color of this patch was pale red and its consistence soft and doughy, although at the time of their first appearance, these tumors were, according to the patient's account, much harder than when I saw them. The scalp, with the exception of the area taken up by this group of tumors, was thickly covered with hair.

The forehead presented a collection of several large, flat, red papules, which were combining to form a large circular lesion of slight elevation and covered with epidermis, but of harder consistence than those upon the scalp. Upon the right cheek, near to the angle of the mouth, was a tumor, circular in outline, elevated nearly an inch above the level of the surrounding skin and somewhat larger than a silver half dollar. Its upper surface was slightly convex, deprived of epidermis, of a pink color with shadings of yellow, studded with numerous red points and covered with a thin glaze, which was easily removed by friction or by the influence of warmth and moisture, thus allowing the escape of a reddish fluid, which upon exposure to the air again dried to a thin crust. In consistence this tumor was firm, being much more dense than those upon the scalp, the softness of which approached fluctuation.

Almost surrounding the neck of the patient was a broad collar of a dusky red color and nodulated surface, formed by the coalition of papules and tubercles, extending upwards, as far as the jaw, and below, draping itself with irregular outline upon the breast and shoulders. Just above the elbow joint, on the outer side of the left arm, was a moist tumor, similar to but smaller than the one upon the cheek, and immediately below it was a patch of combined papules and tubercles resembling those upon the neck. Upon the upper part of the back over the apex of the right scapula, on the right thigh below the fold of the nates, on the back of the left thigh and in the right popliteal space, were flattened tumors and groups of tubercles of various grades of consistence and covered with epidermis of a pale red color. There were many papules and tubercles isolated and in groups, in and about the axilla and groins, while the abdomen, thighs and arms were covered with erythematous spots and patches, interspersed with papules and tubercles, which varied in size from that of a small pea to that of a filbert. None of these lesions were pedunculated or connected with the skin by a narrow neck, but all were attached by a base as large or larger than their tops. On the right thigh and in the left groin were tumors which have already been described.

Although they presented much diversity in size and appearance, these lesions began as erythematous spots from which were gradually developed papules, at first

of small size, of pale red color and covered with smooth epidermis. Simple increase in the size of these lesions had transformed many of them into tubercles the size of a filbert, and several of them into veritable tumors. Wherever large numbers of such papules and tubercles came into contact with one another, they coalesced, forming patches of greater or less extent,

This plate is merely intended to show in a general way, the distribution of the eruption on the back.

irregular outline, with nodulated and fissured surface, and of a darker, more violaceous color than the primary and isolated nodules. For the most part these patches of conjoined lesions were covered with epidermis and only here and there were they excoriated and oozing. In none of the cutaneous lesions was there any retrograde change represented by the formation of pus or by deeply destructive ulceration, although the softness of some of the tumors suggested a fluid or semi-fluid contents, and one of them having been incised, discharged a dark red, almost black, grumous fluid. The large and protuberant tumors were luxuriant growths, from the surface of which, in some instances, the epidermis had been cast off, exposing to view the pathological tissue of which they were composed, and from some of these excoriated tumors there had been occasional hemorrhage of moderate amount. They resembled very much in appearance, although they greatly exceeded in size, the moist tumors

gous, oozing tubercles, which are sometimes met with in connection with parasitic sycois. When exposed to the air the thin, slightly bloody fluid exuded from their surface, dried to a thin crust, which was easily removed by friction or moisture. Decomposition of this fluid caused the patient to oftentimes emit a strong and peculiar odor, which resembled the united smells of sour cabbage and Parmesan cheese, being exceedingly offensive.

Within two years there had been apparent to the patient painless enlargement of the lymphatic glands in the groins and axillæ. The inguinal glands of both sides were much enlarged, having attained the size of large almonds, while along the outer edges of the pectorales muscles and behind the ears over the mastoid processes, lymphatic glands were to be felt as large as good sized peas. This enlargement of the lymphatic glands was of indolent and painless nature and they were unattached to the surrounding tissues, forming subcutaneous tumors over which the skin was freely movable.

The patient suffered no pain, and the cutaneous lesions were not sensitive to pressure but were, however, attended with severe and widely spread itching, causing him to scratch vigorously. Secondary lesions due to energetic use of the finger nails being manifest in several parts of the body. The patient was anæmic, the skin and mucous membranes being pale and the skin in general dry and rough. He complained of an unwonted feeling of weakness and easy loss of breath from slight exertion, together with violent beatings and palpitation of the heart, and the most trivial occurrence was oftentimes sufficient to throw him into a state of nervous excitement. There had been a loss of thirty pounds from the normal weight of one hundred and eighty pounds, but there was no emaciation, the patient's appetite was good, and there was fairly good performance of the digestive and excretory functions of the body. There were nowhere any cicatrices or atrophic spots on the skin, no cutaneous anæsthesia, no deafness nor failure of vision, and there had been no hæmorrhages from any of the mucous membranes, and no cough nor hæmoptysis. The result of the physical examination was as follows:

The ophthalmoscope detected nothing abnormal. The heart presented a systolic murmur heard over its base which was probably caused by anæmia, and there was sometimes irregular and rapid action of the organ, very likely due to the same cause.

The lungs were normal and the liver and spleen were not enlarged. The urine was found to be normal. Examination of the blood by Dr. Gannett showed the number of red globules in a cubic millimeter to be 3,722,000, and the number of white corpuscles 23,333, that is, moderate anæmia together with increase in the number of white corpuscles, giving a ratio of one white corpuscle to one hundred and fifty-five red, the normal ratio being about one white to five hundred red.

August 6th. The patient entered the hospital on the surgical side in the service of Dr. G. W. Gay, who kindly turned the case over to me. He was placed in one of the hospital tents, given the tincture of the chloride of iron, extra diet and received subcutaneously once a day, four minims of Fowler's solution of arsenic. Under these conditions he gained fourteen pounds in weight and rapidly improved as to his general condition, although no noteworthy change took place in the

state of the skin. The liberal use of an ointment containing one per cent. of carbolic acid gave him the most relief from the intolerable itching with which he was afflicted, more especially during the night. He left the hospital August 18th, but remained under observation until November.

August 30. Since leaving the hospital many of the erythematous spots which were upon the abdomen, thighs and arms had developed into papules.

September 5. Much of the diffuse erythematous redness about the chest had entirely disappeared, the restored whiteness of the skin contrasting in a striking manner with the red and violaceous color of the numerous papules and tubercles which were scattered about.

September 18. There was some improvement in the general condition, but no marked change on the part of the skin.

November 3. The patient complained of increasing weakness and shortness of breath upon exertion, which constrained him to remain quiet. A most striking change had taken place in several of the cutaneous lesions. The large tumor on the cheek near the corner of the mouth had entirely disappeared and its original site was covered with epidermis, while the largest tumor of all, that upon the right thigh, was also covered with epidermis and had diminished in size by nearly one-third. There was excessive desquamation all over the body and the inner surface of the thighs had assumed an eczematous condition, oozing in places and covered with yellow, honey-like crusts. There was also remarkable alteration in the appearance of the face which within a week had become extensively infiltrated, the skin being of a dull copper color and the countenance one of swollen rigidity, with effacement of the lines of expression.

This was the last time I saw the patient, as he afterwards disappeared, probably on account of the fatal and hopeless prognosis which he received in reply to a request for information as to his prospects. I afterward heard indirectly that he died in March of the present year, that is, about three years and eight months after the beginning of the malady. Before death he had been affected with gradually increasing exhaustion and diarrhœa. Two of the smaller nodules were excised while he was in the City Hospital and given to Dr. W. W. Gannett, pathologist to the hospital for examination, and the following is his report of their histological structure:

"Report on two nodules sent for examination by Dr. G. H. Tilden, August 13, 1884.

"Both nodules were hardened in Müller's fluid and later in strong alcohol. After the hardening process had been completed, the larger nodule measured 14 mm. in diameter, and was elevated 5 mm. above the level of the surrounding skin; the smaller nodule had a transverse diameter of 10 mm. and an elevation of 5 mm. The epidermis was intact upon them.

"A series of vertical sections was made with the microtome and then examined, stained and unstained, in various media. Sections were also brushed.

"Sections of the smaller nodule showed the following appearances:—

"All the layers of the epidermis, from the horny layer to the rete, were intact and showed no variation from the normal.

"The superficial parts of the corium, including the papillæ, showed the presence of masses of small round

cells arranged in groups of varying size and form, some being nearly circular, others irregular, others branching. In the centre of many of them a blood-vessel was to be made out. After brushing, these masses were found to be made up of a very delicate connective-tissue stroma, in the form of a fine mesh-work of connective-tissue fibres enclosing spaces. Each of these spaces enclosed one or two small round cells, having a large distinct nucleus with very little protoplasm about it.

"These cells correspond, morphologically, to lymph-corpuscles; their arrangement in the mesh described, makes this a cytogenous or lymphoid tissue.

"Where the above described patches were small and isolated the interlying connective-tissue of the corium showed nothing unusual. Where they were larger and in closer proximity, the intervening tissue of the corium was found to be converted into bundles of well-marked spindle-cells lying parallel to one another.

"In the deeper layers of the corium nothing remarkable was observed beyond a slight degree of round-cell infiltration of the adventitia of some of the blood-vessels. In the sub-cutaneous connective-tissue no appearances varying from the normal were discovered.

"Sections of the larger nodule showed appearances varying from those in the smaller nodule as follows:—

"The epidermis was intact.

"The papillae on the peripheral parts of the nodule were distinct; those in the central part, however, were very small; the rete Malpighi presenting a wavy line. This change was undoubtedly due to the pressure of the growing tissue beneath.

"The upper half of the corium was at least three times the usual thickness and was wholly occupied by a cytogenous tissue like that described in connection with the smaller tumor.

"This large area of lymphoid tissue was subdivided into smaller ones by narrow bundles of parallel-lying spindle-cells, which by anastomosis formed a coarse reticulum, having much the same relation to the lymphoid tissue that the reticulum of a lymph-gland has to its follicles.

"In parts of the lymphoid tissue were to be seen numerous red blood-corpuscles which from their arrangement were evidently contained in vessels, that is, in capillaries.

"The lower half of the corium, that portion bordering on the subcutaneous connective-tissue, showed many patches of lymphoid tissue, large and small, and of the greatest variety of form. Where this tissue was not present in patches one could make out round-cell infiltration in the spaces between the larger connective-tissue bundles and elastic fibres.

"In the subcutaneous fat-tissue the adventitia of the blood-vessels showed here and there round cell infiltration.

"The process in the larger nodule is evidently the same in character as in the smaller one, only more advanced. One has to do in both nodules with the development of a true lymphoid tissue in the corium; that is, a lymphoma.

"In neither of the nodules was any evidence of a nerotic or degenerative change discovered.

"Several months after the histological examination of the above specimens had been made, Kindschisch and Auspitz announced their discovery, in lymphomata like the above, of micrococci, which they claim are the specific micro-organisms of this affection.

"Although the nodules now described had been hardened in Müller's fluid and alcohol and were consequently much less adapted than fresh specimens or those hardened in absolute alcohol for demonstrating micro-organisms, yet the attempt was made to find them.

"Thin microtome sections were stained in Ehrlich's gentian-violet solution, then treated by Gram's method and examined in benzol balsam with an Abbe illuminating apparatus and a Zeiss 1-12 oil-immersion, but with a negative result.

"Sections were kept in alcohol for two months, then stained with an aqueous solution of methyl-blue, partially decolorized in alcohol and examined as before, but with a like negative result.

"Of course no special weight is to be attached to negative evidence in specimens hardened as the above were."

W. W. GANNETT, M.D.

Portion of brushed section showing the fine network of connective tissue present in the tumors, and the character of the cells of which the latter were composed. Drawn with the help of a camera lucida, Hartnack ocular iii, objective vii.

The first description of this disease by Alibert, was published more than fifty years ago, and since that time a sufficient number of cases have been placed on record to furnish us with a good picture of its clinical aspects. There is no instance of the malady having occurred in more than one member of the same family, and as a rule, the sufferers therefrom have been healthy individuals, free from venereal disease and of good family history, so that the elements of heredity, contagion, and syphilis may be eliminated from consideration.

In addition to the case reported in this paper, I have been able to find accounts more or less complete, of twenty-nine instances of this malady. The deaths of sixteen of these cases have been recorded, and the results of eleven autopsies have been published. One case of recovery is mentioned by Bazin as having taken place after an attack of migrating erysipelas, the patient remaining well for several years afterward, and the other cases were lost sight of, many of them in a condition which gave no hope of recovery.

Of these thirty instances of this disease, twenty-three occurred in males and seven in females, a remarkable disproportion in the matter of sex. The malady shows a tendency to develop in late adult life, more than one-half of the whole number of patients being forty years of age or over, at the time of the appearance of the disease. Of the remaining cases, one-half occurred in individuals of over thirty years of age, so that in only about one-quarter of all the cases, has the affection developed before the thirtieth year. The most advanced

age at which the disease has been known to occur is sixty-eight years, which was the age of Demange's patient; and there is no instance of its having developed before the twentieth year, if we exclude the case of an infant, reported by Landouzy to the Soc. de Biologie, which case has not been included in the above collection on account of its doubtful and exceptional character. The duration of the disease is usually from two to four years, with the extremes of two, four and five months in the cases reported by Galliard, Naether, and Debove, respectively; and of eight years, in one of Hardy's cases, mentioned by Kobner, and twelve years, in a case of Bazin's, reported by Guerard and Lorda. In a remarkable instance of this malady published by Port, there had been for thirty years, beginning with the fifth year of life, an almost continual manifestation of the various kinds of inflammatory, cutaneous lesions, and it was not until his thirty-fifth year, about six months before his death, that the characteristic fungous excrescences of mycosis fungoide began to show themselves.

The disease usually begins with the appearance on any and all parts of the body, of cutaneous lesions, which present no special characteristic by which they may be distinguished from changes which are met with in other and common affections of the skin. They may either be erythematous and urticarial in nature; may resemble eczema in being vesicular, moist, and covered with crusts, or may simulate psoriasis and lichen, by reason of their dry, infiltrated, and scaly character. At first, of a more localized and temporary nature, these lesions in the course of time, become more numerous and more tenacious of place, attended with greater thickening of the skin, and accompanied by pruritus of extreme severity, which is the only subjective symptom of which the patients complain. There are, however, exceptions to the above general rule, and the affection may begin with the immediate appearance of the tumors which are peculiar to it. Such was the case in the instances of this affection published by Demange, Galliard and Debove, which seem to have been of more acute development and shorter duration than usual. In two of these three cases, the tumors appeared first upon the breast, in the other upon the head; and in two of them there took place very early in the malady, extensive infiltration of the skin of the face, giving to the countenance the so-called leonine expression, seen in leprosy and scleroderma. After a longer or shorter period of time, during which the patients suffer from these apparently inflammatory changes in the skin and the attendant pruritus, and during which time there not infrequently occurs temporary cessation of symptoms, there appear the strange growths which are peculiar to mycosis fungoide, which foreshadow its fatal termination, and before the arrival of which, a diagnosis is impossible.

These tumors may arise either from preëxisting pathological patches in the skin, or they may develop in cutaneous regions which have hitherto been unaffected by disease. They consist in well-defined, rounded elevations of the skin, at first moderately firm and elastic in consistence, covered with smooth epidermis of a pale red color, and their attachment to the skin by a pedicle or narrow neck is very exceptional. They remain confined to the skin and are always movable with it, even in the most advanced stage of their development.

After they have attained a certain size, which, as in the present case, may be considerable, they remain un-

changed for a long period of time; but there takes place in some of them, sooner or later, a change which is one of the most notable features of the disease, namely, their disappearance by absorption, which may coincide with the appearance and growth of similar tumors in other parts of the body. When these growths have reached a large size, the epidermis may be cast off, as in several tumors of the present case, and superficial erosion occur; this process, however, not being inconsistent with the integrity of the tumors affected by it, which retain their size and shape, constituting the moist, fungous excrescences peculiar to mycosis fungoide. This form characterized by superficial loss of substance, is the more common variety of retrograde change, but there may also occur rapid and extensive destruction of these tumors, in which case they soften and open externally, thus forming large, suppurating, cutaneous ulcers.

In most of the cases, there has been painless enlargement of many of the lymphatic glands to a greater or less extent, and like the cutaneous tumors, this lymphatic enlargement may disappear by absorption. As a rule, the general condition of the patient is unaffected until after the appearance of the tumors; but eventually they become anæmic and debilitated, toward the end appear fever and diarrhœa, which together with increasing exhaustion, and in some cases, the formation of extensive and suppurating ulcers of the skin, close the scene, death generally taking place from marasmus.

Such is the clinical course of a malady, the pathological nature of which has given, and still offers sufficient opportunity for speculation, and the information furnished by the microscopic and post-mortem examinations remains to be considered. The results of microscopic examination of these tumors agree in showing the epidermal layers of the skin to be in a normal condition, but sometimes thinner than usual; the papillæ flattened and broadened, but well defined in most cases; and an infiltration of the connective tissue of the corium with round, granular, nucleated cells, resembling leucocytes in appearance. These cells may be disposed in groups and gathered around the blood-vessels, an arrangement which is more apparent in sections taken from tumors before they have reached an advanced stage of development, in which latter event, the cellular infiltration may extend as deep as the subcutaneous fat-tissue, in some cases replacing entirely the normal structure of the corium. Blood-vessels, hair follicles, and cutaneous glands may sometimes be seen imbedded in this collection of cells, and their sheaths infiltrated with similar elements. Ranvier was the first to detect and call explicit attention to the existence in these tumors of delicate, connective-tissue fibres, anastomosing so as to enclose spaces nearly circular in form, in which lie the lymphoid cells, a structure such as was found by Dr. Gammett in the specimens from the present case, and which is considered to be characteristic of cytogenous tissue. The existence of this meshwork has been remarked by all of the French observers, and the fact that careful brushing of thin sections is necessary to determine its presence, may account for its having been overlooked by several investigators.

The most noteworthy fact to be derived from the autopsies is the negative one of the absence in any of the internal organs of metastatic growths similar to those in the skin. The nearest approach to such a condition of things was found in the autopsies reported

by Dühring and Galliard, in each of which was detected in the walls of the bladder, beneath the mucons membrane, round-cell infiltration resembling that in the skin, while in addition to this Galliard describes the presence in the heart, lungs, liver and testicles, of small circumscribed collections of leucocytes, "apoplexies lymphatiques," the character of which was determined by the microscope. In one case only, that of Debove, were the tonsils the seat of ulceration, following an enlargement of these glands which had been apparent during life. In the great majority of cases there was found increase in size of the lymphatic glands in various parts of the body, a change which the microscope has shown to be of the nature of hyperplastic enlargement. In two instances some of these enlarged glands were found to contain small collections of pus and there was also purulent infiltration of the surrounding connective tissue. In only two cases was the spleen notably enlarged, in three cases it was slightly increased in size, and in the rest, of normal dimensions. The details with regard to changes in the other internal organs are slight and possess no special significance.

The theories with regard to the pathological nature of mycosis fungoïde are three in number:

- I. That it is generalized sarcoma of the skin.
- II. That the new formation of lymphoid tissue in the skin renders the disease a variety of pseudo-leukæmia.
- III. That the new growths are so-called infective granulomata of the skin, that is, young connective-tissue tumors associated with the presence of special microorganisms.

As to the first hypothesis, the weight of evidence is against the disease being sarcomatous in nature. The clinical course of the disease and the appearance of its cutaneous lesions are unlike the same factors in the cases of multiple sarcoma of the skin as described by Köhner and Kaposi. The curiously unstable character of the pathological products of mycosis fungoïde, their comparatively rapid appearance and subsequent disappearance by absorption and by necrosis, are conditions not usually observed in connection with sarcomata which, generally speaking, are permanent and stable growths. The microscopic structure of the tumors of mycosis fungoïde is that of a lymphoid tissue rather than that of typical sarcoma, while the absence of so-called metastatic growths is the absence of what is one of the most marked tendencies of some varieties of sarcoma.

With regard to the affection being leukæmic or pseudo-leukæmic in nature, this theory is based solely upon the microscopic structure of the tumors of mycosis, more particularly upon the presence therein of a finely-meshed cell holding reticulum, such as is found in lymphatic glands and in cytogenous tissue, generally so called. So little is known as to the true nature of leukæmia and pseudo-leukæmia that speculation as to their possible relationship with mycosis fungoïde is rather barren of definite conclusions, but it may be said that something more than the knowledge of the minute structure of pathological products at any one stage of their development, is necessary to render evident their pathogenesis. In none of the very few cases of mycosis fungoïde, in which the blood has been examined, has there been found sufficient increase in the number of the white corpuscles to constitute typical leukæmia, while in only two of the autopsies has there

been found notable enlargement of the spleen, an enlargement which together with that of the lymphatic glands is an essential feature in pseudo-leukæmia.

A remarkable case, which demands attention in this connection, has recently been published by Kaposi, as a hitherto unrecognized form of disease, under the name "Lympho-dermia perniciosa." Up to a certain point the features of this case bear some likeness to those of mycosis fungoïde. There was the same preliminary manifestation of chronic inflammatory changes in the skin attended with pruritus and lasting a year, followed by the development of numerous cutaneous tumors and enlargement of the lymphatic glands. The tumors in this instance, however, did not disappear by absorption or form the typical moist fungous excrescences of mycosis fungoïde, but simply softened, opened and formed suppurating ulcers.

In addition to the above phenomena, these ultimately developed undoubted evidence of leukæmia, which was confirmed by the autopsy.

There was marked increase in the number of the white blood corpuscles, the spleen was found after death to be four times its normal size, and nodules were detected in the lungs, pleura and medullary cavities of the bones, which together with the cutaneous lesions were shown by the microscope to be composed of cytogenous tissue. The only other instance in which the development of lymphoid tumors in the skin accompanied the course of typical leukæmia was in a case reported by Biesiedeckí, in which case there is no mention of retrograde change in any of the tumors, the appearance of which was preceded by the development of the general leukæmic condition, and not as in Kaposi's case, followed by it.

Within the year Rindfleisch and Auspitz have each described the existence in the pathological products of mycosis fungoïde, of microorganisms, the presence of which is considered characteristic of the so-called infective granulomata, represented by tubercle, lupus, leprosy, rhinoscleroma, and most recently of all, syphilis. Rindfleisch describes them as streptococci, which he expressly states are to be seen only within the blood vessels, the plugging of whose calibre by these microorganisms is sufficient in his opinion to give rise to the cellular infiltration of the surrounding tissues, while their removal by the force of the blood current, is supposed to account for the peculiar disappearance by absorption of the lesions of mycosis fungoïde. Auspitz, on the other hand, using the same methods of staining, states that there exist large numbers of micrococci in the pathological tissue outside of the blood vessels. It is impossible to avoid the suspicion that the presence of these micrococci, mentioned by Auspitz, is simply accidental. There is nothing to be said concerning the latest theory, except to remark the discrepancy between these observations, and bearing in mind the prevalent rage for the detection of microorganisms, to await further developments. It is possible that these observations point in the wrong direction; it is not impossible that therein may eventually be found the answer to the naive question of Demange with regard to mycosis fungoïde. "*N'y a-t-il donc pas là quelque chose de spécial qui nous échappe encore ?*"

### THE RAPID FATALITY OF TUBERCULOSIS WHEN INVOLVING THE PHARYNX.

BY THOMAS AMORY DE BLOIS, M.D.

It would be a waste of words to speak of the usually fatal termination of Tuberculosis in general. No case of undoubted Laryngeal Tuberculosis has ever been known to recover, but when the tubercle implants itself in the mouth or pharynx, the fatal termination is as noticeable from the rapidity with which it supervenes as for its inevitability.

In proof of this I would bring to your notice the following cases:

CASE I. William M., a messenger, employed at the City Hospital, about nineteen years of age, was

frequently treated by me during the spring of 1884, at the City Hospital Out-Patient Department for catarrh of the pharynx and larynx. There did not seem to be the usual small amount of improvement which follows the treatment of these cases. There was a good deal of cough, but although I never examined the lungs, I understood that they were supposed to be somewhat affected. He soon after left the hospital, as I believed, to seek improved health in the West. He went, however, to New Hampshire, and after his return came to the Throat Clinic at the City Hospital, where I saw him the last of February.

On examination I found three deep ulcerations of the posterior wall of the pharynx and the bottom and ragged edges of these were studded with small yellowish spots which were apparently tubercle in different stages, some broken down and some not. The larynx, although greatly swollen, did not show any ulcerations or tuberculous nodules.

From the records of Dr. F. W. Draper's ward, in which this patient was, I quote the following notes of the case:

On examination 19th. William M., aged twenty, single, born in Boston. Father, mother and two sisters died of consumption. Does not drink, except a little beer. No venereal history; always well up to a year ago, then began to cough and have pain in the right lung. Eight years ago raised a tablespoonful of blood, bright red in color, not clotted, and it came up without coughing. Patient has had night sweats for about a year, cough has grown worse for about three months, has lost twenty-eight pounds in the past year, complains of sore throat and catarrh. Temperature 101, pulse 90, respiration 28. Urine normal. Lungs showed physical signs of incipient phthisis in both upper thirds, more marked in left than in right. Patient was put on oil malt, cough mixture, atrophy, etc.

February 28th. Examination of throat by Dr. De Blois shows it to be Pharyngeal Tuberculosis. Epiglottis and aryepiglottic folds swollen, but very little ulceration.

March 15th. Application of four per cent. solution of cocaine gives temporary relief.

March 20th. Examination by Dr. J. Orne Greene showed chronic purulent inflammation of right tympanum, and was syringed out with one to eighty carbolic acid solution.

March 29th. Slow retrogression, growing weaker.

April 7th. Amphoric respiration and tympanic resonance in cardiac area, failing fast. April 7th. Discharged, dead, no autopsy.

As to the local treatment of this case, which I saw from day to day whenever the patient was able to come to the Out-Patient Department, it consisted mainly in the careful cleansing of the pharyngeal ulcerations, and whenever possible, the insullation of iodoform, under which treatment they somewhat diminished in size, but in this case, as in a case of laryngeal tuberculosis which I treated, iodoform appeared to distress the patient.

I cannot speak too highly of the action of a ten per cent. solution of cocaine which I used; it so relieved the dysphagia that deglutition became possible, and the patient came to have his pharynx painted immediately before his dinner so as to be sure of having one good meal during the day.

Shortly before his death, which it will be observed occurred within two months after the appearance of

the pharyngeal ulcerations, there were some small ulcerations on and around the larynx.

CASE II. Mrs. Rosa B., aged twenty-nine, consulted me at the Boston Dispensary on July 8th of this year. She said that she had been suffering for some time past with a sore throat. Upon examination I found the entire soft palate studded with small canary-colored points about as large as the head of a good-sized pin, and many of them larger. Some had pushed their way to the surface of the mucous membrane, in fact protruded above it, so that when the patient's head was slightly moved, it was easily seen that they were projections. As they approached the lower border of the velum, they were in most cases broken down, and discharged a thin, watery secretion. The uvula presented a surface covered with ulceration.

These masses of tubercle covered the anterior pillars of the fauces and the edges of the tongue at their junction with it. The walls of the pharynx seemed to be free from the disease.

On examining the larynx, the epiglottis showed three or four spots at its upper border and the aryepiglottic folds contained two or three, but these were in a far less advanced condition than those on the velum.

This examination was repeated by Drs. Leland, V. Bowditch, Bullard and others. Dr. Bowditch made an examination of the chest for me and found dullness and crackles in the left clavicular region.

The patient was at this time far advanced in pregnancy and I ventured the assertion, to her friends, that she would remain about the same until after parturition, and would not long survive that event.

Deglutition was not very painful, and the patient was moderately well nourished. She stated that the sore mouth had only been of three weeks' standing. Her family history, as regarded phthisis was very bad. There was no suspicion of syphilis. She further stated that she had been examined at the Carney Hospital, and Dr. Bullard, who saw her, has kindly furnished me the following notes.

June 22d, 1885, Rosa B. Phthisis, Follicular Pharyngitis and Uvulitis. Has sore throat; has had a cough for three months, now slight; hæmoptysis ten days ago; pain in left side; catarrh of left eustachian tube; dullness with moist râles and bronchophony in right front; bronchial respiration with dullness left apex behind; bowels regular; prescribed Hypophosphites, etc.

The subsequent history of this case was not a long one. As I had anticipated, she did pretty well until the birth of her child, about five weeks after my first examination, then the disease advanced with great rapidity, the ulceration of the tubercles rapidly increased until the mouth was filled with this suppurating mass. Nourishing the patient became next to impossible, and she died from exhaustion on September 7th, three weeks after parturition, and less than three months after the first trouble in the mouth was observed.

The treatment was about the same as in the first case, oil and opium, and iodoform and cocaine locally.

Reviewing two other cases reported by me in a paper read before the American Laryngological Association, May, 1884, and making a brief synopsis of their histories.<sup>1</sup>

The first was that of a man of thirty, who noticed

a soreness of the palate in December, 1882, and died from exhaustion at the Carney Hospital on the 8th of March following, a little over four months.

The second was that of a young woman of twenty-four, who, having been under treatment for Laryngeal Tuberculosis, developed about the first of September, 1883, a tuberculous ulceration of the right tonsil. She was received at the City Hospital and there died from exhaustion on the 22d of October following, or within two months after the pharyngeal deposit.

There have been from other sources, generally European, about twenty-five cases reported, and these almost always with rapidly fatal terminations.

Whatever the results may have been from the treatment of tuberculosis of the lungs there has been but one in the variety of which I speak, death has inevitably ensued, and in the four cases which have come under my care, have, by but little exceeded three months in time. Indeed, so invariably has this been, that should a case be reported terminating in recovery, it would be sufficient ground for distrusting the diagnosis.

That this rapid fatality can be accounted for on the score of the interference with nutrition is hardly true, for severe laryngeal ulcerations certainly make deglutition much more difficult, and yet the duration of life in such cases, I have found somewhat longer.

There seems to be an amount of distress inherent to the pharyngeal ulceration which we find under no other circumstances. In both of the first cases mentioned, although the tubercles had invaded the larynx, yet the voice was not interfered with beyond a slight hoarseness, and it was not from the larynx that the pain in swallowing proceeded.

## CASES OF GLYCOSURIA.

BY J. B. AYER, M.D.

I WILL venture to define glycosuria as a *symptomatic* form of saccharine diabetes where polyuria is absent, or, if present, soon disappears, which yields to treatment though subject to relapse, and does not affect unfavorably the general health.

In importance it rests between the *temporary* form of diabetes (connected with weaning, with convalescence from acute disease, etc.) and *true* diabetes with polyuria, excessive thirst and emaciation.

A recent writer upon the subject of diabetes, Satterthwaite (*Medical Record*, April 11, 1885,) states that cases of this kind are comparatively uncommon, but *occasionally* occur among old and obese men, though sometimes in the middle period of life. I believe, however, that glycosuria is by no means rare among the middle-aged and old, and that it often exists for a long time unrecognized.

Whether the different forms of diabetes should be grouped together pathologically will be discussed later.

I will give a brief account of four cases of glycosuria seen during the past year.

CASE I. October 2, 1884, I was attending a lady sixty-five years of age for a mild attack of bronchitis. She was exceedingly nervous, at times her nervous system was with great difficulty kept under control. She was well nourished with a tendency to corpulence. When she mentioned that she was troubled with pudendal irritation I examined the urine and found a large amount of sugar, although the amount of urine did not

<sup>1</sup> New York Medical Journal, November 8th, 1884.

exceed the normal. She told me that she had always been very fond of sugar, keeping it in her room and consuming three pounds each week, in addition to the ordinary amount required in cooking!

From November 1882, to April 1883, she was under the care of Sir Andrew Clark of London, for "nervousness and acid urine." He gave her a written statement (twenty months before I saw her) that an excess of uric acid was present in the urine, but that he had never found sugar.

Dr. E. G. Cutler early examined a specimen of the urine with the following result: acid; sp. gr. 1041; urea, chlorides, sulphates, and earthy phosphates, normal; albumen, a faint trace; sugar, twenty-two grains to the ounce. By microscope, torula spores, flat epithelium, a few leucocytes, and a couple of narrow hyaline casts. The albumen and casts evidently had no connection with disease of the kidneys.

A week later she had recovered from the bronchitic attack. The urine was normal in amount, acid, sp. gr. 1035, contained no albumen but seven per cent. of sugar.

When I found the large percentage of sugar I was alarmed in regard to her condition, especially as she was unwilling to restrict herself in the matter of diet; insisting upon still taking what most persons would consider a satisfactory amount of starch and sugar. Moreover she kept the house and could not be induced to go out of doors.

I was much surprised, as well as gratified to find that, in spite of neglecting my advice, she enjoyed good health during the winter.

April 29, 1885, I found that she had a poor appetite and was somewhat debilitated, and also noticed a slight roughness of the finger-ends. Gave tonic treatment. June 25, 1885, patient again needed a tonic mixture, although she was no more debilitated than could be expected from her voluntary confinement to the house.

The urine at this time contained seven and one-half per cent. of sugar. Less than three pints in twenty-four hours was voided.

August 29, 1885, she reported that she had taken a daily walk during the preceding two months, and had been out of town for a few days.

Although very careful in all other particulars, and anxious regarding her health, she did not wish to speak of the diabetic condition, although she admitted that pudendal irritation was present.

As she has improved in every respect, (especially in regard to the nervous symptoms,) and probably has not enjoyed such good health for several years, we have tacitly ignored the subject of glycosuria, although I have no doubt that the urine still contains a large percentage of sugar.

CASE II. Gentleman, forty-eight years of age, has been under my care four years for sequelae of syphilis contracted in 1875. He is corpulent; height five feet seven inches; chest measurement, inspiration, forty-two inches; expiration, thirty-nine inches; waist, forty-two inches; weight fluctuation during past four years between one hundred and ninety-seven and one hundred and eighty-five, present weight one hundred and eighty-seven.

From July to November, 1880, I treated him for squamous patches upon the hands; in October 1881, for blotches on the hands; during the summer of 1883 for a slight induration of lower lip; in November and December, 1881, for an eczematous patch on the wrist, and superficial ulceration of lips.

He bore iodide of potash well, but could take only small doses of mercury. The mercury, however, was more effective.

Examinations of urine in 1880 showed specific gravity fluctuating between 1015 and 1023: it was not thought necessary to examine for sugar.

November 30, 1881, he casually mentioned that he was slightly troubled with irritation at the end of the urethra, and said that for some weeks he had been more thirsty than usual. The amount of urine was found to be normal, but containing 2.08 per cent. of sugar. He was asked to partly abstain from starch and sugar.

December 1. Amount of urine three pints; sugar 5.35 per cent.

December 6. Urine two pints. Sp. gr. 1038. 6.9 per cent. sugar. He was placed upon full diabetic diet and ordered Clemen's solution of arsenite of bromine, three minims, largely diluted, after each meal.

December 19. No sugar.

December 26. Is allowed one slice of crisp toast, one lump of sugar, and one potato daily. Urine sp. gr. 1027, contains a trace of sugar.

January 2, 1885. No sugar.

January 4, 1885. 1019, minute trace of sugar.

January 11, 1885. 1021, no sugar.

January 22, 1885. 1027, no sugar.

January 25, 1885. 1023, no sugar.

February 4, 1885. 1029, trace of sugar.

February 22, 1885. Passes two pints in twenty-four hours, no sugar.

The urine was examined after eating. He said that he noticed a good effect from the rigid diet. Four years ago, (shortly before he came under my care,) he had been treated for uric acid diathesis. I had never found an excess of uric acid in his urine, but some myalgic symptoms and (as he expressed it) a "logy feeling of the bowels," were probably connected with the uric acid tendency.

Patient attended to his business regularly during the spring and summer, returning gradually to his usual diet, which did not include an excess of hydrocarbons.

I did not see him professionally during this time, but called upon him September 12, and asked him for a specimen of his urine. "I will send it if you wish," he replied, "but I do not believe it is necessary to examine it as I have not felt so well for many years as I do now."

The specimen contained two and one-half per cent. of sugar, and a decided layer of albumen, but no casts. Amount less than normal. He was again placed upon full diabetic diet and Clemen's solution.

September 26. Urine less than three pints daily. Acid 1022; no sugar. Decided layer of albumen; urea about normal; nothing abnormal on microscopic examination.

October 1. Urine three pints; acid 1018; no sugar. Less albumen, although a decided trace. Microscopical examination negative.

He was ordered to continue diabetic diet, but to substitute for Clemen's solution small doses of biniodide of mercury with iodide of potash for psoriatic patches upon the wrist.

CASE III. Gentleman, sixty-seven years of age. Was under my care two months in the early part of the present year for cystitis and prostatitis accompanied by the usual nervous excitement.

Although he took a large amount of fluids at first, I never found an excess of urine. At times less than three pints of urine was voided in twenty-four hours.

When I first began to examine the urine the specific gravity of specimens passed after meals fluctuated between 1027 and 1030 and contained two per cent. of sugar and a large sediment of pus.

Under a restrictive diet (containing however, a large amount of milk,) and Clemen's solution, the sp. gravity fluctuated between 1019 and 1025, and the percentage of sugar was lowered to 1.68 and less.

Taking into consideration the nervous state, which accompanied the disease of the urinary organs, I was surprised to find the glycosuria kept well under control, and could not believe that it was a symptom of importance in the case.

CASE IV. Gentleman, over fifty years, has suffered from neuralgia and myalgia, and has passed an excess of uric acid.

May 13, 1885, he told me that he had recently noticed a sticky deposit on his linen, and said that there was slight pruritus about the meatus urinarius. He had always been a great water-drinker, and was then drinking somewhat more than usual.

He had always taken sugar to excess. The urine, passed two hours before dinner of that day, had sp. gr. 1035 and contained 6.9 per cent. of sugar. Urine passed one hour after the completion of dinner was of sp. gr. 1031, and contained five per cent. of sugar.

For a few days he voided a little more than the normal amount of urine, but soon the amount was reduced to three pints in twenty-four hours.

At first I allowed a limited amount of starch and sugar in his diet.

June 9. Urine had sp. gr. 1027; sugar two and six-tenths per cent.

July 3. 1022, no sugar.

July 16. 1028, about three per cent. of sugar.

July 22. 1027, trace of sugar.

He was now placed on Flint's dietary and milk, and given Clemen's solution, three minims three times daily.

August 5. Urine strongly acid; sp. gr. 1025; minute trace of sugar; the sediment contained uric acid crystals, appearing microscopically as flat chisel-ended plates, the edges of the crystals modified by the saccharine urine as described by Dr. W. M. Ord.

August 10. The urine was acid, sp. gr. 1027, and contained one per cent. sugar. Patient had been indulging in green corn.

August 14. It was acid; sp. gr. 1026, and contained a minute trace of sugar.

August 22. For the first time during the three months of treatment there has been noticed an increased amount of urine and a large amount of sugar.

On inquiring I found that it was due to a temporary nervous condition depending upon anxiety.

September 3. Normal amount of urine but a large percentage of sugar.

September 11. Urine acid; sp. gr. 1019; no sugar. Is feeling remarkably well.

September 19. Acid; 1026; no sugar; microscopically, a few oxalate of lime crystals; urea normal.

September 30. Sp. gr. 1026; no sugar.

The influence of the mind and nervous system upon the glycosuria was very marked. Patient had not for years suffered so little from neuralgic symptoms. The

loss of a few pounds of flesh has improved his general health. He is a very active business man, and has not been in better health for many years.

I am greatly indebted to T. Metcalf & Co., for the numerous quantitative analyses of sugar reported.

These four patients whose ages range between forty-eight and sixty-seven, are all in a position to give themselves the best of care, and none have ever taken alcohol to excess.

They are all stout; the waist measurement corresponding to chest inspiration more closely than to expiration.

In each case the discovery of sugar in the urine was a surprise to me, for the thirst and polyuria were absent or of short duration, and none of the debilitating symptoms which accompany diabetes mellitus were present; on the contrary the three cases I am following have, while losing a few pounds of superfluous flesh, gained strength in a marked degree and now enjoy better health than for many years past. The gentlemen are very active business men.

In all these cases the uric acid diathesis, and in three the functional disturbance of the nervous system preceding the discovery of sugar in the urine were strong proofs that the glycosuria was *symptomatic* in character.

Claude Bernard stated: "The glycosuria which is accidental, *symptomatic*, and transitory, does not constitute the special disease for which the name of saccharine diabetes ought to be reserved; it no more constitutes diabetes than albuminuria when symptomatic of the heart, or serious fevers, constitutes the special affection, Bright's disease."

Prout stated as long ago as 1810, that "A saccharine condition of the urine is much more common in dyspeptic and gouty individuals than is supposed. I have seen many cases of the kind in old people, and my experience is that glycosuria occurring in advanced age in gouty persons is not the terrible symptom which it is often held to be."

The direct dependence of glycosuria upon an uric acid diathesis has been recognized by several writers.

Dr. Dyce Duckworth in his paper (in St. Bartholomew's Reports for 1879) upon "Some irregular Manifestations of Gout," speaks of the importance of the relation undoubtedly existing between the gouty diathesis and glycosuria.

"I believe," he says, "that many cases of temporary glycosuria are due to gouty conditions. The fleeting presence of glucose in the urine of many elderly persons may be thus explained. It has long been recognized that such an affection, which in many cases is undeserving of the name of diabetes mellitus, for the simple reason that there is no diabetes in the strict sense of the term, is not really a grave one. The presence of glucose is found to alternate with that of uric acid. In the aged but little importance should be attached to the symptom—under forty years of age, however, glycosuria, even of gouty origin, is a most grave matter."

Charcot speaks of uric acid gravel or gout *alternating with diabetes*, and speaks of this form of diabetes as "in general relatively benignant, especially if the patient follow a suitable diet."

The nervous element was a still more important etiological factor in the three cases.

All writers agree in maintaining that prolonged nervous excitement, worry, mental strain, or mental shock are frequent causes of glycosuria.

Senator states (Ziemssen's Cyclopaedia) that "psychical impressions have proved the immediate occasion of the disease or have aggravated it after temporary improvement has taken place—as well those of *sudden occurrence* like fright, anxiety, or anger, as those of *longer duration* like grief, solicitude, and cares. Examples of this were known to T. Willis (1645) and in subsequent literature they are found constantly repeated in great number, especially in times of stirring or shocking events. For instance, the period of engrossing stock speculation in Berlin exerted an unmistakable influence upon the development or the aggravation of diabetes. Immoderate mental strain, too, is occasionally specified as the only ascertainable cause."

It has been shown by experiment that a diet containing starch or sugar in great excess may cause glycosuria.

In two of our cases the patients have always eaten an immoderate amount of sugar.

Case two brings up the question whether or not syphilis is a predisposing cause of glycosuria.

Blau (Schmidt's Jahrbücher, 1884), states that the connection between syphilis and diabetes has been but rarely observed, very few autopsies showing an etiological connection. He agrees with Scheinmann that "Diabetes can hardly be considered of syphilitic origin without brain lesions."

There have never been any symptoms of cerebral disturbance in our case.

We come now to the interesting question whether diabetes mellitus and glycosuria are alike from a pathological standpoint. Are they essentially the same disease, differing in degree only?

It is humiliating to answer that in spite of the time and study given to the subject during the past few years by eminent observers we must still admit our ignorance of the exact pathology of diabetes. We do not yet know that it is a *distinct disease* having definite lesions.

In 1848 Claude Bernard proved that puncture of the fourth ventricle of the brain produced hyperaemia of the liver and glycosuria. The connection between the brain and liver, as stated by Silver, is by way of sympathetic fibres in the medulla oblongata which descend in the spinal cord to the lower cervical or upper dorsal vertebra, thence to leave the cord to join the gangliated sympathetic and so ultimately to reach the liver.

Irritation of the brain in the neighborhood of the fourth ventricle cannot be the most frequent cause of glycosuria, for Dr. Windle who examined one hundred and eighty-four records of autopsies of diabetes where the brain was examined, reports that in ninety-one the brains were apparently normal. In twenty-three per cent, only were there lesions of the medulla oblongata, and no one change was seen in more than four cases. He found greater diversity in the lesions of the brain than in any other organ.

The same observer reports seventeen examinations of the sympathetics, in nine of which the ganglia were found abnormal. Five of the nine showed an increase of connective tissue and thickened cell-capsules, with diminution of cells and of medullated fibres in ganglia.

The sympathetic system is deservedly receiving the most attention in connection with the etiology of diabetes.

Dr. Hale White reported (*Lancet*, London, December 29, 1884), four cases of diabetes mellitus where

microscopic examination showed abnormal sympathetics usually of a chronic inflammatory character.

Dr. Windle also found that, in eighty-four of two hundred and twenty livers examined, microscopical examination failed to discover any change pathognomonic of diabetes. In only sixty-nine cases was congestion with or without enlargement, found.

In 115 cases out of a total of 271, the kidneys showed no pathological signs which could be connected with diabetes.

In the pancreas the changes were in the direction of atrophy, only sixty-five out of 139 being normal.

The *Lancet* draws the following conclusions from the debate upon the pathology of diabetes at the London Pathological Society in 1883:—

"Diabetes is not associated with definite structural lesions of any organ; it is due to disturbance of functions of the liver brought about apparently by a peculiar condition of the circulation in that organ; this condition, vaso-motor paralysis, can be induced experimentally in the living animal.

"The question was left open whether in diabetes this vaso-motor paralysis is caused *directly* by disease of the sympathetic or *indirectly* by the action of some chemical fault originating in the chylipoetic viscera or in the blood itself."

Albuminuria frequently occurs in connection with glycosuria. It was unexpectedly found in cases one and two. According to Senator it is not a form of Bright's disease, as nothing more than hypertrophic swelling and fatty infiltration of renal epithelium are found—changes on the border line between the physiological and pathological state.

Claude Bernard discovered that irritation of the fourth ventricle a little above the "sugar-point" caused albuminuria, and that a considerable amount of irritation in that neighborhood would cause both albuminuria and glycosuria—the former through sympathetic fibres passing from the spinal cord to the abdominal plexus and thence to the kidneys.

As to treatment. In spite of the case, which is evidently doing well without much regard to my advice, I do believe in full *dietic, hygienic, and medicinal* treatment for cases of glycosuria, and cannot agree with Ralfe, who has recently stated that the influence of diet upon glycosuria is not so marked as in diabetes mellitus.

In 1875 I saw Murchison prescribing sugar freely in a case of diabetes, but now most observers agree with Tyson "that the normal assimilating action of the liver stores up carbo-hydrates as glycogen and then gives them out as glucose or maltose to be oxidized; *this being deranged*, such foods become useless and *aggravate* the glycosuria."

The Dietary of Austin Flint, Jr., is an excellent one, especially such dishes as minced beef, turkey or chicken with poached eggs, scrambled eggs with chipped smoked beef, pickled salt cod-fish with eggs, and omelettes in great variety.

Milk, I would add to his diet-list, agreeing with Tyson that in the early stages of diabetes Lactine or Sugar of Milk is quite assimilable and does not in the slightest degree contribute to the production of glycosuria.

I cannot agree with Flint in believing that in two or three weeks patients lose their craving for prohibited articles of food, yet can testify that patients readily adapt themselves to the new diet and that in a surpris-

ingly short time it is no longer irksome. I think that he is wise in allowing a crust of half a French roll (or a thin slice of toasted bread,) occasionally in preference to gluten-bread, on the ground that then he knows the exact amount of starch given.

I would not give glycerine.

The hygienic treatment should be carefully carried out. Exercise in the open air, sponge bathing and friction (with Turkish towel), should be commended.

As for treatment by drugs a good tonic is indicated. Arsenic has been recommended for a long time, and I feel favorably disposed to Clemens's solution of arsenite of bromine, although from these cases it would be difficult to estimate its exact worth. I believe that is a *sedative tonic*. The preparation manufactured by T. Metcalf & Co., contains one per cent. of arsenious acid. The dose I have used was from two to four minims, largely diluted, after meals.

Tonics containing the phosphates are undoubtedly of great value in connection with a diabetic diet.

Constipation due to change of diet is easily regulated by Hunyadi water.

I would keep patients under full treatment at least a month after the disappearance of sugar from the urine, and then drop the medicine and *very gradually* add starch and sugar to the diet-list, testing the urine weekly.

## Reports of Societies.

### BOSTON SOCIETY FOR MEDICAL OBSERVATION.

H. L. BURRELL, M.D., SECRETARY.

October 5, 1885. Dr. F. GORDON MORRILL, in the chair.

Dr. T. A. DEBLOIS read a paper on

#### "THE RAPID FATALITY OF TUBERCULOSIS WHEN INVOLVING THE PHARYNX."

Dr. F. H. HOOPER spoke of the rarity of the disease. At the Throat Clinic at the Massachusetts General Hospital, during the past five years, not a single case had been observed.

On looking up the statistics, Dr. Hooper had found it stated that out of three to four hundred cases of tuberculosis which came to Guttmann's clinic, only one per cent. was affected by tuberculosis of the pharynx. Another observer met with only ten cases out of a total of sixteen thousand patients. Although twenty per cent. of all these were affected by disease of the air passages, and it was always in those patients in whom tuberculosis of the lungs and larynx was very far advanced that this complication was manifested.

Considering Dr. Strassmann's results in regard to tuberculosis of the tonsils, Dr. Hooper thought it singular that tuberculosis of other regions of the pharynx was so seldom encountered. Strassmann's investigations showed that in nearly every case of pulmonary phthisis small military tubercles and bacilli were found in the tonsils. It is rare for tuberculosis of the tonsils to lead to caseous degeneration or destruction of the organs, which may account for its being solidification seldom seen clinically as is the disease in other parts of the upper pharynx.

Dr. E. O. ORIS asked what the condition of the lungs was in the first case.

Dr. DEBLOIS replied that there was some modification but no cavity formation.

Dr. KNIGHT said that cases of tuberculosis of the pharynx were very rarely reported, and stated that he had never seen but one case. Dr. Cohen had for a long time doubted its existence until he had seen a case where there were no signs in the chest, the patient complaining only of soreness in swallowing food, and gradually the characteristic yellowish tubercular spots appeared.

He did not feel that one could be so sure about the universal fatality of the affection, for there existed somewhat the same doubt regarding the diagnosis as existed in diphtheria; where some observers reported many cases with a large percentage of mortality, and others reported as many cases with only a small percentage of mortality. The interference to deglutition undoubtedly was a prominent factor in causing a fatal termination.

Dr. Knight also spoke of the difference in fatality of cases of laryngeal tuberculosis. Where the posterior parts of the larynx were involved a fatal termination quickly followed. This rapid fatality occurs when there is a perichondritis.

Dr. Knight said that there were, however, many cases where there was a superficial ulceration and great congestion, which could be greatly relieved where there is trouble confined to and about the vocal chords life may continue a long time.

Dr. Knight suggested that these cases involving the pharynx would be appropriate for the bichloride treatment as they could be so easily reached.

Dr. J. B. AYER read a paper on some

#### "CASES OF GLYCOSURIA."

Dr. F. C. SHATTUCK expressed great interest in hearing the valuable paper which illustrated how important saccharine urine often is in those who have reached middle life and are of a full habit. The term glycosuria seems to be used by the reader in a somewhat different sense from that given to it by some, who include under this head transitory and intermittent conditions, under the term diabetes persistent conditions. The term is a most convenient one in practice, and this very convenience favors perhaps looseness of application. To the lay ear the word diabetes has a very ominous sound, the affection denoted by it being considered one of the most serious to which flesh is heir.

The relation of the mild to the severe cases is, as the reader suggests, almost equally obscure and interesting. If sugar in the urine is but a symptom common to several distinct conditions, is the pathology of the mild different from that of the severe case? It is difficult to see why the same or similar causes, but of different intensity and acting on different organisms, should not produce very widely differing effects. It may well be that a failure to diagnosticate diabetes before the patient presents the classic symptoms of polyuria and increased thirst and appetite with progressive emaciation, is quite analogous to overlooking phthisis until large cavities are formed. In other words, we know much more about diabetes in its maturity than about its formative or even its youthful periods.

The speaker then briefly alluded to several cases seen during the past year. A lady of fifty, spare and of nervous temperament, consulted him about a year

<sup>1</sup> See page 392.

<sup>2</sup> See page 393.

ago and asked that her urine be examined, as she had noticed a dryness of the lips of late, and her grandmother and mother had both died of diabetes. There was slight polyuria and the urine contained nine per cent. of sugar. Under strict diet the sugar disappeared entirely and the quantity came down to the normal. She now does well under a moderately restricted diet, and is in much better condition than a year ago. The second case was that of a very vigorous young man of twenty-four, seen several times in consultation. The sugar was looked for about a year ago, and for two years previous to that time he suffered from headache, dyspepsia, and neuralgic pains. During the past year the improvement has been decided and the patient does not seem likely to bear out the bad prognosis assigned to the periods of life under forty. The third case was one of genuine diabetes in a child of four years, brought to the Massachusetts Hospital for eczema of and about the vulva. Dr. White, on hearing that the child made a great deal of water and that the diapers became stiff when dry, caused the urine to be examined. Sugar was found in large amount, and the case was referred to the medical department. In so young a child belonging to a poor family the withholding of starch and sugar was, of course, impracticable, and the patient died of diabetic coma about a month after it first came under observation.

Dr. C. E. STEDMAN inquired if there were any cases of recovery recorded where there was sugar in the urine of patients under twenty years of age.

Dr. AYER said that cases were almost always fatal under forty years of age.

#### MEETING OF THE PHILADELPHIA PATHOLOGICAL SOCIETY.

SEPT. 21, 1885, the President, Dr. E. O. SHAKESPEARE in the Chair.

Dr. WILLIAM OSLER, presented specimens of

##### TENIA ECHINOCOCCUS.

This rare parasite was reared experimentally by feeding a dog with hydatids from the liver of a pig. The animal was killed about seven weeks after the feeding, when the small intestine was found to contain many hundreds of the mature tape-worms. The portion of bowel exhibited had many adherent to the mucous membrane. From the small size of the worms, only a few lines in length, they are very apt to be overlooked. Cobbold states that the only specimens procured in England have been experimentally reared. Dr. Leidy has never met the adult worm in this country. That it must occur here from the dog is very evident from the frequency with which echinococcus cysts (the larvae) are met with in the hog and other animals.

##### CYSTICERCUS CELLULOSUS.

Dr. OSLER exhibited the heart, brain, and a portion of the flesh of a pig containing the "measles," as the larvae of the *tenia solium* are called. Both organs were thickly studded with the cysts, which were also very numerous throughout the muscular system. The animal was fat and had seemed to suffer very little inconvenience. Attention was called to the cysts beneath the tongue, and to the possibility of telling whether an animal was measled by an examination of this part during life. Microscopic slides of the para-

sites were shown and a slide of a cysticercus, with a very large caudal vesicle, from the omentum, in which situation they may grow to the size of a walnut.

##### DISTOMA HEPATICUM: EFFECTS ON THE LIVER.

Dr. OSLER also showed the liver of an ox with enormous enlargement of the bile vessels and calcification of their walls, due to the chronic inflammation excited by the presence of the flukes. The main ducts were thicker than the thumb, and even the smaller tubes were hard as the stem of a clay pipe. The liver substance was wasted, but not cirrhotic. In spite of this extensive disease, the animal was well nourished. Specimens of the flukes in spirit and mounted were also shown.

Dr. WILLIAM PEPPER presented before the Society the specimens of

##### TENIA FLAVO-PUNCTATA

Described by Prof. Leidy in the *American Journal of the Medical Sciences*, July, 1884. This species has never but once before been seen and recognized, and then by Weinland, of Boston, in 1858. Both specimens were expelled from young children and averaged twelve inches in length.

Dr. PEPPER also presented the head and neck of a specimen of

##### TENIA MEDIO-CANELLATA.

It occurred in a young man. A course of starving, followed by castor oil and pelletierine, removed a portion of the worm; afterward, a repetition of the starving process without the castor oil, but with the alkaloid, brought away the entire worm dead.

Dr. PEPPER said he was particularly interested in this series; it spoke forcibly of the necessity of studying comparative pathology. The specimens were very perfect and more instructive than more highly-organized species. In practice, he had found the *T. medio-canellata* as difficult to expel as the *tenia solium*. The exhibition of the small variety, the *flavo-punctata*, taught the necessity of a careful examination of the stools.

Dr. DE SCHWEINITZ exhibited the kidneys, ureters, and bladder from a man who died after the operation of

##### LITHOLAPAXY.

The patient, aged seventy-three, had for two years previous to the operation, suffered with straining during the act of micturition, and other symptoms of hypertrophy of the prostate gland and vesical calculus. The urine contained albumen, pus, epithelium and granular casts, and had a sp. gr. of 1018. The patient's habits were intemperate. The operation of litholapaxy was performed, marked difficulty having been experienced in the introduction of the instruments. After the operation, the patient exhibited great restlessness, precordial pain, and rapid, feeble pulse. Later he became comatose, and died twenty hours after the operation, the immediate cause of death being, apparently, the formation of a heart-clot. The post-mortem examination was made about ten hours after death:—

Body well made; nothing of note anteriorly; the usual ecchymoses posteriorly. *Thorax*.—Old, pleuritic adhesions on the right side; left side free. Lungs crepitant with slight posterior congestion. Heart surrounded with fat; muscular fibres flabby; valves normal; firm, "chicken-fat" clot within right ventricle.

**Abdomen.**—Position of viscera usual; marked deposits of fat in the omentum; liver slightly enlarged, soft, but otherwise normal; both kidneys granular and containing cysts; bladder thickened and showing two spots of ecchymoses on the mucous surface. Prostate enlarged; other organs normal. Brain and membranes not examined.

Dr. TYSON thought this case added one more to the list showing the impropriety of crushing for stone when kidney disease was present. He did not know why, but under such circumstances the cutting operation was more suitable. Dr. TYSON cited the case of Louis Napoleon, as an instance of the danger of crushing in the presence of kidney disease. Dr. TYSON said, in answer to a question of Dr. Barton's regarding the kidneys, that they were contracted, though not markedly so, as there was good secreting structure left. The cysts were part of the pathological anatomy of granular kidney. He believed the cause of death to be uræmia.

Dr. G. G. DAVIS said that in such cases the post-mortem examination was in reality of the nature of an investigation. Death might be due to direct violence done the urethra, the prostate, or the bladder; or it might be due to extension of inflammation to the peritoneum, or to unknown cause, as in the present case.

Dr. DE SCHWEINITZ said that the urethra was not examined, and agreed with Dr. Tyson that the cause of death was uræmia. This was the more probable because an officious attendant, against orders, had administered rather full doses of morphia.

Dr. HENRY BEATES presented a specimen of

#### SYMPHILITIC ABSCESS AND NECROSIS OF THE TIBIA.

Removed by amputation at the middle of the thigh. The patient is a strumous man, who three years previously, had suffered from an attack of obstinate sciatica accompanied by a marked degree of muscular atrophy of the affected limb, followed by lameness. Two years later, a swelling developed at the femoral side of the gluteo-femoral crease, which opened and discharged small fragments of necrosed bone. The sinus was finally healed and fair health enjoyed for several months. Seventeen weeks ago, ostitis of the tibial head developed, followed, in a short time, by suppurative synovitis. The pus perforated the ligamentum posticum and burrowed beneath the gastrocnemius, elevating it and the posterior tibial muscular structures from the bone. Free incision evacuated this, but the destructive process continued, resulting in the formation of sinuses and complete disintegration of the joint. Hectic was pronounced, and to save life, amputation was performed on the day previous. Longitudinal section through the femoral joint and tibia discloses the extensive destruction effected in so comparatively short a time. The articulating surface of the condyles is denuded of its cartilage, and the surface of the bone is roughened. The patella is bound firmly to the trochlear portion of the condyles. The articular elements are destroyed. The head of the tibia is completely necrosed and broken down. The medullary canal of the tibia throughout its entire extent is infiltrated with pus. The surface of the bones is also the seat of the morbid process. The pus from the joint has burrowed upward beneath the internal and external vasti muscles and deprived the femur of its periosteum for a considerable distance. The anterior face of the tibia is similarly denuded, while the crest at the middle is the seat

of ulceration. At the time the disease occurred, the patient first noticed a chancre. Six weeks later, the secondary phenomena developed and were promptly met with anti-syphilitic remedies. Was the strumous disease influenced by the syphilis? The specimen was referred to the committee on morbid growths for microscopical examination, with instructions to look for tubercle bacilli, and for those said to be peculiar to syphilis.

Dr. DAVIS was desirous of knowing if the disease of the head of the tibia was due to scrofula or syphilis; the worm-eaten character of the ulcer on the tibia looked like syphilis.

Dr. CHARLES M. WILSON inquired if there had been fevers, rigors, and evidences of pyæmia in this case. It was undoubtedly one of osteo-myelitis, and in a similar case of traumatic origin which he had exhibited, rigors had been present.

Dr. JURIST asked how the presence of acute syphilis in the patient would affect the prognosis of the operation. Dr. BEATES replied that there had been symptoms of septic fever, and as the acute symptoms of syphilis had been absent for some weeks, he did not think this would move the prognosis.

Dr. LOUIS JURIST presented the larynx and trachea removed *post-mortem* from the body of a man, aged thirty-eight, a bookkeeper, who had suddenly died. He had not had syphilis. He had taken cold on Saturday and had a sore throat; on Tuesday, he chatted with the Doctor, and an examination gave no evidence of anything except ordinary pharyngitis; on Wednesday, he went to his business; on the evening of that day the doctor was sent for in haste, and on going at once, found the man dead. Nevertheless, a hurried laryngotomy was done and efforts were made to restore the heart, but without avail.

Dr. JURIST removed the larynx through the thoracic cavity. He was in doubt as to the mode of death. The lungs were fairly healthy, though cheesy on one side. There must have been an abscess present.

Dr. TYSON was surprised that marked improvement should have followed the treatment by emetics and sedatives, as the abscess must have been present; perhaps the outlying edema was subdued and the condition thus improved.

Dr. WHARTON had had no experience in such cases, but agreed with Dr. Jurist that the operation of tracheotomy, and not laryngotomy, was indicated.

Dr. JURIST was in doubt in regard to the diagnosis; it rested between perichondritis and a subsequent abscess or phlegmonous laryngitis. He was inclined to the former view.

#### THE NEW YORK ACADEMY OF MEDICINE.

STATED meeting, October 15, 1885.

THE ENTIRE INDEBTEDNESS OF THE ACADEMY PAID OFF.

Dr. F. A. CARR, on behalf of the Board of Trustees, reported that a payment of \$2,000 had just been made, which covered the amount remaining on the original mortgage of \$10,000, on the building; so that the Academy was now entirely free from debt.

THE KRACKOWIZER PRIZE FUND.

The Secretary read a letter announcing that certain friends, both lay and medical, of the late Dr. Emil

Krackowizer, an eminent surgeon of the city and a devoted friend of the New York Academy of Medicine, would present the sum of \$1,455 to the Academy: to be known as the "Krackowizer Prize Fund," on condition that it should offer every three years from the accumulated interest of this amount a prize for the best essay or book on a medical topic. The donors suggested that it should be left to the wisdom of the Council of the Academy to determine whether the prize should be awarded as a recognition of the best literary medical production of America during the previous three years, or of the most satisfactory solution of a question or problem proposed for competition. Also that the President and Corresponding Secretary of the Academy and the Presidents of the College of Physicians and Surgeons, the University Medical College, and the Bellevue Hospital Medical College, officiating at the time of the award, should constitute the Prize Committee, unless the Academy or its Council should decide differently. The communication was referred to the Council with power.

DR. STEPHEN SMITH read a paper on

THE COMPARATIVE RESULTS OF OPERATIONS IN  
BELLEVUE HOSPITAL.

As we drift with current events, he said, we but imperfectly estimate the real advance which any act or science with which we are daily familiar has made within a limited period; and there was perhaps no better place in which to test the progress of practical and operative surgery than the wards of Bellevue Hospital, which had within its walls and environments all the conditions that in modern times are regarded as unhealthful and unsanitary. It was built between the years 1811-16, on the made lands of a cove of East River, without drainage or adequate sewerage, and without regard to ventilation; while before its occupation as a hospital it had been used both as a prison and an almshouse. Its wards had, from time to time, been crowded with patients suffering from typhus and typhoid fevers, small-pox, puerperal fever, cholera and yellow fever; and although many changes had been made in its interior, yet the great and most serious defects of location and construction still remained.

The surgeons of this hospital had always ranked among the best in the city; and yet the practice of surgery here had, within a few years, undergone so complete a revolution that one of the older surgeons would scarcely realize that he was in the same institution where he had practised a decade ago. He would see with horror operations fearlessly performed that he had formerly regarded as without the pale of legitimate surgery. He would witness procedures in the after-treatment of operations which would seem to him to be fantastic, and even ludicrous. His astonishment would be extreme on finding that the first week passed without fever, and that no change in the dressings had been made. But, perhaps, the most remarkable feature of modern practice would be the rapid convalescence and final complete recovery, without complication or exhaustion, of ordinary operations, which formerly gave so much trouble and anxiety.

Whereas, before the use of anesthetics the most important general principle governing the operation was celerity, Dr. Smith said that now one thought and purpose occupied the mind of the surgeon, and that was, recovery without suppuration. Taking up the performance of operations, such as amputations, for in-

stance, he described the methods by which absolute cleanliness is now secured, in contrast to the former practice, when in the simple failure to secure ordinary cleanliness of the surface, wounds were more frequently poisoned and induced to suppurate than from any other cause. Then, having referred to the past and present methods of closing wounds and of after-treatment, he went on to say that if we followed the wounds treated by these two methods from the first to the last dressings, the contrast was remarkable. If the wound was large, fever formerly began on the second or third day, announcing suppuration, and from this date, for weeks after, the dressings were changed daily, one, two, or three times. The fever generally ran high, with consequent exhaustion and depression of the patient. Septicæmia, as now understood, was the intermediary fever of that day, and was regarded as a usual, if not a necessary, sequel of all considerable operations. Following this fever, or rather insidiously grafted upon it, were chills, fever, and profuse sweatings, now recognized as pyæmia, but then regarded as only another stage of surgical fever. Few, indeed, survived this fever; and in the diffused or metastatic abscesses revealed at the autopsy, the surgeon discovered a cause of death quite beyond his power to prevent, control, or even comprehend.

The vast change in the progress of operated cases during the past ten years, he went on to say, could scarcely be recognized. Surgical fever with all its disastrous variations, was, in practice, rare now in Bellevue Hospital. Pus, as an outcome of surgical operations, was a thing of the past. The wound was now dressed with no expectation that fever would arise, that suppuration would occur, or that the dressings would require renewal. The patient slept and ate well from the first, and the surgeons often removed the dressings only to find the wound united; a condition of affairs which was true not only of incised wounds, but equally of wounds of amputation, excision, ligation of arteries, etc.

Turning from this review of the normal stages of operations in general to particular operations, Dr. Smith said that many curious illustrations of the remarkable progress of practical surgery in this hospital were to be found; in proof of which he cited the treatment of compound fractures, amputations, excision of the larger joints, and ligation of the large arteries. If the major operations were now performed with so much success, he continued, it followed that the minor ones were correspondingly successful; a good instance of which was afforded in the improvement in the treatment of cold abscesses. Perhaps the most marked illustration of the great improvement in operative surgery in Bellevue, however, was to be found in the unvarying success which attends the treatment of simple fracture of the patella by wiring together the fragments; a procedure which embodies the very spirit and genius of the surgery of to-day, namely: boldness to audacity in the conception of an operation, and conservatism the most absolute in the method and means employed in executing it. This operation was now accepted as legitimate, and no procedure, so inherently dangerous when performed according to old methods, had ever proved more successful.

After briefly referring to the success attending gynaecological operations in this hospital, Dr. Smith said, in conclusion, that in reviewing the surgical practice

of Bellevue, it was not difficult to determine the essential feature of the present methods as compared with those of the past. Cleanliness was the one great object to be obtained in all operations. Whatever might be the final conclusion of scientific students as to the cause of putrefaction in wounds, practically it was determined that the surgeon might, with almost absolute certainty, protect an ordinary open wound from supuration. To effect this object he found that he had simply to resort to those measures which are known to secure perfect cleanliness of the wound. The agents now relied upon and found efficient were: (1) Soap and water to external parts. (3) Carbolic solutions for the instruments. (3) Bichloride solutions to all surfaces and tissues. (4) Iodoform for external dressings. The conditions regarded as essential to success might be summarized as follows: A clean operator; clean assistants; a clean patient; clean instruments; clean dressings.

## DISCUSSION.

DR. ALFRED C. POST said that he could cordially endorse the sentiments expressed by Dr. Smith, more especially in regard to the matter of thorough cleanliness. He thought there was still some room for question as to how far antiseptics, so-called, contributed to the admirable results which are now obtained in surgical practice. The great point he believed to be, perfect cleanliness and the seclusion of the wound from malign influences from without. His doubt as to the value of antiseptics had its origin in the reported experience of the renowned gynaecological surgeons of Great Britain, such as Lawson Tait and Dr. Thomas Keith, who had discarded their use. They trusted entirely to thorough cleanliness, and had even expressed the opinion that antiseptics added slightly to the mortality of such operations as they were accustomed to perform. It has to be noticed, however, that these surgeons were always careful to have their sponges and ligatures treated with antiseptic solutions beforehand. Still, they did not cleanse their hands with antiseptics, and applied no antiseptic dressings after their operations. Personally, Dr. Post said he was somewhat disposed to believe in the efficacy of antiseptics; but at the same time, he felt a little staggered by the extraordinary success of the surgeons referred to, without them. The success of Spencer Wells, who still employed antiseptics, was not as great as that of Lawson Tait and Dr. Keith. But, at all events, whatever the reason was, the fact remained that the improvement in surgical practice had been very marked.

DR. W. G. WYLIE stated that until three or four years ago, ovariectomy was not performed at Bellevue Hospital, on account of the great mortality attending the operation there. When he was an interne in the hospital in 1870 Listerism was just beginning to attract attention. It had, at all events, taught us the lesson of perfect cleanliness. He believed, however, that antiseptics were really beneficial, although it was doubtless true that their employment had been carried to excess. Every one who employed coverings of cotton-wool, which was one of the best agents which we possessed for protecting parts from deleterious influences, was, in fact, using a Lister dressing. Tait and Keith, on account of the extraordinary cleanliness which they practised, might not require antiseptics; but should their hands become contaminated in per-

forming operations or autopsies, he did not think they would hesitate to use antiseptics on their own persons. For himself, he made use of them simply as a supplementary measure; and if he was certain that he could secure absolute cleanliness without their assistance, he would not employ them either. But all surgeons engaged in active practice, are liable to contamination, and therefore he thought it was much safer not to dispense with antiseptics. Tait's recent statement in regard to these agents was simply an expression of the present reaction against them, and he thought it was likely to do great harm by rendering surgeons careless, so that they would not adopt those measures of extreme cleanliness which were essential to the highest success in practice. Dr. Wylie said, in conclusion, that when he came out of Bellevue, after his service as an interne in its wards, he was of the opinion that the whole place ought to be pulled down; but now, although there was certainly much to be desired about the arrangements of the building, he was convinced that, with the methods at present in vogue, the most excellent results could be obtained there. It was a great injustice to Lister to cry down antiseptics, as we never knew what cleanliness was until he taught us.

DR. F. V. WHITE said that he should like to inquire of Dr. Smith whether he was accustomed to get bony or ligamentous union in treating fractures of the patella in the manner described.

DR. W. M. CARPENTER remarked that the various points of Dr. Smith's paper had passed before his mind like a very pleasant panorama. He had begun to frequent the wards and dead-house of Bellevue about twelve years ago, and was perfectly familiar with the history so graphically related this evening.

What struck him particularly, in looking back over this period, was the absence at the present day from the dead-house of the hospital, of those grave internal lesions, such as surgical kidney, which used to be so common there. There was certainly a remarkable and most gratifying change in this respect, and as far as he could recollect, he had not seen a case of surgical kidney for five or six years. Such pathological conditions were now, fortunately, a thing of the past. Again, in former times, autopsies in cases in which death resulted from surgical operations were very frequent; but this was no longer the case, and all these happy results had, as all knew, followed upon the adoption of what is known as antiseptic surgery.

DR. SMITH said that he had not intended to discuss antiseptics or any theories respecting them in his paper. It was his own opinion, however, that the improvement in surgical practice which he had described, was due simply to the securing of extreme cleanliness.

In the first place, the condition of the surgeon, the assistants, the nurses, and the instruments, etc., were all carefully looked after. Especially was attention paid to the nails, which were formerly one of the most frequent sources of contamination. In the second place, the parts are always washed until thoroughly clean; and not only the parts in the immediate vicinity of the wound or operation, but, in fact, the entire person of the patient. The share that could be claimed for mere antiseptics in the good results noted was probably very slight; but at the same time they had served a most excellent purpose in stimulating us to the carrying out of these measures of perfect cleanliness. Those, therefore, who were now ridiculing antiseptics, he be-

lieved to be doing great mischief. Mr. Tait had made the statement that carbolic acid never came near his patients; but he had met with a patient of that surgeon's who had informed him that in his actual practice he did not discard antiseptics so completely as he would have us believe, and that the minutest care was always observed in regard to his ligatures, sponges, instruments, etc. If, however, the present cry were kept up against antiseptics, great carelessness would be sure to ensue, especially on the part of those who had always been opposed to their use, and, in consequence, very bad results would once more be seen in surgical practice.

In reply to Dr. White's question, Dr. Smith said that he did not know whether bony union was secured in fracture of the patella or not. The results were very satisfactory, however; and so he thought that there must be either bony union or else extremely firm fibrous union.

### Recent Literature.

*Milk Analysis and Infant Feeding. A Practical Treatise on the Examination of Human and Cows' Milk. Cream, Condensed Milk, etc., and Directions as to the Diet of Young Infants.* By ARTHUR MEIGS, M.D. Philadelphia: P. Blakiston, Son & Co. 1885. viii. 102. 8vo.

This little work, the most of which has been previously published as papers read before medical societies of Philadelphia, is a eloquent presentation of the opinion of the author that human milk only contains about one per cent. of casein, and never two to four per cent. as has been commonly asserted. It gives in full detail his process of analysis which he acknowledges "is such a tedious one, taking from four to six days to complete a full proximate analysis, that the time required to finish a large number would necessarily be very great." The conclusions are drawn from the result obtained in his analysis of ten samples of milk by his process. One of the samples was the mixed milk of twenty-seven, and another of eight women, while the other eight were each from a different woman. The ten samples thus representing the milk of forty-three women. The principal advice given in the work is that if a child is to be handled from birth, it be upon a mixture prepared in the following proportions. One tablespoonful of good average city milk, two each of the same average city cream, and of lime water, with three of a milk sugar water containing seventeen and three-quarters drachms of milk sugar to the pint. This mixture not to be increased in strength until the child is at least six to nine months of age. Such a mixture would undoubtedly be more generally found to agree with infants than any of the best known manufactured foods to be found in our markets, for it would very much more nearly imitate the composition of average woman's milk.

Dr. Poullain, in the *British Medical Journal*, recommends for constipation in young children, the use of a tablespoonful of fine bran night and morning in a cup of bread and milk. The bran is warmed in the milk and then poured on the bread.

## Medical and Surgical Journal.

THURSDAY, OCTOBER 22, 1885.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly, by CUPPLES, UPHAM & Co., Boston. Price, 15 cents a number; \$5.00 a year, including postage, to subscribers in the United States and Canada. Foreign subscribers are charged the postage in addition.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.*

CUPPLES, UPHAM & COMPANY,

283 WASHINGTON STREET, BOSTON, MASS.

### PROFESSOR VIRCHOW ON ACCLIMATIZATION.

At the recent meeting of German Naturalists and Physicians at Strasbourg, Prof. Virchow gave an interesting address on acclimatization. Hippocrates, he said, was the first to treat of the influence of the air, water, soil, etc.,—in a word, the climate—on human evolution. We moderns have done little but develop the ideas of Hippocrates; our *cosmopolitanism* is only the practical consequence of the fact that the human race may live anywhere on the globe, provided it can adapt itself to the climate of the locality.

Professor Weismann had said at that same meeting that the acquired anomalies of individuals are not transmissible to their descendants when these anomalies have been produced by a pathological process. Virchow did not share this opinion, for where is the precise limit between physiology and pathology? Where is the *fundamental* difference between the functions of the two? There is no doubt that any special alteration is transmissible; family marks were instanced. Now every alteration is abnormal, without being for that reason a *disease* in the strict sense of the term; but it is always and everywhere a change of the actual state, hence an anomaly with reference to that state.

This transmissibility, this variability, leads to the subject of acclimatization. Every new comer into a strange climate finds himself for a while ill at ease, until a constitutional adaptation is effected; but adaptation carries with it change in the organs functioning. This adaptation may be characterized by slight indisposition or severe illness. We know, however, more about the *diseases* of acclimatization, concerning which there have been important researches, than we do about the minor illnesses. But it is, Virchow thinks, just these slight indispositions that might reveal to us the mode of change of the functions, those organic alterations in correspondence with the environment which constitute the essence of acclimatization.

The principal question which now presented itself to the speaker was this: How far in the white man does the faculty of acclimatization go? What does history teach on this point?

To answer this question satisfactorily it must be

premised that "white" men are divisible into several races, indubitably different. Thus the Semites differ from the Aryans; the first undergo acclimatization more easily than the second. Likewise, the inhabitants of Southern Europe — the Spaniards, the Portuguese, the Maltese — more readily acclimatize themselves than the inhabitants of Northern Europe.

In attempting to explain this greater resistance of the people of the south of Europe to climatal changes, Virchow denied that it was owing to the fact that they live in a hot country: negroes resist badly the influence of a new climate, though this may be as hot as their own: witness the enormous mortality of the negroes of Senegal when transported to another part of the same territory.

This greater resistance of the Southern Europeans is explained by the fact that they contain more Semitic blood than Europeans of the North. "The more the Aryan blood is mitigated by Semitic, the greater the resistance to changes of climate. The first navigators and colonizers were Phœnicians. The Spanish language contains many Moorish words, and "it is certain that there is as much Moorish blood in the veins of the Spaniards as there are Moorish words in their vocabulary." On passing a certain northern limit towards the south, we find everywhere a mingling of Aryan and Semitic blood, and the more ancient and pronounced this mixture, the greater is the force of resistance against change of climate, that is, against the capability of acclimatization.

Virchow proposes to call nations of the Aryan race *pure, vulnerable* populations. For such nations there is a very limited zone to which they can become well acclimated, and this is in North America. The inhabitants of the north of France for instance, who rapidly die in Algiers, readily get acclimatized in Canada; the French Canadians are notably a hardy race.

In Virchow's estimation the Anglo-Saxons and the Germans are ill fitted for the colonization of tropical and sub-tropical countries, nor do their children thrive well there; they are like the palm trees which can be cultivated in our hot-houses, but which can never be acclimated.

The principal alteration due to climatal influences which affects persons immigrating into hot countries, is a kind of anaemia, a defect in the production or elaboration of blood. This anaemia explains the most of the troubles of acclimatization, but merits, as does this entire question of organic adaptation, a rigorous scientific examination. There is here ample scope for the best work of the naturalist and the physician.

### THREE PRIZES FOR MEDICAL ESSAYS.

WE have more than once before this commented upon the singular apathy which has of late years manifested itself among the younger graduates in medicine, in regard to prize essay competition.

There was a time when every ambitious young physician in Boston, felt an eager desire to gain the Boylston prize, and an assurance when gained that a dis-

tinct promise of future success and distinction went with it; and a review of the names of the prize winners through a long series of years shows that this promise was, in most cases, fulfilled. Now, we will not say that those who gain the prize are any less deserving than their predecessors in the first sixty years of the century, but at least those whose names are not on the list, reconcile themselves more easily to the fact.

There must, of course, be a variety of reasons, some of which may be good ones, for such a change: but we are confident that this lack of high grade competition for prizes offered must, on the whole, be interpreted unfavorably to the zeal of the younger portion of the profession. There are, it is true, more prizes offered than there used to be, but, on the other hand, there certainly are in a much larger proportion more doctors than there used to be. There undoubtedly also are more young men with the training, the leisure, and the hospital and laboratory facilities fitting them for the original work demanded by these prizes, than in former years.

The money amount of the prizes offered should in not a few of them prove of itself a considerable temptation, and evidently does in the case of the professional prize competitioner, an individual who bears the same relation to the physician that the draughtsman habitually submitting competitive plans for public buildings does to the architect.

Whatever the sum of money or distinction gained, the best reward carried with these prizes, and this is a reward which others besides the one winner of the prize may share, lies in the thorough study and mastery of some one subject, and in several of the prizes now offered the subject selected for his essay is left in a large degree to the choice of the writers, so that each may cultivate that field which is most interesting or likely to prove most profitable to him individually.

These reflections are suggested by the announcements of three different prizes which have lately attracted our attention. The Warren Triennial Prize, founded by the late Dr. J. Mason Warren in memory of his father, with an endowment fund the accumulated interest of which shall be used every three years, is to be awarded in 1886. The dissertations on some subject in Physiology, Surgery, or Pathological Anatomy should be forwarded to the Resident Physician of the Massachusetts General Hospital on or before February 1, 1886, the arbitrators being the physicians and surgeons of that hospital. The amount of the prize will be four hundred and fifty dollars, and it is open to general competition.

The prize of the Alumni Association of the College of Physicians and Surgeons of New York will be awarded at the next annual Commencement, May 11, 1886. Competition for this prize is restricted to the Alumni of the college, but the only restriction upon the choice of a subject is that, the competing essays must embody the result of *original research* upon some medical subject. The amount of the prize is five hundred dollars, and essays should be sent before April 1,

to any one of the three members of the Alumni Committee.

The Shattuck Prize of the Massachusetts Medical Society will be awarded at the annual meeting of the Society in June, 1888. The interest of the fund left the society by the late Dr. Shattuck was, for many years, largely used in defraying the expenses of the society's publications. Now, in accordance with the expressed intentions of the testator (the publications being to a greater extent otherwise provided for) the committee on publications offer a periodical prize on "The Climate and its Modifications as Influencing Health and Disease, or on any of the Diseases of the Inhabitants of New England," or on *any kindred subject*. We understand that a good deal of latitude may be attached to the words on *any kindred subject*. The competition for this prize is unrestricted—not being confined to members of the Massachusetts Medical Society—and the amount will be one thousand dollars: the essays should be delivered to the chairman of the committee on publications on or before March 1, 1888.

For the first and third of these prizes no award will be made in case no dissertation is considered worthy; but it is scarcely conceivable that the wide choice of subjects and the sums offered should not draw forth really meritorious work for all three competitions.

#### QUARANTINE INSPECTIONS ON THE NORTHERN FRONTIER OF THE UNITED STATES.

UNDER date of October 10th, and through the office of the Supervising Surgeon-General of the Marine Hospital Service, the Treasury Department has issued a circular, printed in full in another column, in which are framed "regulations for the maintenance of quarantine inspections on our Northern frontier."

In our issue of October 8th, we commented upon the measures taken up to that date by the Treasury in response to the request of the Governors of some of the States, to which New York may now be added.

The system of inspection then in force was personally investigated by the Secretaries of the New Hampshire and Maine Boards of Health, Drs. Watson and Young, and we believe was not found in all respects satisfactory by them, the defects being indicated to the authorities at Washington, and probably by this time they have been modified or corrected as far as circumstances permit.

In our previous comments our readers were warned against an exaggerated confidence in these quarantine inspections, exaggerated whenever tempting them to relax individual or local vigilance. Now again—although the inspections are made with more care than at first—we wish to reiterate these warnings. Small-pox is still very active in Canada and is not likely to diminish with the advent of cold weather. We hold now as we have always held, that no system of quarantine or of inspection, however good, will, under such circumstances, exclude the disease from a neighboring country. The rumors in regard to the appearance of

small-pox at several points in Burlington, Vt., give emphasis to this statement.

Fortunately, in the present emergency each individual and each community has the elements of protection largely in its own control, and "quarantine inspection"—though otherwise useful—will do more harm than good if people are encouraged in a false sense of security to the neglect of other precautions.

#### MEDICAL NOTES.

BOSTON.

—The will of the late Mary G. Perkins contains bequests of \$10,000 each to the New England Hospital for Women and Children and the Children's Hospital, and \$5,000 each to the Boston Children's Friend Society and Notre Dame Academy, Roxbury. Her books and the proceeds of certain diamonds are bequeathed to the Newsboys and Boothblacks' Reading Room, and the trustees of the City Hospital are made residuary legatees. The funds so received to be applied to the purchase of medical books, and of artificial limbs and other surgical appliances for patients leaving the hospital.

—The Board of Registration in Pharmacy organized Oct. 6, electing H. M. Whitney, of Lawrence, President, and S. A. D. Shepard, of Boston, Secretary. The Board has issued circulars to the druggists of the State, calling attention to the provisions of the statutes, and announcing that applicants for examination may appear on the first Tuesday of January, May, or October, and on other days which may hereafter be appointed. Applications for registration under Section 3 of the law, may be sent at once to the Secretary, and all should be in previous to Dec. 31. A printed card or label should be sent with the application, in order to avoid possible error as to the name on the certificate to be issued. The Board understands that to begin business, or to have had a practical experience of three years, a part of which is acquired after Jan. 1, 1886, does not come within the intent of the law. No certificates will be sent out until after the regular meeting of the Board, Jan. 5, 1886.

NEW YORK.

—Health Officer Smith has made a report to the Quarantine Commissioners in which he announces the success of the recent experiments in disinfecting rags by the "sulphur vacuum" process. The object was to determine whether the agent would penetrate to the centre of the bale of rags and destroy the germs placed therein, the bale being in a vacuum when the sulphurous acid was introduced. The first experiment and its results were given in a previous communication. The report states that the second experiment, made on the 25th of September last, in the presence of Drs. Briggs and J. B. Taylor, of New York, Dr. Sternberg, of the United States Army, and other experts, was with the purpose of eliminating the possible errors of the tests made on the 26th of August. The bale used on this occasion did not represent the largest and heaviest bales imported; and so the experiments were re-

peated on the 2d of October. In both series of experiments a vacuum representing twenty-eight inches was produced, and a pressure of twenty-six pounds from the introduction of sulphurous acid; while the exposure of the germs (cholera bacilli and others), and vaccine virus used was about thirty minutes. Dr. Briggs reported that no development of any kind had occurred in any of the cultures made after the exposure to gas at the end of fourteen days, with the exception that after ten or twelve days there was development of a bacillus that liquified the gelatine; but when this was tested by plate cultures, only the rod bacillus was found—presumptive proof that it had been introduced after the exposure of the sulphurous acid in the course of the manipulation at the laboratory. (This was after the experiment of September 25th.) The results of that of October 2d are thus given: "No development of any kind in any of the cultures made by the germs exposed."

In respect to the result of the exposure of vaccine virus in the bales of rags under the same conditions and at the same time that the various germs were exposed, Dr. J. B. Taylor reported that he collected virus the morning of the experiments in each instance, charging six points that were exposed to the gas with the germs. The same number of points were charged from the same calf at the same time that those were which were exposed to the sulphurous acid. He vaccinated two children in one family, each on the left arm, with the fumigated virus, and each on the right arm with the non-fumigated. The former failed in both instances, while the latter were both successful. With the remaining points four babies were vaccinated, all of which were unsuccessful. Four were also vaccinated with the non-fumigated, all of which were successful. On the 2d of October a similar test was made with the same number of vaccine points, taken and treated in exactly the same manner. On the following day, six infants were vaccinated with the fumigated virus, and all were failures, as before; while of the six vaccinated with the non-fumigated virus, four were failures and two were successful.

Dr. Smith states that the conclusion in his mind after these experiments, conducted as they have been, with much care and labor, is, that the disinfection of rags by the "sulphur vacuum" system can be efficiently accomplished; and that an arrangement by which one or any number of bales of rags can be introduced into a receptacle in which a vacuum of twenty-five inches or upward is produced, followed by a pressure of twenty-five pounds or upwards, by the introduction of sulphurous acid, and the continued exposure of the rags under these conditions for twenty-five minutes, may be considered as satisfactory disinfection of such rags. At the meeting at which Dr. Smith's report was presented, the Quarantine Commissioners passed a resolution to the effect that it was the sense of their Board that the sulphur process for disinfecting rags arriving at the port of New York was satisfactory to its members.

—At the October meeting of the Society of Medi-

cal Jurisprudence and State Medicine, Dr. Wm. M. McLancy read a paper on the subject of cremation, in the course of which he called attention to the fact that whenever cholera has visited New York, it has always hovered around Trinity Churchyard. He further stated that the oldest local physicians claim that it is impossible to raise children on the ground floor of Washington Square, which was formerly used as the Potter's field.

—The report of Dr. John T. Nagle, Registrar of Vital Statistics, to the Board of Health, shows that for the quarter ending September 30, there were 9,950 deaths in the city, a decrease of 38 as compared with the corresponding quarter of 1884. Among the deaths were 7 from small-pox, 74 from measles, 55 from scarlatina, 259 from diphtheria, 144 from croup, 186 from whooping-cough, 3 from typhus fever, 100 from typhoid fever, 45 from cerebro-spinal meningitis, 116 from malarial fever, and 2,527 from diarrheal diseases.

—A new hospital, containing thirty beds, has been opened by the city at Gouverneur Slip. The visiting surgeon is to be Dr. O. J. Ward, and the annual surgeon, Dr. J. D. Odell.

—Diphtheria has broken out in Newburgh, on the Hudson, and quite a number of cases have been reported to the Health officer during the past week. Thus far there have been several fatal cases, five of them having occurred among the pupils of one public school; the superintendent will close this. Two cases have been reported among the pupils of another public school also.

### Miscellany.

#### A CIRCULAR REGARDING SMALL-POX IN CANADA.

UNDER the authority of an act approved April 29, 1878, entitled "An Act to Prevent the Introduction of Contagious or Infectious Diseases into the United States," a circular has been issued to the medical officers of the Marine Hospital Service, custom officers and others concerned, calling attention to the prevalence of the contagious and infectious disease of small-pox in Montreal and other places in the Dominion of Canada, and promulgating the following regulations:—

All vessels arriving from ports in Canada, and trains of cars and other vehicles crossing the border line, must be examined by a medical inspector of the marine-hospital service before they will be allowed to enter the United States, unless provision shall have been made by State or municipal quarantine laws and regulations for such examinations. All persons arriving from Canada by rail or otherwise must be examined by such medical inspector before they will be allowed to enter the United States, unless provision has been made for such examinations as aforesaid. All persons coming from infected districts, not giving satisfactory evidence of protection against small-pox, will be prohibited from proceeding into the United States until after such period as the medical inspector, the local quarantine or other sanitary officer duly authorized, may direct. Inspectors will vaccinate all unprotected persons who desire or are willing to submit to vaccination, free of charge. Any such person refusing to be vaccinated shall be prevented from entering the United States. All baggage, clothing and other effects and articles of merchandise coming from the infected districts and liable to carry infection, or suspected of being infected, will be subjected to a thorough disinfection. All persons showing evidence of having had small-pox or varioloid, or who exhibit a

well-defined mark of recent vaccination, may be considered protected; but the wearing apparel and baggage of such protected persons who may come from infected districts or have been exposed to infection, will be subjected to thorough disinfection, as above provided.

Customs officers and United States medical inspectors will consult and act in conjunction with authorized State and local health authorities, so far as may be practical, and unnecessary detention of trains or other vehicles, persons, animals, baggage or merchandise will be avoided so far as may be consistent with the prevention of the introduction of diseases dangerous to the public health into the United States. Inspectors will make full weekly reports of services performed under this regulation. In the enforcement of these regulations there shall be no interference with any quarantine laws or regulations existing under or to be provided for by any State or municipal authority.

JOHN B. HAMILTON,

Supervising Surgeon General United States Marine Hospital Service.

Approved—

DANIEL MANNING, Secretary of the Treasury.

Approved—

GROVER CLEVELAND, President.

## Correspondence.

### THE QUESTION OF A VITAL PRINCIPLE AGAIN.

MR. EDITOR.—I must ask permission to trespass once more on your columns that I may point out what I believe to be the fallacies of Dr. Dwight's last communication.<sup>1</sup>

Dr. Dwight complains that I have confined myself to simple assertion without attempting to show the fallacy of his argument. If he will read once more what I wrote I think he will notice that I attempted to show successfully or unsuccessfully, that his argument was founded on a *petitio principii*, that it broke the Newtonian canon by which we are forbidden to assume the existence of new causes until the inadequacy of existing ones is shown, and I then called attention to a possible explanation, which is gradually being accepted by the leading scientific minds.

I am sorry that to this explanation Dr. Dwight has thought fit to make no reference whatsoever.

In his last communication, Dr. Dwight only restates his former argument, but I am glad to say he has put it in so much more tangible and definite a shape, that it is easier to deal with. In order to be as brief as possible I will come to the point at once.

"My proposition," says Dr. Dwight, "is stated in the following syllogism:—

"Essentially contradictory phenomena (like any other effects) cannot have a common cause.

"The phenomena of living and non-living matter are essentially contradictory, therefore they cannot have a common cause."

Here Dr. Dwight speaks plainly and without ambiguity. "The validity," he continues, "of the second premise, that vital and non-vital phenomena are contradictory<sup>2</sup> is, I conceive, the point at issue." According to the form of argument he has adopted, I agree with him entirely. He then goes on to enumerate six different points in which "living and non-living matter differ essentially." Space will not permit me to consider each of these six separately, but it will be sufficient to take the fifth as being one of the most important and curial. "The same fallacy underlies all the others.

"(5) *Non-living matter* cannot produce its kind. *Living matter* can." Now as Dr. Dwight truly says, here is a point in which living and non-living matter *differ* essentially; but the mistake he makes is in not seeing that however much they may *differ* they do not *contradict* one another. "This is the point at issue." Now it must be evident that two phenomena may be totally and radically different, but whether they *contradict* one another is a second question. Essentially different phenomena may not only be due to different causes but be the effect of the same cause; what, for example, is more different than the visual vibra-

tions of a tuning fork and a musical sound? Yet we know that both are only different modes of apprehending the same activity.

Two phenomena, on the other hand, may be said to be contradictory when they cannot exist under the same conditions at the same time. The phenomena of light are contradictory to darkness; a match cannot be luminous and non-luminous at the same time; the ground cannot be dry and wet at the same instant, and therefore we may correctly conclude that these phenomena being contradictory cannot have the same cause.

Now how does the fact that living matter reproduces *contradict* non-living matter which does not reproduce. We may say it has additional properties and functions, if you like; the vital functions are something which living matter possesses in addition to those of non-living matter; but how does one exclude the other? On the contrary, living matter possesses the properties of living and non-living matter. There is nothing contradictory in the fact that a tree grows and a tree has weight; or in the growth of a tree and the absence of growth of a stone, or if there were it would not necessarily show a difference of *kind* in the cause as it might be of *degrees*.

When we see that one piece of matter, as a lump of albumen, has one set of properties, called physical, and another piece of matter, a lump of protoplasm has, in addition to these, others called vital, there is nothing in the vital properties which *contradict* the physical, for both can exist at the same time under the same conditions. So that *so far as contradiction is concerned* there is nothing to indicate that the same kind of "forces" which produce the one do not produce the other. Whether this is or is not the case, must be settled on other considerations. We may not see *how* the forces, which produce physical phenomena, may also produce vital phenomena, but this may be only due to the imperfections and limitations of human knowledge, and until the inadequacy of all other explanations is proved we have no right to deny *that* it is the case and to assume the existence of super-material agents. It may be that vital and non-vital phenomena are not the effects of the same kind of activities, but if so, it is not shown by any contradiction that exists; it is only a question of capacity.

I will now state once more what I believe to be the real question involved in this matter of a vital principle. As I have already stated it at sufficient length in my first communication, I cannot be expected to more than indicate it again, notwithstanding Dr. Dwight's omission of all reference to it.

"Are the unknown Realities which underlie the physical properties of the inorganic world of the same nature as those which underlies the functions of the organic world?" This is my judgment to the real question at issue. For my part, I believe that an affirmative answer should be given. This same view has been expressed by Mr. Spencer, who has argued that, "Consequently, the final outcome of that speculation commenced by the primitive man is that the power manifested throughout the universe distinguished as material, is the same power which in ourselves wells up under the form of consciousness." This was the view taken by the late Professor Clifford,<sup>3</sup> and has been held by various other able thinkers. It is the view toward which I believe the scientific world is slowly drifting.

Dr. Dwight's criticism on "*primum facie* evidence," I do not think call for extended notice, as I am both to believe that on mature reflection he would still maintain them, and I am unwilling to hold him responsible for what I believe to be a merely temporary mental deception, to which any one is liable. On the other hand, there is something naive in characterizing my refusal, to discuss his second argument as an evasion, because, I suppose, I have not the rashness to discuss within the limits of a single paragraph, so extensive a subject as the relation of the mind to the body, upon which volumes have been written. As Dr. Dwight himself says, that "truly enough it would take too much space," evasion would hardly seem to be the correct term.

<sup>3</sup> Nineteenth Century, January, 1884.

As to the third argument, the freedom of the will, no one agrees more heartily than I do with Dr. Dwight, that we are all free to act as we please; that a man is "free to reply to an adversary or not." This is a fact which any one can prove for himself as often as he pleases. But I believe it also to be true, that, in whatever way we do act, we are impelled by the strongest motives. Whether this is a "freedom of the will" or not is merely a question of terms; and the possession of this "freedom" is as compatible with that theory of consciousness, which, I maintain, is the outcome of modern scientific speculation, as it is with a spiritual entity. Therefore the argument from the "freedom of the will," is either one of terms or has no bearing on the subject.

Dr. Dwight, in a postscript, quotes Mr. John Fiske in apparent support of his position. I fear that Dr. Dwight has allowed himself to be unwittingly misled by a paragraph or two of a popular essay. It is a very dangerous thing to gather a writer's views for such abstruse subjects, without reading all that he has to say. If Dr. Dwight has read Mr. Fiske's other works, especially his "Cosmic Philosophy,"<sup>4</sup> I think he never would have invoked that writer's authority in favor of a vital principle. I know

that it is very easy to miss the point of a writer's argument. But it seems to me that to charge Mr. Fiske with maintaining the existence of a vital principle, in anything like the sense in which it is employed by Dr. Dwight — that it was something in addition to and distinct from matter — is very much like accusing the Pope of Rome of atheism, or J. S. Mills of having been an advocate of protection.

In conclusion I may say one word more. Dr. Dwight seems to feel personally aggrieved because I have criticized his opinions, with the same freedom which he used toward the views of those who do not agree with him. While I am sorry if my remarks have wounded him, I think the candid reader will say that one who is thus sensitive to criticism should treat the opinions of others with respectful consideration at least. If there is anything in Dr. Dwight's letter which savors of personal rather than logical criticism I have no desire to make reference to it here.

Very truly yours,

MORTON PRINCE, M.D.

[With this reply from Dr. Morton Prince the editor begs to take leave for the present of the Question of a Vital Principle. — Ed.]

Population by State Census, of May 1st, 1885.

Deaths reported 1,511; under five years of age 563; principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrhoeal diseases) 294, consumption 218, lung diseases 132, diarrhoeal diseases 105, diphtheria and croup 89, typhoid fever 12, malarial fevers 28, whooping-cough 20, scarlet fever 10, cerebro-spinal meningitis seven, measles three, erysipelas three, small-pox one, puerperal fever one. From malarial fever, New Orleans 16; New York eight, Baltimore four. From whooping-cough, New

York 14, Baltimore two, Philadelphia, Boston, New Orleans and Fall River one each. From scarlet fever, Philadelphia six, Boston two, New York and Fitchburg one each. From cerebro-spinal meningitis, Philadelphia three, New York and Fall River two each. From measles, Philadelphia, Boston, and New Bedford one each. From erysipelas, New York, Philadelphia, and Boston one each. From small-pox, New York one. From puerperal fever, Philadelphia one.

Cases reported in Boston: scarlet fever 30, diphtheria 29, and typhoid fever 28.

The meteorological record for week ending October 10th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole of the United States Signal Corps:—

Week ending	Barometer.	Thermometer.				Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM OCTOBER 10, 1885, TO OCTOBER 16, 1885.

IRWIN, B. J. D., assistant medical purveyor and lieutenant colonel. Ordered from Department Arizona to New York City, for temporary duty in charge of medical purveying depot at that place, relieving Captain Henry Johnson, medical storekeeper. S. O. 233, A. G. O., October 10, 1885.

ADAIR, GEO. W., assistant surgeon and captain. Leave of absence extended one month. S. O. 232, A. G. O., October 9, 1885.

MOREIS, EDWARD K., assistant surgeon and first lieutenant (recently appointed). Ordered for duty in Department Missouri. S. O. 231, A. G. O., October 10, 1885.

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE FOR THE WEEK ENDED OCTOBER 10, 1885.

BAILMACHE, P. H., surgeon. To proceed to Tuckerton, N. J., as inspector, October 7, 1885.

ASTIN, H. W., surgeon. To proceed to Albany, N. Y., on special duty, October 6, 1885.

GASSAWAY, J. M., surgeon. To examine surfmen at Ellsworth, Maine, and other parts of First District, Life Saving Service, October 9, 1885.

#### OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING OCTOBER 17, 1885.

BALDWIN, L. B., past assistant surgeon. Detached from Naval Hospital, Philadelphia, and ordered to Navy Yard, Mare Island.

DICKINSON, D., surgeon. Detached from Naval Hospital, Mare Island, and ordered to Training Ship "Portsmouth" as relief to Surgeon A. M. Moore.

MOORE, A. M., surgeon. Detached from Training Ship "Portsmouth" and wait orders.

SHAFER, JOSEPH, assistant surgeon. Detached from Receiving Ship "St. Louis," and ordered to Naval Hospital, Philadelphia, as relief of passed assistant surgeon Baldwin.

HESTER, F. A., assistant surgeon. Detached from United States Steamship "Minnesota," and ordered to the "Tennessee" as relief of passed assistant surgeon Nelson H. Drake.

DRAKE, NELSON H., passed assistant surgeon. Detached from the "Tennessee," 31st inst., and wait orders.

#### DEATHS.

Died in Worcester, Mass., October 17, 1885, William Workman, M. D., M. M. S. S., aged eighty-seven years.

#### SOCIETY NOTICES.

NORFOLK DISTRICT MEDICAL SOCIETY. A stated meeting will be held at Rockland Hall, 2343 Washington Street, Roxbury, on Tuesday, October 27, 1885, at 2 P. M. The Board of Censors will meet at 1 P. M. Order of Business: Reading of records, reports from committees; election of nominating committee, incidental business. Communications: The Antiseptic Method in Surgery, W. P. Bailey, M. D. The discussion will be participated in by W. C. B. Fitch, M. D., and E. F. Dunbar,

M. D. A Demonstration of the Rectum, illustrated by drawings and casts, Walter J. Otis, M. D.

S. ALLEN POTTER, M. D., Secretary.

#### AMERICAN ACADEMY OF MEDICINE.

The Ninth Annual Meeting of the American Academy of Medicine will be held at the New York Academy of Medicine, No. 12 West 31st Street, New York, Wednesday and Thursday, October 28 and 29, 1885. Wednesday, October 28, 3 P. M., Reading of Papers: "The Study of Medicine as a Means of Education." By Robert Lowry Sibbet, A. M., M. D., of Carlisle, Pa. "Medical Supervision in Student Life." By Charles McIntire, Jr., A. M., M. D., of Easton, Pa. "Western North Carolina as a Health Resort." By Henry O. Marcy, A. M., M. D., of Boston, Mass. "The Importance of Climatology Considered as a Regular Branch of Study in Medical Colleges." By E. H. M. Sell, A. M., M. D., of New York. At 8 o'clock P. M. address by Albert L. Gilson, A. M., M. D., United States Navy, President, on "What is Medicine?" Thursday, October 29th, 10 A. M., "Medical Evidence." By Thomas J. Turner, A. M., M. D., Ph. D., Medical Director United States Navy. "Report on Laws Regulating the Practice of Medicine in the United States and Canada." By Richard J. Duglison, A. M., M. D., of Philadelphia, Pa., and Henry O. Marcy, A. M., M. D., of Boston, Mass. "Health Officers, Ancient and Modern." By Benjamin A. V. A. M., M. D., Secretary of the State Board of Health of Pennsylvania. "Microorganisms and their relation to Disease." By Samuel N. Nelson, A. B., M. D., of Cambridge, Mass. "Observations on the Relation of Bacteria to Certain Puerperal Inflammations." By Ernest W. Cushing, A. B., M. D., of Boston, Mass. "Medical Licenses and Medical Honors." By Edward Jackson, A. M., M. D., of Philadelphia, Pa. "The Physician and His Patient." By John D. McKelly, A. M., M. D., of Utica, N. Y. "Physicians of Delaware in the Eighteenth Century." By Lewis P. Bush, A. M., M. D., of Wilmington, Del. The annual collation will take place on Wednesday Evening, immediately after the President's address. Fellows desiring to participate will please forward two dollars to Dr. L. Duncan Bulkley, No. 4 East 35th Street, New York.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.—The Semi-Annual Conventional Meeting of the Society will be held at the Hall, N. E. Cor. Thirteenth and Locust Streets, on Thursday evening, October 22, 1885, at 8 P. M. Dr. J. Collins Warren, of Harvard Medical School, will address the Society on "A Comparison of the Changes in Arteries after Ligature and in the Ductus Arteriosus and Unligated Arteries after Birth."

#### NEW YORK STATE MEDICAL ASSOCIATION.

The Second Annual Meeting of the New York State Medical Association will be held November 17, 18 and 19, 1885, at the Murray Hill Hotel, Park Ave., 40th and 11th Sts., and November 20, 1885, at the Carnegie Laboratory, 338 and 340 East 26th St., New York City.

#### BOOKS AND PAMPHLETS RECEIVED.

Manual of the Diseases of Women, being a Concise and Systematic Exposition of the Theory and Practice of Gynecology for Use of Students and Practitioners. By Charles H. May, M. D. Philadelphia: Lea Brothers & Co. 1885.

Epitome of Diseases of the Skin, being an Abstract of a Course of Lectures delivered in the University of Pennsylvania during the Session of 1883 and 1884. By Louis A. Duhring, M. D. Reported by Henry Wile, M. D. Philadelphia: J. B. Lippincott Company, 1886.

## Original Articles.

ON THE TREATMENT OF LUPUS BY PARASITICIDES.<sup>1</sup>

BY JAMES C. WHITE, M.D.,

*Professor of Dermatology in Harvard University.*

It may be stated without exaggeration that the announcement of the title of my communication, had it been made at any meeting of the association previous to the last one, would have been received with amazement, if not with incredulity; and yet to-day it is entirely needless to offer you any explanation of my reasons for presenting this subject to your consideration. The revolution in their views of the etiology of the so-called chronic infectious diseases among dermatologists during the past few years, unparalleled in the history of the progress of medicine, and the unanimity with which it has been accepted independently of schools and past prejudices, furnish the strongest proof that it is based upon no mere theory, or the power of a passing novelty of opinion, but upon sound observation of facts.

I may be pardoned if I very briefly, although needlessly before this society, recall the evidence by which this change of opinion concerning the nature of lupus has been accomplished. The French school of dermatology has long maintained that lupus is a scrofulide, basing its belief upon clinical connections and anatomical resemblances, and this opinion was also held to a limited extent by writers of other nations. Within the last decade the close mutual relationship of the two affections has been more generally recognized. During this period it has been demonstrated by Koch that tuberculosis is a bacillus disease; that one and the same bacterium is constantly present in active tubercular tissue; that the inoculation of such tissue in animals produces in them tuberculosis; that the inoculation of the bacillus itself, isolated and purified by repeated culture, also produces tuberculosis; and that the tissue changes in so-called scrofulosis, as well as in tuberculosis, are the direct result of the irritating presence of the tubercle bacillus. These points established, their pathological significance in relation to the etiology of lupus was soon recognized, and investigation opened. Demme was the first to discover the presence of bacilli in lupus in 1883. Since then numerous others, although their observations were at first largely negative in results owing to imperfect methods, Pfeiffer, Cornil and Leloir, Köbner, Doutrelepon, Koch, and others, have demonstrated the existence of a bacillus, identical with that in tubercle, in lupus tissue of the integument, of bone, of lymph glands, and in pus beneath its crusts, although its growth is more sparse and apparently feebler than in other forms of tuberculosis. Inoculation of lupus matter by many experimenters into the tissues and cavities of various animals has given rise to forms of tuberculosis in the same, with the accompanying growth of tubercle bacilli. The bacillus from lupus tissue has been cultivated by Koch for sixteen months, and in these successive cultures has retained its apparent identity with that of tubercle. Repeated inoculations with such isolated growths by him has always resulted in the production of all the various forms of local and general tuberculosis, and similar results have been obtained by many

other observers. The introduction beneath the skin of the lupus bacillus by Leloir was followed by the development there of true scrofuloderma in one instance.

Let us briefly consider now, how far this most satisfactory experimental proof of the pathological identity of lupus and tuberculosis is supported by our knowledge of their clinical relations. The common occurrence of lupus in so-called scrofulous subjects, or, in other words, with tuberculosis of the glands, joints, or bones, or with milder forms of the latter, has long been recognized, but recent analysis of extensive series of cases has shown this association to be much more frequent than had been supposed, the ratio varying from thirty to sixty per cent. in the returns of different observers. The direct development of lupus upon old lesions of scrofuloderma has been not infrequently noticed. General milary tuberculosis has in several instances followed extensive mechanical operations upon lupus, as scarifications, by which process bacilli might readily be introduced into the cutaneous circulation for diffusion throughout the system, as if by intentional multiple inoculation. Finally, now that careful attention has been directed to this point, it has been ascertained that the termination of lupus in tuberculosis of the lungs occurs as often as six to fifteen per cent. in the experience of different observers.

This certainly shows a very intimate association of these forms of disease, hitherto regarded as well defined individual processes. But why is it that this individuality is so sharply observed, and that tuberculosis of the skin, scrofuloderma, and lupus do not resemble each other more closely or undergo mutual transformation as a rule rather than as the exception? For reasons not yet understood; but this ignorance of the laws of bacterial life, dependent upon insufficient observation, should not be used as evidence against the identity in nature of these affections, for by the same reasoning quite as diverse forms of other diseases, the unity of which no one doubts, might be separated as distinct disorders. In leprosy and in syphilis, for instance, we have a far greater diversity of tissue change, and as various and well defined varieties of clinical expression, in the latter in fact far greater differences. It seems, indeed, to be a characteristic feature of these organisms, this capability of so impressing human tissues, that they shall express their resentment of the irritating presence of the former by the greatest possible diversity of lesions. In the prototypic manifestations of the syphilitoderma, and in the multiplicity of tissue changes in the deeper structures of the body in the same disease, we have the culmination of this power of bacilli. In leprosy and tuberculosis we have a longer period of incubation, a slower growth, a much more restricted spread, and a greater uniformity of tissue change, but in all three of these every portion of the economy may in time become involved. It is probable that the tubercle bacillus finds an uncongenial soil in the cutaneous tissues; at any rate it spreads from its primary point of inoculation or manifestation but slowly as a rule, and is found but sparsely in lupus matter. The persistency of its growth, however, is wonderful, as it may continue to occupy a very restricted field throughout the long lifetime of its host. This tendency to confine itself within very limited areas of the corium, and the very slow rate of its progress there, even when it assumes a serpiginous type, furnish the most consist-

<sup>1</sup>Read at the meeting of the American Dermatological Association, Aug. 26, 1895.

ent reason for the usual preservation of its clinical form, and the escape of the system from general inoculation. This is no more remarkable than the usual confinement of the bacillus to the pulmonary tissues in tubercular consumption, or to the glandular structures for indefinite periods in scrofulosis. Students of morbid anatomy have many times solved to their own satisfaction the mystery of lupus disease, and in this or that histological element of tissue change have discovered the individual secret of its being, but wider investigations have shown that these were in no way peculiar to it, and that the products of chronic inflammatory disturbance were all that they had found. All the while lay there unseen and unsuspected the foreign elements of evil, which remained for the investigators of a very different training to disclose. So in discussing the peculiarities of tuberculosis in its various forms, we may not apply the ordinary methods of reasoning employed in departments of pathological anatomy; we have to deal with the attributes of plant life and are entering the realm of vegetable physiology, in which we have nearly all our knowledge to gain.

Starting then upon the basis that lupus is a form of tuberculosis of the skin, and that it consists of chronic inflammatory changes in its tissues produced by the presence of a bacillus, we are to consider what effect this discovery of its parasitic nature may have upon its treatment. It is evident that if we could bring in contact with the bacteria any substance which, without injuring the animal tissues, will destroy the life of the former, we shall accomplish in a simple and rational manner what surgery has always been endeavoring to effect by all conceivable means of therapeutic art, characterized in the main by violence and suffering, and with most unsatisfactory results. The endless succession of new remedies in the history of its treatment is conclusive evidence of the inefficiency of all, of the necessity of something better. The lack of any specific internal remedy is universally acknowledged.

It may be interesting to consider how far the action of means, hitherto the most successful in results, confirm our present view of the pathology of lupus. In the first place all mechanical measures, which form the final resource in so large a proportion of cases, demonstrate that in removing the products of the disease, or lupus matter, we wholly or largely get rid of its essence or cause, or, in other words, that we are dealing with a local and not a constitutional affection. The knife and scraper should be radical in their action, if thoroughly enough handled, but the former cannot be employed over extensive areas, and the latter is necessarily a surface instrument. They may, and do in a crude way, remove the bulk of the bacillus or lupus growth, but they are not searching enough in their action. The knife, as a scarifier, probably owes its more or less favorable results to the washing out to the surface of bacilli through the free hemorrhage which follows, but the remedy has never given satisfaction in my hands, and, as already stated, has proved in some instances to be a most mischievous operation. The destruction of the diseased growths by heat would ensure, of course, that of the vegetable organisms they contain, and the same may be stated with regard to most of the caustics so successfully employed. Of some of the milder forms of remedies thus designated, and of a great number of so-called chemical agents, it may be said that we know but little

of their mode of operation; so far as they are operative it cannot be stated that it may not be due to their parasitocidal action. This leads us to the question:

What is a parasiticide? As employed in medical language up to recent date the term embraced (in addition to its application to animal parasites) all remedies which checked or destroyed the growth of vegetable life parasitic upon man when brought in contact with it. Practically it included the substances ordinarily employed in the treatment of the mycoses of the skin. Among them were some which were also widely used in the destruction of low forms of vegetable growths in other than human forms of parasitism, and to control various fermentative processes dependent upon the presence of similar organisms. More recently, since investigations have been carried on so successfully into the relationship of still milder forms of vegetable growths to far more important diseases of animal life, the field of applicability of such remedies has been widely extended, and systematic studies have been made with regard to the degree of destructive action of many substances upon them. As the result of careful experimentation, Koch has tabulated the comparative activity of some of the best known of these agents, as follows:

corrosive sublimate,  
chlorine water,  
bromine water,  
iodine water,

and recommends the sublimate as the most destructive of bacterial life.

Buchholz found that the development of bacteria in a modified Pasteur's fluid was prevented by the following agents in varying degrees of concentration:

by sublimate, 1 part in 20,000;  
by benzoate of soda, 1 part in 2,000;  
by salicylic acid, 1 part in 666;  
by carbolic acid, 1 part in 200.

As will be seen, among the most deadly of these are those which have long been in use as the most successful parasitocides in the treatment of the cutaneous mycoses, preparations of mercury, iodine, carbolic acid, etc., and with the action of which upon the skin we were well acquainted.

In January, 1884, Doutrelepon published<sup>2</sup> a report of the treatment of several cases of lupus by the application of solutions of corrosive sublimate, and immediately afterwards I repeated the experiment in cases of the disease then under my observation. Since then several mercurial preparations have been employed against the disease, and the action of other parasitocides upon it has been tested by dermatologists, particularly to be mentioned sulphurous acid and salicylic acid. Very successful results have been reported by competent and reliable observers with these remedies alone, and as they were purposely used in all instances in such weak forms as not to cause any irritation, far less destruction of the animal tissues, it is fair to conclude that their action was in consequence of their parasitocidal properties.

I will briefly report the cases under my own observation during the past eighteen months. The first nine were out-patients at the Massachusetts General Hospital.

CASE 1. A man of Irish descent, thirty years old. The disease had existed since childhood upon the left arm, progressing gradually in a serpigineous form, and

<sup>2</sup> Monatsheft für Prakt. Dermat. Bd. iii. No. 1.

leaving considerable areas of scar tissue above and below the elbow. When first seen there remained two quite large ulcerative patches upon the arm, covered with thick crusts, and numerous large and small tubercles, more or less softened but not denuded. The right ear was generally thickened and exfoliating, and presented a few small tubercles. A solution of bichloride of mercury, a grain in an ounce of water, was applied every morning and evening for half an hour upon thin compresses kept constantly wet. After three or four weeks of this treatment the tubercles gradually shrivelled up and sank down to the level of the general surface, and lost their dark-red color. The crusts fell off, and, after forming once or twice slightly, ceased to be re-established, and gave place in some six or eight weeks to a thin, exfoliating epidermal covering. At this stage of advanced improvement the patient ceased to attend my service.

CASE II. A girl of fourteen years. The disease was of two years' duration. It occupied considerable portions of the cheeks, lips, nose, and extended within the cavity of the nostrils, and was mostly in a crusting ulcerative condition. After a preparatory treatment of the ulceration by a wash, tartrate of iron and potash  $\mathfrak{ss}$ , water  $\mathfrak{o}$ , and a boracic acid ointment for two weeks, a wash of corrosive sublimate, two grains in an ounce of water, was applied, as in Case I, for a short time, during which some of the ulcers healed, but the patient escaped from my observation too soon to allow the action of the remedies to be properly estimated.

CASE III. A girl, aged eighteen, from New Brunswick. The disease was of six years' duration. She had had hip disease in early childhood. The upper portion of the right cheek was largely occupied by scattered tubercles of various sizes, several of which were soft and covered with scales. There was no ulceration. The solution of corrosive sublimate was applied for an hour in the morning, and in the evening the tubercles were thickly covered with an ointment, Hydrarg. bichlor. gr.ii, aëq.  $\mathfrak{ss}$ . After three weeks of this treatment the tubercles had almost wholly disappeared, leaving only dull red macules to mark their former seat.

CASE IV. A boy, six years old, native of Boston. The disease had begun upon the edge of the nostril a year previously and had rapidly spread until the integument of the lower three-fourths of the nose was in a state of active ulceration, covered with thick crusts. It was greatly swollen. There was an older patch of the disease upon the arm, presenting scar tissue and a few indolent tubercles. One of the glands upon the side of the neck was in a state of "scrofulous" induration and enlargement. The bichloride wash was applied to the nose and the same in ointment form to the arm. In the course of a fortnight the nose had regained its normal size, and the granulations of the ulcerating surface were assuming a healthy and firm condition. At this time the patient showed signs of slight mercurial stomatitis. The application of the wash upon the nose was discontinued for a few days, and then used reduced to one grain to the ounce. At the end of six weeks the nose had completely healed over, leaving a nearly smooth surface. The tubercles upon the arm had completely vanished under the action of the ointment, which had been constantly applied morning and evening. The gland in the neck remained unchanged.

CASE V. A boy, aged thirteen, native of Boston. The disease had existed several years, and occupied

the whole chin, spreading down continuously upon the front neck to the level of the larynx. The central portion of this area was occupied by scar tissue, bounded in some places by active, crusting ulcers, in others by large boggy tubercles. The wash of bichloride of mercury was applied to the ulcerating surfaces, and the ointment to the tubercles. Within a fortnight the latter had shrivelled up in a surprising manner, and in a month they had entirely disappeared. The wash, on the other hand, seemed to produce but little impression upon the crusts and ulcers, and fearing to lose sight of the patient, and also partly for the purpose of exhibiting the process to my class, I treated this portion subsequently with the stick of nitrate of silver, under the repeated use of which the parts took on a healthy action.

CASE VI. A girl, aged fourteen, living in Boston. She exhibited on one arm a group of crusting tubercles of two years' duration. Upon the other arm there was a scar, the result of the same disease, which had not been in a state of activity for five years. Under the action of the bichloride wash and ointment, the tubercles were rapidly sinking down after a few week's use. She then ceased to attend my clinic.

CASE VII. A girl, eleven years old, a native of Massachusetts. There was upon the left cheek a firm, elevated patch, one by two inches in area, with sharply defined edges, slowly progressing through a course of six years. It was an example of the variety called by Vidal sclerosus lupus.<sup>3</sup> There were no well-defined tubercles, nor any ulceration or crust formation. The bichloride ointment, two grains to the ounce, was applied twice a day, but with very slow results. After its use for four months the whole patch had become depressed to one half its former elevation. The case is still under observation.

CASE VIII. A girl, thirteen years old, a native of Massachusetts. The patient had been under my treatment two years previous to the beginning of this series of experiments. She had when first seen numerous patches of sclerosus lupus scattered over arms and legs, varying in size from a dime to a silver dollar, and of irregular shape. The forehead was almost wholly occupied by the disease, as well as a large area of the skin below the chin. These patches were characterized by a nearly uniform, thickened, elevated condition, somewhat depressed in the centre, and by sharply defined, perpendicular edges. The central portions of the largest consisted of smooth cicatricial tissue, while the more recent parts were somewhat tubercular in appearance, especially at the edges, but the diseased tissue was very firm throughout, presenting very few inequalities of surface. There was scarcely any boggy tissue at any point, and the sharp stick of nitrate of silver had been made to enter it with very great difficulty. The case had been throughout an exceptionally intractable one under well known remedies. Two or three of the smaller patches had wholly disappeared finally after the repeated use of pyrogallie acid,  $\mathfrak{ss}$  to  $\mathfrak{ss}$ , but the larger part of them had resisted its action. A year ago I began to use upon several of the patches the wash and ointment of bichloride of mercury, and this treatment has been continued with numerous interruptions up to the present time. Under these applications, the elevated margins have very gradually sunk down nearly to the general level, and the dull, reddish-brown color has

<sup>3</sup>Annales de Derm. et Syph., 1884, p. 111.

grown pale, but the change has been exceedingly slow, and none of the patches can be said to have become wholly well again. During the use of the applications about the chin, there was a decided attack of stomatitis, so that they had to be suspended for a time and used with much caution subsequently. Very much remains to be accomplished in this case.

CASE IX. A girl of Irish descent, aged twenty. There was upon the left cheek a crusting patch, the size of an almond. The nostrils were thinned and nicked. On the tip of the nose and upper lip were several large, softening tubercles, partly covered with crusts. The disease had been in existence several years. To all of these lesions the bichloride of mercury ointment was applied. The change in their condition which followed was immediate and remarkable. Within three or four weeks, the excoriated surfaces had healed, and the tubercles, both hard and soft, had shrunk down to the general level of the skin. At the end of two months treatment was discontinued, as all appearances of the disease had vanished. Six months later, but a few weeks ago, a new tubercle developed upon the upper lip, at the edge of the nostril, which had broken down into an open ulcer before the patient presented herself again for treatment. This is the only instance of recurrence of the disease which has occurred after this treatment in a spot once apparently restored to a healthy condition.

The three following cases were seen in private practice.

CASE X. A young lady, twenty-one years old, a native of Massachusetts. Five years ago, she was under treatment for lupus of the larynx by Dr. F. I. Knight, and a report of the case may be found in the "Transactions of the Laryngological Association," 1881, page 13. At that time she had, according to her statement, a sore nose. In April, 1883, the nose became "sore" again; and when first seen by me in October following, there was a large, boggy tubercle upon the tip of the nose and the nostrils were nearly stopped by crusts. She was anemic and feeble. She had recently consulted Dr. Knight again, who found no disease of the larynx. An ointment of bichloride of mercury, one-half grain to the ounce, was first applied to the diseased parts, which after two weeks was raised to a grain to the ounce. In six weeks the nostrils had returned nearly to their natural condition at the edges, and the tip of the nose was much reduced in size, when it received a severe blow. Great inflammation followed, and the integument sloughed off, leaving an open ulcer as large as a dime. This slowly improved and had nearly healed under a continuation of the ointment, when a month later it again received a hard knock. This was succeeded by exuberant, fungoid granulation of the ulcerated surface, and great swelling of the whole organ. The application of the ointment was suspended, and the part was treated by a wash of tartrate of iron and potash, and a salve of boracic and carbolic acids as a dressing. In February the inflammation had so far subsided that the sulphurous acid treatment was begun, the tip of the nose being kept wet continuously through the day with a cloth dipped in a fifty per cent. aqueous solution of the same. This was used for seven weeks, but as it produced apparently no change in the lupus tissue, it was given up, and the part was thoroughly bored into with a crayon of nitrate of silver. This operation was repeated twice a week for two months, by which time

the part had completely healed. During the use of the bichloride, there was an attack of mercurial stomatitis, which led to the giving up of this method upon a part so near the mucous cavities.<sup>4</sup>

CASE XI. An American boy, aged five years. The patient was seen in January of this year. The disease began two years previously on the face and knee, and had made gradual and uninterrupted progress. He had an irregular, circular, elevated patch upon the right cheek, one by one-half inch in area, covered with a thick crust, which had been frequently removed by accident, to form again immediately. Upon the left knee there was a thickened and elevated lesion, of one-half the above size, soft and boggy in consistence, but still covered with epidermis. The general health had not deteriorated. An ointment of bichloride of mercury, one grain to the ounce, was directed to be applied to both patches twice a day. At the end of six weeks the crusts had ceased to form upon the cheek, and both patches had flattened down considerably and presented smooth surfaces. This treatment was continued until the middle of April, when an ointment—salicylic acid 3iss., vaseline ʒi, was substituted for the morning application of the mercurial salve. Two months later, the diseased portions of skin had returned to their natural level and presented a smooth, but still slightly discolored surface. When last seen, six months after the beginning of treatment, the appearances were as last described, and an application of a solution of salicylic acid in castor oil, four per cent., was directed to be made once a day to the parts, as the only and final treatment.

CASE XII. A girl, sixteen years old, native of Vermont. The disease began eight years ago upon the back of the left hand, and had gradually extended so as to effect nearly the whole arm. It began upon the face two years later. At her first visit in April, 1885, she presented the following appearances: The whole arm to within two inches of the axilla was greatly enlarged, partly by edema, pitting on pressure, mostly by a firm infiltration, a true elephantiasis hypertrophy. The hand was some three inches thick at the palm. The fingers were enormously bottled, as in advanced dactylitis, and offered a dense resistance to pressure. In the palm, on the back of the hand, and upon the forearm, were very large and highly-elevated, flattened cicatrices, some what corrugated upon the surface. Also firm prominences of large extent near the elbow, penetrating apparently below the general depth of the integument, not at all cicatricial in character. There were in addition scattered over the forearm numerous verrucous outgrowths of considerable extent and of a dark color, such as often occur secondarily in true elephantiasis of the extremities. Large areas of integument covering the fingers, back of the hand, and in the vicinity of the elbow, were in a state of open excoriation, not exhibiting much activity or deep ulceration, and partially covered with crusts. This same condition, it was stated, preceded the formation of the cicatricial growths. The central face was occupied by numerous, isolated tubercles, the size of a large pea, many of which were boggy and scaly upon the surface. The lower portion of the septum and the edges of the nostrils were in a state of superficial, open ulceration, and the latter were thinned and pinched. The glands on both sides of the neck were greatly enlarged, and there were marks of old necrosis, now

<sup>4</sup> At date of this publication the patient is apparently cured.

extinct, over the seat of one of them, upon the left lower neck. The larynx was examined by Dr. Langmaid, and found to be in a healthy state. The patient was anemic, and was reported to have had many attacks of erysipelas of the affected parts. She had had no systematic treatment.

According to the father's report, her sister had, between the ages of two and ten, "similar sores all over," some of which ulcerated through the neck, and allowed the fluids of the throat to escape. The bones of the fingers and jaws were affected. The disease proved fatal at the latter age. He stated also that his own brother and sister died of consumption, and that his mother had "scrofulous sores."

This case presented such striking examples of lupus lesions of all grades, and at the same time, such marked manifestations of "scrofulous" disease, the deep cutaneous infiltrations, the dactylitis, the condition of the glands, that I asked my colleagues in Boston, Drs. Wigglesworth, Greenough, and Tilden, to see the patient. It was the most remarkable case of association of the two conditions that I had ever seen.

An ointment of bichloride of mercury, gr. i to  $\mathfrak{z}$ i, was directed to be applied twice a day to the lesions upon the face, and a dressing of salicylic acid in castor oil, a four per cent. solution, to be worn constantly over the ulcerating surfaces upon the hand and arm. Ten days after the beginning of this treatment, an erysipelatos dermatitis of face and arm, with a decided disturbance of the general system ensued, so that the local remedies were suspended for two weeks. The attack was said by the patient to be identical with those which had occurred several times previously. Two months after the beginning of treatment she returned to Boston from her home. She had gained greatly in weight and strength. The tubercles upon the face had subsided nearly to the level of the skin, and the excoriations about the nostrils had disappeared. All the ulcerated areas upon the hand and arm had healed, and were covered with a nearly normal epidermis. There had been no change in the deeply infiltrated prominences, nor in the dactylitic condition of the fingers. It should be stated that the patient had been taking cod liver oil during this period, and that according to her statement, the disease was generally better in warm weather; but it seemed to me extremely improbable that such marked changes in the lesions could take place independently of the action of the local remedies.<sup>5</sup>

Although the number of cases here reported is small, and the larger part of the patients were imperfectly under observation and control, owing to the nature of an out-patient service, some positive conclusions may be drawn from their study, I think. The lesions of lupus in their early forms are certainly and rapidly acted upon by the direct application of corrosive sublimate. The tubercular manifestations, large and small, firm and soft, almost immediately begin to undergo a change under its influence. They shrivel and become paler in a single week after its application, and, in the majority of cases, shrink down to the general level of the skin in a month, or, in the case of large nodules, within two months. Rarely has it seemed necessary to prolong the treatment beyond this period.

The tissue involved returns to its natural condition apparently in all respects — consistence, color, and epidermal covering. In the more advanced stages of the disease, the ulcerating, crusting forms, I have not been so well satisfied with the action of the sublimate. It has been more uncertain, and always much slower in controlling the progress of the affection. In two cases I was obliged to give up its use, so inert did it appear to be. On the other hand, in some cases its action upon areas of open ulceration has been completely effective. Upon the least advanced or retrograded forms, the dull-red, more or less thickened, glazed or excoriating areas, sometimes extensive, its action is slow but seemingly satisfactory, the skin gradually recovering its natural appearances. In the rare sclerous forms of the disease, like all other remedies, its beneficial effect is extremely protracted, but still unmitigable. With regard to the durability of its action or the completeness of the cure which follows its use, it compares favorably, in my opinion, with other remedies. I do not speak with any certainty upon this point, for my experiments with it, at the farthest, run back but eighteen months, and relapses among out-patients often fail to be reported, but the cures have presented every appearance of being complete, so far as one can judge by the external condition of the skin, and I have seen but a single point of recurrence among all the cases. If its use be continued long and thoroughly enough, a point not yet sufficiently determined, I see no reason to doubt its absolute power over the parasitic nature of lupus. Concerning the best form of application, I am convinced that the sublimate ointment is much more effective in tubercular and all closed forms of lesion than the wash. It needs to be applied but twice a day to act continuously upon them, and the agent penetrates more deeply, I believe, in this form than in that of aqueous solution. Upon open, ulcerated, and crusted surfaces, I have chiefly used the latter, as it seems more appropriate to do so, although I have no satisfactory reason to offer for this opinion. Neither do I feel at all certain that I have employed the remedy in either form as strong or freely as I might have done safely and with more rapid results. The only objection to a more constant or a continuous application, or to a greater strength than one or two grains to the ounce of fat or water, is the possibility of the absorption of the drug to a dangerous degree. In the few accounts of its use in the disease which I have seen, it has been stated that no such results have followed; but in two or three of the cases under my observation, a decided stomatitis, salivation, red line about the edge of the gums, and swollen approximate glands, have ensued after the use of the above preparations for two or three weeks. This result never occurred, however, except when the disease affected the regions immediately bordering upon the mouth, and always rapidly subsided when they were omitted for a short time. In this region, so frequently the seat of the disease, such a danger is a decided objection to the use of mercurials, but with proper caution they may be effectively employed. I have seen no evidence of more general absorption or systematic poisoning, and I shall not hesitate to employ hereafter still more concentrated and continuous applications. I have had no experience with other forms of mercurial preparations, recently advised by Unna and others, nor do I see how they could be more effective than those of corrosive sublimate used in the above cases. I am desirous, however,

<sup>5</sup> Soon in September again, the patient's face presented no trace of the former tubercles, the skin of the arm had become entirely smooth, and the hand had resumed its natural condition so far that she could take lessons in piano playing. These later changes had followed the exclusive use of the application of salicylic acid.

of testing the effect of injecting its solution directly into the lupus lesions.

With the action of sulphurous acid in the disease, so strongly recommended by Mr. Hutchinson of London,<sup>6</sup> I have had but little experience, having employed it for a short time only in but three cases of the affection. Its powerful suffocative effects on inhalation when applied upon or about the lower face, its rapid volatilization when used as an evaporating lotion, and the speedy deterioration of its aqueous solution, are strong objections to its selection as a parasiticide in this affection. Possibly its solution in oil may be a more serviceable preparation. In any form its action would rank below that of bichloride of mercury in effectiveness, and its only superiority lies in its absolute safety when used over extensive areas.

Only recently I have been studying the action of salicylic acid upon the disease, in consequence of a notice of its employment by Marshall.<sup>7</sup> I have used it in solution in castor oil in three cases, in strength varying from two per cent. to four per cent. It dissolves readily when warmed with the oil. I have kept pieces of sheet lint saturated with the above solutions upon lesions of all grades and of considerable extent, and in every instance it has been well borne, forming indeed a bland and soothing dressing to the most active ulcerating surfaces in the affection. In one case only have I used it upon parts not previously treated by parasitocides, and in this (case xii) extensive areas of skin in a state of excoriation rapidly healed under the continuous dressings. Large groups of tubercles also were dwindling away under the same treatment, but I consider my experiments with it all too brief and limited to permit any conclusions to be drawn from them as to its value.<sup>8</sup> If its activity and certainty as a remedial agent shall be demonstrated, it will be of great service because of its non-irritative and absolutely harmless action upon the skin and general system, however extensively or continuously employed.

I present this very limited experience in the use of parasitocides in lupus and the meagre conclusions I have ventured to offer, to this association, in no sense as a satisfactory demonstration of their value, or as positively confirmatory of the bacillus nature of the disease; but so far as they go they have led me to form a decided opinion in favor of both, and I have little doubt that the continued study of the subject will lead to most valuable improvements in the therapeutics of the affection. The desire that my colleagues here may take an active and immediate interest in settling this important question must be a sufficient excuse for bringing to their notice so imperfect a contribution to the subject. Should farther experiments confirm the favorable impression produced by the recent trials of these remedies, what a revolution may they not be foretelling in our future power over, not merely other forms of tuberculosis, but syphilis and leprosy as well, by direct medication.

— It is stated by the daily papers that the anti-vaccination crank who has stirred up most of the resistance to vaccination in Chicago and Montreal, on being arrested, was found to have been vaccinated three times, the last time within a few weeks.

## SIMPLE CATARACT EXTRACTION.

BY HENRY W. WILLIAMS, A.M., M.D.,

Professor of Ophthalmology in Harvard University.

### II.

#### INDICATIONS FOR THE OPERATION.

THE last number of the *Annales d'Oculistique* contains a second able article on cataract extraction, by Dr. De Wecker, in which he considers the question of how much which is new, and how much which is worth preserving, has appeared during the twenty years of abandonment, by most ophthalmologists, of the former methods, and the substitution of the linear incision combined with iridectomy advocated by Von Gräfe. The capital points of difference were: first, the placing the incision in the sclera rather than in the transparent cornea; second, the reducing the height of the flap; third, the combination with iridectomy. The advocates of a linear scleral incision held that a better coaptation was obtained by giving to the wound a linear form, and that immediate cicatrization was promoted by the placing of the section in a more highly vascular tissue than the cornea. While, in Dr. de Wecker's judgment, we should utilize, as far as possible, every endeavor to obtain accurate coaptation and speedy healing of the wound, we can neither think of returning to the methods of the older operators, whose flap incision included half the periphery of the cornea, nor, on the other hand, should we extend the base of the flap into the non-transparent border of the cornea and too near to the iridal angle. At the time of the publication of his first paper on the subject, Dr. de Wecker was not aware that the method of simple extraction he so judiciously advocated, had already been for a long time preferred by eminent English operators, whose opinions he now cites as corroborating his own. Sir Wm. Bowman writes as follows: "I do not remember that I ever made a great point of the section for extraction of cataract being *exactly* one-third of the sclero-corneal margin, neither more nor less; but this certainly was about what it amounted to in a large number of cases. The extent of the incision *varied* according to one's conception of what the size and bulk, hardness or softness of the lens was likely to prove in the particular case; the principle being, to make the incision *quite large enough* but not *needlessly large*, to admit of the lens emerging without undue pressure and dragging, or the risk of having fragments broken off in its passage. I speak of extraction without iridectomy and without scoop. I generally preferred the incision to run in or near the corneal margin; but I was in the habit for many years of trying various methods, from extreme marginal to more or less far intra-corneal ones."

Mr. Critchett, in cases where he thought there was little risk of suppurative, performed Lebrun's median flap operation; the incision being wholly within the limits of the cornea, and the apex of the flap being nearly at the level of the upper margin of the pupil in a state of moderate dilatation.

Dr. de Wecker admits, with Bowman, that a wise eclecticism may allow of a somewhat larger flap than that which he advocates, comprising exactly the upper third of the cornea, in cases where the size or density of the lens may require more room for its easy emergence.

The facility with which the iris became nipped between the edges of the peripheral sections, had led their advocates to perform large excisions of this men-

<sup>6</sup> Medical Times and Gazette, April 26, 1881.

<sup>7</sup> British Medical Journal, June 25, 1881.

<sup>8</sup> See foot note to page 413.

braue. But pathological anatomical researches have shown that the supposed advantages of this excision were illusory, and that, in nearly all the eyes dissected after a peripheral extraction combined with iridectomy, adhesions and strangulations were found.

There is no comparing such adhesions of peripheral portions of the iris, in a wound close to its ciliary insertion; with adhesions of the iris, near its sphincter, to a corneal cicatrix.

The first of these conditions involves pain and extreme sensitiveness of the ciliary region, often going on to destructive irido-cyclitis; whilst prolapsus and adhesions of the sphincter or of neighboring parts of the iris in the corneal wound, are the source of no trouble.

The results of good operators with Gräfe's operation show a diminished proportion of suppurations as compared with the ancient flap methods, but they also show a more tedious and painful curative process, and the frequent occurrence of destructive irido-cyclitis after months of suffering, with perhaps the subsequent loss of the other eye by migratory inflammation—accidents which were quite unknown to the older operators.

In discussing the possible merits of combinations of simple extractions with iridectomy, Dr. de Wecker insists strongly on the evils attending the excision of even small portions of the iris, as giving opportunity for capsular adhesions; and calls attention to the importance of preserving the integrity of the iris so that the physiological action of its sphincter shall be unimpaired, in order that by its traction upon the peripheral portion the iridal angle shall be kept free; instead of allowing this angle to be effaced by adhesions of the incised edges of the iris to the inner surface of the wound; which disturb the system of filtration through the lymphatic spaces of the eye and perhaps create a cicatrix favorable to the migration of germs from without.

Healthy conditions at the iridal angle are a potent safeguard against subsequent accidents.

In Dr. de Wecker's opinion it is also proven that excisions of the iris, far from being a help, are a disadvantage as regards the healing of the wounds after cataract extraction, and that the keeping of the sphincter intact gives greater security for perfect cicatrization. In his judgment, the conditions in which iridectomy may be allowed are limited to those cases of cataract in subjects less than sixty years of age, and in diabetic patients, where viscous portions of cortical lenticular substance remain adherent within the capsule and are only to be dislodged by prolonged friction. With these he would include some cases of unripe cataract; although such immature cataracts are usually of firm consistence and are readily expelled, even when still so transparent as to allow of one-tenth of visual acuteness; provided the corneal incision has been made sufficiently large.

Iridectomy may also be done if an increased tension of the eyeball, or a persistent disposition to prolapse of the iris through the wound, causes suspicion of glaucomatous tendencies; or if much indolence of a patient may threaten to give rise to secondary prolapsus; but it should be done in these cases only at the last period of the operation.

The advantages obtained in cataract operations by the use of cocaine are inestimable. Almost instantaneous abolition of sensibility of the eye being thus obtained,

every part of the operation may be deliberately done, without disturbing the patient's tranquility, and without rendering him unconscious; and with much aid, in many cases, on his part, in turning and retaining the eyeball in the desired positions.

Less use of subsidiary instruments is also made possible, and the inconveniences and occasional dangers resulting from the use of anæsthetics as well as the risks involved in operating where these were not employed, are wholly and most agreeably avoided.

# CASE OF EARLY SYPHILITIC CEPHALALGIA FOLLOWED BY APHASIA, PARAPLEGIA AND DEATH, WITH AN ACCOUNT OF THE AUTOPSY.<sup>1</sup>

BY LE GRAND N. DENNLOW, M.D.,  
Professor of Diseases of the Skin and Syphilis in the St. Paul Medical College.

ON April 29, 1885, I was called to see Mr. B. in consultation with Dr. Ritchie. Dr. Ritchie gave me the following history:

About two months ago the patient was first seen. He was then suffering from a very severe headache, which was much worse at night. Had alopecia and a papular eruption more pronounced about the face and scalp. He acknowledged having had a sore on the penis late last year. The doctor prescribed potassium iodide in increasing doses up to a half ounce daily, also croton chloral. At the end of two weeks the patient was free from pain, and, contrary to the doctor's advice, left for his home in the country. At the end of another two weeks, or one month after he was first seen, he wrote that the pain in the head had returned, and that he had not been taking any medicine for several days. Dr. Ritchie then ordered sixty-grain doses of the iodide three times daily, but by mistake, the patient was given that dose every two hours, with the result of upsetting his stomach, but not relieving the pain. He was then advised to come back to the city, which he did after two weeks delay.

At this time I saw him. He was then unable to speak, and was unable to comprehend questions, his hair was falling still, and he was paraplegic. The eruption had not yet disappeared. He was at once ordered one-tenth grain doses of calomel, hourly, and thirty-grain doses of iodide every two hours in three-fourths of a goblet of milk; he, however, sank very rapidly, and died comatose, May 3d, four days after I saw him, and two months after first coming under observation.

Autopsy at midnight of the same day, twelve hours after death. Rigor mortis well marked. Body fairly well nourished. No oedema. No external signs of injury. Abdominal and thoracic cavities normal. On removing the calvarium, the dura-mater along the superior longitudinal sinus was found to be thickened and adherent to the pia mater. On the external surface of the pia there were seen numerous small gummata or cheesy-like masses about the size of millet seeds; these were situated mostly along the right border of the superior longitudinal sinus extending down to the upper extremity of the fissure of Sylvius. Both the dura and the pia mater showed signs of simple acute inflammatory changes in the regions covered by those masses. The ventricles

<sup>1</sup> Read before the American Dermatological Society, Aug. 28, 1885.

and interior of the brain showed no pathological changes.

This is, I believe, the first autopsy ever reported, in this country at least, subsequent to the cephalalgia of early syphilis.

## Reports of Societies.

### BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

E. M. BUCKINGHAM, M. D., SECRETARY.

OCTOBER 12, 1885, the President, Dr. F. W. DRAPEK, in the Chair.

#### TWO CASES OF CALCULUS. RETENTION OF THE CATHETER.

DR. A. T. CABOT showed the specimens from two cases of stone in the bladder, operated upon by him during the past week.

CASE 1. A young man of twenty, from the Provinces, whose symptoms dated from last April. At that time he began to have pain during and after the act of micturition, the urine becoming thick, with a purulent sediment, and occasionally containing some blood. He had been sounded at his home and no stone had been detected. He entered the Mass. General Hospital October 9th, and a sound passed on that day touched a stone. October 10th, Dr. Cabot performed lithotomy under ether. The stone when grasped showed a diameter of about one inch, and it broke up easily. When the lithotrite was withdrawn, it stuck somewhat in the prostate and came up so tightly through the urethra as to make it evident that some foreign body was caught between the blades. There was a good deal of resistance when the meatus was reached, and this had to be slit up considerably before the jaws of the lithotrite and their contents could pass through. It was then seen that several fragments of a leather shoe-string were in the grasp of the instrument.

The stone, which had been thoroughly crushed, was pumped out, and among the debris were many small pieces of the string. The stone weighed one hundred and thirteen grains and the string was about eight inches long. The patient confessed on the following morning to having lost the string in the bladder on the 25th day of last April. His recovery from the operation has been satisfactory, his temperature not having been above 99° F. since the following day.

CASE II. The patient, a stout man of fifty-seven, entered the Mass. General Hospital October 7th, 1885, with the following history. Seven years ago he was seized with "kidney colic," and this recurred again four years ago. At neither of these times did he pass any calculus of appreciable size; and as each of these attacks came and went gradually, it seems probable that they were caused by the passage of fine sand rather than by a single stone. He has had no urinary symptoms since that time until ten days ago, when he was suddenly seized with pain, referred to the root of the penis and accompanied by obstruction to the passage of water. This continued until three days ago, when the stoppage became almost complete. On the day of entrance, Dr. Van Slyck, of Brookline, who was called, passed a metallic instrument and touched a stone impacted in the urethra. He was etherized, and Dr. Cabot with a sound pushed the calculus, which

was in the prostatic urethra, back into the bladder. On attempting to pass a tube, the urethra was found to be a very narrow one, barely admitting a 25 F., even after the meatus was freely slit. The calculus would not pass through the tube of this size and it was accordingly crushed and pumped out. Its weight was only ten grains. After the operation the patient continued to have considerable difficulty in passing water, and his temperature went up each evening to about 103° F., falling in the morning to normal. On the third day, the difficulty in micturition remaining unabated, an English webbing catheter was introduced and tied in. The temperature at once fell nearly to normal and remained there.

This case seemed to illustrate very well the advantage which is occasionally to be derived from constant and efficient drainage of the bladder through a catheter. It seemed probable that the obstruction was due to inflammatory swelling in the prostatic urethra, consequent upon the irritation of the calculus. The drainage of the bladder gave the parts rest and the chance to recover themselves.

DR. GEORGE W. GAY said that his experience had taught him that while leaving in the catheter often does more harm than good, yet that there were cases in which it results in a better condition with less irritation than frequently passing it. He cannot indicate the cases exactly, but knows that both classes exist, and thinks that there is a prejudice on the subject which is not well founded.

DR. F. S. WATSON said that Dr. Cabot's case well illustrates the advantage to be derived in certain cases from the practice of tying in a catheter after operations on the urethra or bladder. There should be no hard and fast routine rule of employing this method of treatment or of omitting it. He had advocated in general the omission of a catheter *à demeure*, after internal urethrotomy for anterior strictures. There, however, is generally no question (if the operation has been well and thoroughly performed), of imperfect drainage from, or of complete power of emptying the bladder afterward from temporary inflammatory swelling of the prostatic mucous membrane, as was pointed out to be the condition in the case of stone just reported by Dr. Cabot. Where such an obstruction does exist, the use of the catheter is, no doubt, of value, for the reason that it secures good drainage from a bladder that cannot drain itself.

This, it seems to him, is a distinction which should be dwelt upon, as it gives a rational ground upon which to base the use or omission of the catheter in such cases. Where no such indication is present, the catheter may be omitted with advantage, as it itself is likely to prove a source of mechanical irritation and be productive only of harm, especially when employed, as it so frequently is, without especial precautions as regards cleanliness.

#### SARCOMA AND OSTEO-SARCOMA.

DR. M. H. RICHARDSON showed a tumor removed by him from the internal femoral region of a man of thirty. Its origin was from the fibrous sheath of Hunter's canal and from the fibres of the adductor magnus, and it rested upon the femoral artery. The clinical diagnosis had been obscure, owing to the hardness of the tumor and its rate of growth, twelve years. The microscopic diagnosis, made by Dr. Whitney, was sarcoma with a shell of true bone. Removal had

involved some difficult dissection. So far there has been a good recovery.

To a question by Dr. Gay, Dr. Richardson answered that the tumor was separated from the femur by about an inch.

DR. GEORGE W. GAY said that it is rare for a sarcoma of twelve years to be no larger, yet that the difference in growth is surprising, and he illustrated this by the following cases:—

A sarcoma had risen from a sprained foot and this led to amputation of the leg five years ago. Two years later the disease reappeared, where the shoulder-strap of the artificial leg crosses the spine of the scapula, and in two years it had increased to an enormous growth which wore the lady out, she having been sick nine years in all. Another case having origin behind the axilla, after being twice removed, caused death in nine months from the beginning.

As a rule osteo-sarcomas were of rapid growth. Probably gentlemen present remembered Dr. Thorndike's amputation at the hip joint for a tumor of three years' standing, which, with the limb, weighed sixty pounds.

Dr. Gay also spoke of two cases high up on the humerus which being removed in about a year, did not heal, but necessitated amputation at the shoulder joint. These looked like the tumor shown by Dr. Richardson. He referred to a woman of twenty, confined with her second child six months ago, and remaining in bed five weeks. Six weeks ago a tumor was discovered attached to the symphysis pubis, and it is already five inches by six, and can be reached by a finger in the vagina as if attached to the symphysis by a hinge. The question of removal is under consideration.

On the other hand, cases will grow very slowly for years and then suddenly increase. A middle-aged woman has had a tumor of the parotid for eighteen years, and six months ago it was no larger than a walnut, but has since that time grown to the size of a goose egg, and is soft, bright red, and apparently a sarcoma. Dr. Richardson's case was, the speaker understood, of uniformly slow growth.

Dr. Gay believes in taking out sarcoma, even if it is fast in growth, and if it has to be repeated. Even if life is not prolonged yet it is made more comfortable, and the patient is kept out of the hands of quacks with their abuses. In a case recently under his care, he hesitated at a fifth operation; only because he believed that the disease had invaded the lung as well as accessible parts.

DR. CABOT said that Dr. Richardson's case had grown rapidly of late.

DR. WM. P. BOLLES read a paper entitled

#### ANTISEPTIC SURGERY AT THE BOSTON CITY HOSPITAL.

which was, as was stated by the reader, a report not of all the work done at the hospital, but of his own work merely, and during his recent term of service of about four and a half months only; and it did not include cases in which antiseptic surgery was not attempted, such as operations about the nose, mouth, urethra, rectum, and perineum, where the mechanical difficulties are great, and it did not, of course, include cases of injury in which the skin remains unbroken; but it did contain a report of every case in the service in which antiseptic surgery had been attempted; including all cuts and wounds other than those above excepted and most abscesses. These reports, which

were made with a certain amount of detail were not intended to advance any particular theory of disease, but to allow comparison with cases in which antiseptics is not attempted. They included cases in which the reader knew that complete asepsis had not been reached.

The methods involved a routine, in order to avoid the accidents otherwise sure to creep into a large service, such as the use of non-aseptic ligatures in a carefully cleansed wound, the use of instruments that may have been handled by unwashed hands after removal from a carbolic acid tray, and the like; accidents sufficient to make useless the precautions taken. The particular method used was that used in Vienna, and was chosen partly because of its formality, and partly because it is probably over sufficient. In outline it is as follows: "The patient who has had a complete bath and other cleansing within twenty-four hours if the operation is a great one, is first washed about the part with soap and water and scrubbed with a flesh brush; second, shaved; third, wet with two and a half per cent. of carbolic acid. The surgeon and all attendants who touch the affected part, first wash with soap and water, scrub with flesh brush, clean their nails; second, wet with the carbolic solution. If they have been dressing suppurating wounds, making vaginal or rectal examinations, or any such work; which is to be avoided if possible, before an operation; after washing, third, wash again in a purple solution of potassium permanganate, and rinse in a solution of oxalic acid, before wetting with carbolic acid. All wear clean washed coats. The instruments are laid in a five per cent. solution of carbolic. They must be scrupulously clean and bright. The silk for sutures and ligatures and the sponges are kept in five per cent. carbolic.

"The operation is done under a moderately continuous flow of two and a half per cent. of carbolic. Hemorrhage is carefully stopped, ligatures plentifully used and all ends cut, the wound, if possible, brought thoroughly together, drained if deep, and packed if hollow. Deep and muscular sutures are frequently used. The packings are made of strips of cleansed cheese-cloth, thoroughly dusted with fine iodoform, and parts of the same material are laid immediately over the wound. Cleansed gauze is laid over this and then common gauze and cotton and bandages. There are variations, but this is the essential plan."

No fresh cut has failed of immediate union to any important extent except where prevented by mechanical reasons. There has been almost no suppurating in fresh operations. There has been little surgical fever and no erysipelas or pyæmia. There has been little after-suppurating, and there has been no case of iodoform or carbolic poisoning. There has been a small extra diet and stimulant list.

DR. J. COLLINS WARREN said that antiseptic surgery resembles religion in that it is something that all strive for, and that such a paper will lead to renewed efforts.

While antiseptic treatment has made a great difference in the healing of wounds, yet it is not always successful, and fresh enthusiasm is needed to keep us up to the mark. To get the best results in hospital service, the co-operation of every one is needed, from superintendent to scrub-woman, and here lies a difficulty in our organization; in that with terms of short service, the surgeon finds his assistants of various grades untrained to his particular method, but to one

which, although perhaps as good, he does not prefer. Success lies in attention to detail; but though during his term, the surgeon trains his assistants, yet on resuming duty in the following year he finds the personnel changed and the work is to be done over.

Dr. Warren spoke highly of the use of sterilized cotton as a dressing which has been used at the Massachusetts General Hospital since last spring. It is sterilized by heat in tightly closed baskets, and can be prepared on the day of operation, although a longer exposure to a somewhat lower temperature is thought preferable. The physical properties of cotton so treated are desirable, it being moderately absorbent and soft and readily adapted to place. The idea of its use was taken from the cotton plugs of culture tubes.

Dr. E. H. BRADFORD said that having served with Dr. Bolles, then having succeeded him, he has both seen the carefulness of his work, and inherited the benefits of his system; and while he could testify to the difficulty of getting assistants properly trained, he did not think it so great as one would suppose from Dr. Warren's remarks. A needless amount of mystery has been thrown about the matter of antiseptic dressings, which is really but a matter of common sense. The methods of Lister are to-day antiquated, depending as they did upon the idea that the air is full of germs against which it is necessary to seal a wound. The more practical idea is that of the Germans. It is to keep the wound clean, not to guard it against a miasm. Irrigation is more practical than spray, and spray is useless if it is to be accompanied by dirty threads. The use of spray by men who did not understand what it can accomplish has done harm. The essentials are cleanliness, drainage and absorption of discharges. He prefers dressings of clean cheesecloth wet with corrosive sublimate and partly dry. Then a half-inch of dry cotton treated with boracic acid and then bandages, over all he would place a layer of moss, which is not however collected here. Iodoform is useful. He closed his remarks by hoping that Dr. Warren would adhere to the religion of antiseptic surgery.

Dr. M. H. RICHARDSON said that he could testify to the good results from the use of sterilized cotton for this purpose.

Dr. CABOT criticized Dr. Bradford's remarks as giving the impression that Listerism is antiquated. Listerism, pure and simple, is keeping from the wound something that is outside of it, and which will make the wound do badly. Beyond this all is mere detail. The Lister gauze is still an excellent absorbent, and the spray acts mostly as an irrigator. One important element of an antiseptic dressing is firm, even pressure which prevents the flaps filling with blood, as they do if loosely put together.

Dr. GAY said that antiseptic surgery needs no argument, and it need not be intricate. If one keeps in his office an insufflator charged with iodoform, some absorbent cheesecloth or cotton, and either carbolic acid or corrosive sublimate, he has all the apparatus necessary. A secret of success lies in bandaging, as Dr. Cabot says, and having got the wound clean, to keep it clean, and to avoid disturbing it by renewed dressings, thereby breaking fresh adhesions, a practice by which formerly much harm was done.

Dr. BRADFORD remarked that he had not said that Listerism in its broadest sense was antiquated; that

Listerism consisted in keeping out a special ferment, that is antiquated. Pasteur says that we prevent contagion, not that we prevent miasm.

#### NEW YORK STATE MEDICAL ASSOCIATION. FIFTH DISTRICT BRANCH.

First annual meeting held in Brooklyn, October 13th, 1885.

##### MORNING SESSION.

The meeting was called to order by the president, DR. JOSEPH C. HUTCHINSON of Brooklyn, who made a short address. DR. ROBERT NEWMAN of New York, read the first paper, which was on

##### THE PROGRESS OF ELECTROLYSIS IN SURGERY.

It was a continuation of his former paper, read before the American Medical Association in 1883, on electrolysis in surgery, with tabular statistics of one hundred cases of urethral stricture, successfully treated by this method, and its object was to show what had been accomplished in this field during the past two years. The only absolutely new application of electrolysis which had been made appeared to be the adoption of the method in the treatment of hernia and hemorrhoids, by Dr. Craft, of Cleveland. The radical cure of hernia, by means of electrolysis, was novel and original, and Dr. Craft's results had not been published, the information concerning them having been received by Dr. Newman through private correspondence. In a letter to him, dated Cleveland, May 7, 1885, Dr. Craft stated that he had been using electrolysis in two diseases which were not referred to in this connection in his paper, namely, hernia and hemorrhoids. He had applied a positive needle electrode, properly insulated, except at the point, subcutaneously between the external and internal rings, and allowed a sufficient galvanic current to pass between the poles, being careful not to injure the cord, and to keep the needle external to the peritoneum. This resulted in a cicatricial sealing up of the inguinal canal, and in many cases seemingly permanently.

In a second letter Dr. Craft described the method more fully, as follows: In operating, the hernia should be reduced first, and the sac carried up with it if possible. Invaginate the index finger in the scrotum, keeping the cord and sac, if it remain in the ring, well pressed to one side, and held there beneath the invaginated finger, which should be pushed into or through the external ring, if possible. Then with a sharp-pointed bistoury prick through the skin over the external ring. Through this puncture push a blunt-pointed needle electrode, insulated to within a quarter of an inch of the end, carrying it well up between the rings, by the side of the invaginated finger, which holds the cord and vessels from contact with the electrode. Connect the current of about ten cells of a good galvanic battery continuing the current for about six to ten minutes, according to the sensibilities of the patient, changing the point of the electrode from one side of the finger to the other, always keeping as clear of the cord as possible, and directing the current from the cord. The other electrode can be held by the patient in the hand of the side operated upon, or elsewhere as is desirable. You ask why I use the positive pole instead of the negative. For the reason that the posi-

tive is not as painful as the negative, and, being the acid pole, I conceived that it would excite sufficient irritation and inflammation, and at the same time coagulate the blood in the small vessels, thereby creating a harder cicatricial or adhesive inflammation than the negative or alkaline pole. I think the negative pole softens tissues and will cause absorption of already formed cicatricial tissues; but in hernia, we want a hard adhesive inflammation excited, thereby effectually sealing up the rings and canal. The more inflammation excited, (so that it does not injure the cord, and vessels, and falls short of suppuration), the more radical will be the effect. There is no foreign matter deposited, as is the case in subcutaneous injections, to form a nucleus for suppuration. The patient should lie in bed for at least two weeks, and then use a well-fitting truss for some time, until the parts become strong and firm.

Having described Dr. Craft's method of treating hemorrhoids by means of electrolysis, Dr. Newman went on to speak of the successful results of its application in port wine marks, epilation, and uterine tumors. In regard to the practicability of the method in the treatment of the latter, he said there was a great diversity of opinion in the profession, and this was no doubt due to the fact that some such growths were amenable to electrolysis while others were not. A variety of circumstances also always had to be taken into consideration, such as the general state of the patient, and the great difference among operators. Whoever knew the power of electrolysis would have confidence that uterine fibroids and other tumors could be cured by it. In this connection he referred to over one hundred successful cases treated by Dr. Freeman, of Brooklyn, Dr. Everett, of Clyde, Ohio, and Drs. Menière and Apostolic, of Paris. In conclusion, he spoke of the application of electrolysis to strictures of the catheter tube, and of the esophagus.

In the discussion which followed the reading of the paper, Dr. Rochester, of Brooklyn, said that he believed electrolysis to be an extremely uncertain method of treating uterine fibroids, and mentioned some cases in which it had been tried under his personal observation.

Dr. NEWMAN said that electrolysis acted in different ways, according to the way in which it was used. Weak currents would cause absorption, while strong ones would destroy. His own experience had been different from that of Dr. Craft as regards the comparative painfulness of the action of the two poles. Contrary to him, he had found that the positive pole caused more pain, acting, as it did, as an acid caustic, while the negative acted as an alkaline caustic.

Dr. GOVAN, of Stony Point, Rockland County, read the report of a

#### CASE OF DEPRESSED FRACTURE OF THE SKULL FROM RAILROAD ACCIDENT.

The peculiarity of the case was that the depressed bone became raised spontaneously, and the patient, who had remained in a state of unconsciousness for several days, then began to recover.

Dr. GOVAN also read the report of a

#### CASE OF POISONING BY ANILINE OIL.

The accident was caused by the breaking of a carboy of aniline oil which the patient was engaged in carrying; so that his clothes became saturated with it, and he freely inhaled the vapors arising from it. He re-

mained in a stupor for a number of hours, and there was complete anaesthesia of the entire cutaneous surface. On the third day also, there was some hemorrhage from the bladder, and this continued for two days, when it was controlled by the use of tannic acid and *uva ursi*.

The president thought that the cutaneous anaesthesia noted in this case was of the same character as that produced by carbolic acid. It was probably not known as generally in the profession as it deserved to be that carbolic acid was one of the best possible applications that could be made in cases of burns, as suggested by Dr. Squibb several years ago. He related some cases showing its efficacy in this regard.

Dr. GOVAN said that since he had met with the case that he had reported he had used aniline oil for the purpose of producing local anaesthesia when laying open felonous and performing other minor operations. There was absolutely no pain, even in cutting down to the bone, when the finger had first been dipped for a short time in the oil.

Dr. E. H. SQUIBB, of Brooklyn, remarked that the hemorrhage from the bladder in Dr. Govan's case seemed to indicate that the aniline oil was largely contaminated with carbolic acid or other by-products of the coal tar series, different members of which were given off at different temperatures. It would be interesting to note whether the peculiar effects produced in this case would result from poisoning by a specimen of perfectly pure aniline oil.

Dr. WM. H. PAXCOAST, of Philadelphia, who was present by special invitation, said that generally when local anaesthesia was resorted to, the patient suffered more or less pain from the operation, and he was gratified to learn from Dr. Govan that when aniline oil had been used for this purpose there was absolutely no pain during the cutting of a felon, for instance.

In his own practice he was in the habit of combining Bonwill's method of inducing anaesthesia by means of rapid inspiration with the inhalation of a few whiffs of chloroform. Bonwill's method was not sufficient of itself, and he could not but feel that the efficacy of this procedure was largely due to its moral effect upon the patient. One great advantage of the use of general anaesthetics over local was, that they not only prevented all pain, but also removed the dread of suffering.

#### AFTERNOON SESSION.

Dr. A. FLINT, of New York, read a paper on the subject

#### SUGGESTIONS IN REGARD TO THE CAUSATION AND TREATMENT OF ACUTE CORYZA.

In this affection the nostrils are first affected, and the trouble might go no further; but, as a rule, it progressed to other neighboring parts, with the result of producing pharyngitis, laryngitis, or bronchitis. The use of the term catarrh, which was often employed both by the profession and the laity in speaking of coryza and the other affections named, was an antiquated error, which should long ago have been given up. The word cold, so generally in use, implied a change of conditions in which the temperature of the atmosphere was necessarily concerned; but it was his aim to show that it was highly probable that coryza did not result from any agency connected with the atmosphere, but from a specific micro-organism.

In the first place, it was demonstrable that cold had

very little to do with the causation of coryza. Among those who were especially exposed to sudden successions of high and low temperature it was rare; and the same was true as regards those who are exposed continuously for a long time to cold.

In a large proportion of cases the affection could not be referred to any special exposure whatever, and experience thus furnished very little support for the ordinarily accepted view. As was well known, coryza often operated in a more or less general manner, more than one person being affected at a time; and this would seem to indicate a specific cause. This was everywhere recognized as regards influenza, and as the latter was only a more intense manifestation of the same disorder, it was logical to infer that the same held good in regard to ordinary colds. One fact which afforded support to the parasitic hypothesis was, that in a cold the various parts of the respiratory tract was affected, not simultaneously, but successively; which would be satisfactorily explained by the time which was required of the micro-organisms to multiply into colonies after obtaining a lodgment on the mucous membrane.

These, then, were some of the rational grounds for the probable parasitic origin of acute coryza. To establish the point with certainty it would be requisite to demonstrate that a specific micro-organism was always present in the affection, that it was never found in any other condition, and that it could be successfully cultivated outside of the body. It was highly desirable, therefore, that some of our competent microscopists should undertake the investigation of this subject in a thoroughly scientific manner.

#### TREATMENT.

If the existence of the parasite which he had assumed was a reality, Dr. Flint said, the destruction of the latter by some suitable agents would naturally cut short an attack of coryza at once. He had consulted four of the latest works in which the subject of coryza was treated, by authors of established reputation, namely: Cohen, Ingals, Robinson and Bosworth, and only one of the writers referred to the probable existence of a micro-organism capable of producing the irritation of the nasal mucous membrane met with in a "cold in the head." This was Cohen, and he spoke of the parasite exclusively in connection with the subject of influenza; not referring to it at all as the possible cause of ordinary coryza. All these writers, however, favorably mentioned the use of topical remedies.

Dr. Flint then referred to the Brandt treatment by means of carbolic acid and ammonia inhaled from a sponge; but stated that its efficacy had not been attributed to the antiparasitic action of the remedies employed. He did not claim any originality, he said, in calling attention to the probable parasitic origin of acute coryza. Many years ago, Dr. J. K. Mitchell, of Philadelphia, had intimated that such was the fact in regard to this and other similar affections, and more recently Sir Henry Holland, of London, and Mütter, of Vienna, had also entertained similar views. The topical treatment so generally recommended, while not ostensibly employed for its parasitic action, would, he believed, be found in reality to derive its efficacy from its energy in this direction. Thus, among the agents so used were permanganate of potassium, salicylate of sodium, the vapor of turpentine, and quinine and camphor in combination.

Finally, having spoken of Hehnholz's quinine treat-

ment of hay fever, Dr. Flint said that if a parasiticide were to be discovered which was constantly successful in cases of acute coryza, it would afford strong rational grounds for the correctness of the doctrine suggested.

The paper was discussed by the President, Dr. Wyckoff, of Brooklyn, Dr. Brush, of Mount Vernon, Worcester County; Dr. Pancoast, of Philadelphia, and Dr. P. Brynberg Porter, of New York.

DR. WILLIAM MCCOLLOM, of Brooklyn, read the report of a rare case,

#### UNIFORM CIRRHOSIS OF BOTH LUNGS.

The patient had the history of specific disease in early life. A few months since, he began to suffer from emotional excitability and from occasional paroxysms of dyspnea. These asthmatic seizures were liable to be brought on by unusual emotion or exercise, and as time went on, they increased in frequency. A careful physical examination of the chest, however, did not detect any appreciable cardiac or pulmonary trouble. Afterwards, Dr. Sherwell, of Brooklyn, examined the larynx, but found no evidence whatever of any disease. He expressed the opinion that there was probably an aneurism of the arch of the aorta. Still later, the patient was examined by Prof. Austin Flint, who found only some subcrepitant râles. He believed that there was pulmonary edema present, but could not say from what cause it proceeded. In the meanwhile, the dyspnea was steadily progressive, and on the 24th of September last the patient took to bed. On the 25th, he was examined by Dr. James R. Leaning, of New York, who thought that there were extensive pleuritic adhesions present, both old and new; an opinion in which he was confirmed by subsequent examinations.

The patient died October 5th, and the autopsy showed that the kidneys were entirely free from disease, and that the liver, with the exception of being possibly a little fatty, was also normal. The pericardium contained two ounces of fluid, and the right ventricle was found to be moderately dilated. Otherwise, the heart was perfectly healthy. The thoracic aorta was also free from disease. The lungs were of a dark gray or brown color, and floated in water. The parenchymatous structure of both lungs was very hard and dense, and creaked under the knife. There was no evidence of acute pneumonia, and no cavities were found. The only adhesions discovered were two slight ones at the top of the right lung, and they were evidently very old. (Specimens of the lungs were exhibited.)

DR. FLINT said that he remembered the case perfectly well, having made some notes on it himself, and he was very glad to know the results of the autopsy. When he made the examination of the patient's chest, he could discover nothing but the presence of a moist râle on both sides. He then felt quite sure that there must be disease of the kidneys, and requested specimens of the urine. When, however, the examination of the latter gave a negative result, he felt at a loss in regard to the case, and asked to be allowed to see the patient again. The condition of the lungs found after death completely explained the progressive dyspnea, and at the same time, it served to illustrate the inadequacy of physical signs under certain circumstances.

The remarkable point about this case was the equal development of the pulmonary cirrhosis on the two sides. Almost invariably the condition was much more

marked in one lung than in the other, so that the difference between the two sides of the chest was very apparent. The existence of moist râles in connection with a normal condition of the heart seemed to him to indicate kidney disease, and he was therefore surprised to find that the urine gave no evidence of this. On the whole, therefore, he considered it a very interesting case, and the specimens that had been presented he believed were unique. He thought it worth while, in this connection, to call attention to the mechanism of subcrepitant râles. One observer, as the history showed, had referred these râles in the present case to the presence of pleuritic adhesions. From the result of the autopsy, however, it was partly evident that here the subcrepitant râles were produced in the smaller bronchial tubes, and not in the pleura.

DR. PANCOAST having been called upon by the Chair, made an address on

#### SOME POINTS IN SURGICAL PRACTICE AND SURGICAL ANATOMY.

The first topic upon which he spoke was a system of surgical treatment which had proved of great value in his hands, to which he had given the name of "the antiphlogistic touch of the therapeutic knife." If he saw a patient early enough, this enabled him to say with almost absolute certainty that there would be no abscess. Having exhibited the little knives which he had devised, he stated they were so shaped as to puncture without cutting, and that they left no scar. By means of one of these, the part was punctured in numerous places, and the dead blood left out. The method was applicable to tumors of almost any sort, as it afforded the best possible deep-seated blood-letting of the part. The moment a bulb, or other gathering, became hard and refused to yield to the action of local applications, he freely punctured it with his little knife, and occasionally he found that there would be a drop of pus on the point. By this method he had even cured some cases of goitre, both cystic and fibroid, or at least, rendered the growth so small that it gave no further trouble. He also gave internal remedies, however, such as Donovan's solution and iodide of potassium, with the addition of cinchona or whiskey, if the patient's condition seemed to demand it.

The next point was one in connection with the surgical anatomy of the face, namely, the special value of the malar bone, which was often overlooked by surgeons. It was one of the hardest bones in the whole skull, and it therefore served as a great protection; while if it could be saved, much deformity of the face might be prevented. In excision of the superior maxilla, consequently, he always made it a point to have this bone in position; and he then proceeded to describe the operation which he had devised for this purpose. This consisted in a double curved incision, and, after turning back the soft parts, in inserting a chain saw through the sphenomaxillary fissure, and so cutting through the articulation of the superior maxillary with the malar bone. The value of the malar bone in protecting the brain was well illustrated in the case of a boy, from whose face he extracted the breech-pin of a gun which had been imbedded in it, without any one's knowledge, for eleven months. The gun had exploded in his hands, knocking him senseless; and the breech-pin had buried itself so completely in the tissues that it was not discovered by the physician who attended him. Strange as this case seemed, it was not unique;

similar ones having been reported by the late Dr. J. R. Barton, and by a surgeon to one of the ophthalmic hospitals.

Dr. Pancoast next made a report of his treatment of varicocoe, which he said he had now successfully practiced in over four hundred cases. It was very simple, and therefore in marked contrast to that so much in vogue in New York, which involved the cutting away of a portion of the scrotum. He did not think the latter a philosophical procedure, because it simply shortened the bag in which the enlarged veins were contained, and this could be more efficiently done by suspending them in a muslin bag, because the latter was indistensible, while the shortened scrotum, consisting of elastic tissues, would gradually stretch more and more; so that the trouble would eventually return. It did not, therefore, go to the root of the evil. Still more serious and complicated was the operation described by Mr. Lee in the *Lancet* of April 18, 1885, in which he cut open the scrotum and lifted out the veins of the spermatic cord; and in both these operations there was no little danger of erysipelas setting in. In his own operation, the patient was cured in three or four days, instead of as many weeks. It consisted of transfixing the scrotum with a sail-maker's needle (which had a good point, but no sharp edges), and passing between the vas deferens and the veins a strong silk ligature, which, having been carried around the veins, was then brought out at the point of insertion. The ends of the ligature were then tightly secured over a button of German silver or zinc, and the veins being thus strangulated, the ulcerative process went on rapidly.

Dr. Pancoast afterwards spoke of the treatment of stricture of the urethra by his urethrotome, modelled after Mr. Syme's instrument, and the systematic use of dilatation after the cutting; of the advantages of using sutures of pure black silk, dyed with iron; of the treatment of comminuted fractures of the bones of the leg and forearm, and of the neck of the femur in the aged; of an operation for incurvature of the penis, devised by his father; of the treatment of fistula in ano by the antiseptic ligature; and of the removal of chancres with the knife.

The address was discussed by the President, and by Drs. Gouley, Garrish and Newman; and on motion of Dr. Garrish, a vote of thanks was tendered Professor Pancoast.

It was decided that the next special meeting of the Branch Association should be held in Yonkers, Westchester Co., on the second Tuesday in March, 1886.

#### NEW YORK COUNTY MEDICAL ASSOCIATION.

STATED MEETING, October 19, 1885.

DR. FREDERIC S. DENNIS read a paper on

#### FRACTURE OF THE PATELLA, WITH ILLUSTRATIVE CASES.

It was devoted to the treatment of this fracture by wiring the fragments together. Although this operation had been recently revived by Mr. Lister, he said it was originally performed by Dr. J. R. Barton, of Philadelphia, in 1834, and was afterwards practised by McClellan, Logan, and other American surgeons.

At the present day there were two classes who represented surgical opinion. The first considered the procedure perfectly justifiable, believing that when it was

performed with proper antiseptic precautions, it was unattended with danger. Previous to the year 1883, however, out of forty-nine cases in which it was resorted to, two had proved fatal, while in six it was followed by suppurative and ankylosis. But since then the results had been materially better. Dr. Dennis said that he had been unable to collect all the cases of the operation since 1883, but thought that a fair estimate would make them over fifty in number. Among these no deaths had been recorded, and in only three instances, one of which was a case of compound fracture, was there suppuration. Now and then, it was natural that there should be a failure.

The second class of surgeons referred to held that the operation was unjustifiable on account of the great risk involved in opening the joint, and claimed that equally good results could be obtained by the older methods of treatment.

Dr. Dennis stated that he had treated about sixty cases of fracture of the patella altogether himself, and that among those in which he had employed the older methods, there were very few in which there was osseous union and the function of the joint was perfectly restored. He then exhibited a specimen, which he said was unique, showing bony union; the case being one which was treated before the use of wire sutures came into vogue. He also referred to a patient eighty-eight years of age, now under treatment in St. Vincent's Hospital, in whose case bony union had been obtained. He was fully convinced, he said, that the modern antiseptic operation could, as a rule, offer the results of osseous union and a perfect joint; which every surgeon knew the difficulty of obtaining by any of the older methods, and under proper restrictions, he believed it to be an ideal operation. No surgeon should undertake it, however, without a thorough appreciation of the responsibilities which it involved.

In the memorable debate of 1883, Lister claimed for this procedure that it relieved muscular spasm and also gave exit to the blood confined within the joint; and when it was contended that the same results could be more safely obtained by tenotomy and the use of aspiration, he replied that he would put the justifiableness of the operation on the ground that he had faith in his antiseptics. But the reasons of Mr. Lister, he thought, did not wholly justify us in performing it. There were still stronger ones; for while it not only relieved muscular spasm and gave exit to the blood in the joint, it also resulted in every properly treated case in osseous union and unimpaired movements of the joint. By the older methods, as had been intimated, bony union was very rare; and one great reason for this, he thought, was that the layer of tissues in front of the patella gets in between the fragments.

He then mentioned the following three arguments in favor of the newer and bolder treatment: (1) The absence of danger to life and limb. (2) The superior results as regards the functions of the limb and of the joint. (3) The greater rapidity of repair. All these points could be substantiated by clinical evidence. In regard to the first, the absence of danger, he said that since 1883, out of the fifty or more cases, there had not been a single case of blood-poisoning. The less favorable results which had been noted previous to 1883, were, no doubt, due to the fact that the operation was then in its infancy, and all the details required for success were not sufficiently appreciated. It was safe to predict that in the future operation would be en-

tirely free from all danger to life. One great gain since the earlier operations by the new method had been in the shortened time of operating; for while formerly about two hours were required, now thirty minutes was quite sufficient for its importance. A source of delay had, no doubt, been the unsatisfactory way of boring the holes for the sutures in the bone; but with the Archimedian drill which he now employed this could be done very expeditiously.

Perhaps, he continued, the most brilliant test of the operation was to be found in compound fracture, in which no one now pretended to doubt its superiority. To illustrate this he related a case which occurred ten years ago, and which, although the patient recovered with ankylosis of the joint, was then regarded as a triumph of surgery. Quite recently he had himself had a case of compound fracture under treatment. The patient fell from a scaffold, fracturing the patella transversely, and the joint was found to be wide open, and filled with blood. Yet in a few weeks the man was walking about again with perfect ease, and at present the limb was just as good as ever, since he was able to dance, to climb a ladder and to walk ten or fifteen miles. Dr. Dennis said he had had one death following wiring of the patella; but the operation had nothing whatever to do with the fatal result. The patient died in six days, and at the autopsy it was found that the joint was perfectly aseptic; death being due to delirium tremens and Bright's disease. The specimen from the case, which he now presented, was entirely unique, as it exhibited firm bony union in only six days after the operation. No callus was found and the union, he said, was analogous to primary union in the soft tissues.

Second, the superior results as regards the functions of the limb and the joint. Under the use of the older methods separation of the fragments of half an inch was regarded as a very good result, and Malgaigne stated that he had never seen a perfect result after fracture of the patella. Dr. Dennis having enumerated a long list of evils which were likely to follow this accident when treated by the former methods, claimed, in contrast, that with wiring the fragments together a perfect joint, with perfect restoration to usefulness, could be obtained.

Third, the greater rapidity of repair. In a case of his own the patient was walking about in eight weeks, and in one of Dr. Phelps's, in three weeks and three days; while a patient of Dr. Hinton walked nearly a mile at the expiration of six weeks. He believed that in two weeks, as a rule, it would be found that the union would be sufficiently firm to enable the patient to walk. This gain of time was certainly a very important object, not only to the day laborer but to the professional and business man also. Formerly, however, the patient was always laid up for at least three months, and the limb was not strong for two years.

It was true that the Academy of Medicine in Ireland and the Société de Chirurgie had pronounced against the new operation; but he had no doubt whatever that the tide of professional opinion would soon turn in its favor. The case was entirely analogous to that of abdominal section in surgery, in regard to which so complete a revolution of sentiment had occurred. It had been claimed that the knee-joint would be liable to the formation of osteophytes after this operation, but this was merely a fanciful objection. Another objection put forth, was, that rarefying oste-

itis was likely to occur; but he had never seen any such result.

The latter part of the paper was devoted to a description of the technique of the operation. In the first place, he said that wiring the fragments ought not to be undertaken immediately after the accident in simple cases, as it was liable to set up inflammatory action under these circumstances. It was better, therefore, to wait a few days. In compound fractures, however, it was best to perform the operation at once. The strictest antiseptic precautions were invariably to be observed, and among these are the free use of iodiform and ether, the application of bichloride solution, (1 to 2,000) to the parts above and below, and the continuous irrigation of the wound with the same solution from the beginning to the end of the operation. Personally he preferred the transverse to the longitudinal incision, which was the one more commonly adopted. The joint having been laid open, all blood-clots were to be removed, and the anterior fibrous capsule elevated from between the two fragments. The holes in the bone for the sutures, as had been mentioned, were bored with an Archimedian drill, the passage of the wires being assisted by a groove; and no harm came from leaving the latter in the wound. After the wound was closed, a plaster of Paris splint was to be applied, and the patient kept in bed.

Dr. Dennis's conclusions were somewhat as follows:

*First.* In compound fractures of the patella there is not the slightest doubt of the propriety of the operation.

*Second.* In recent and old fractures, under ordinary circumstances and with the patient's consent, it is wholly justifiable.

*Third.* In debilitated patients and those suffering from organic diseases the operation should not be performed.

*Fourth.* It is not an operation which can be indiscriminately performed. It should never be undertaken by the inexperienced or by any one who has not the most entire faith in the efficacy of antiseptic surgery.

*Fifth.* Success depends on the most strict observance of the minutest details of antiseptic procedure.

Dr. Dennis then proceeded to exhibit a number of very interesting cases. The first was his own case of compound fracture where the patient fell from a scaffold. At the end of two months he said he had walked well, and at present it was evident that he had the most complete use of the joints and limbs.

The second case was that of Dr. Fowler, of Brooklyn, which was the first case of compound fracture of the patella treated by the new method in this country, and which, he said, undoubtedly marked an era in the surgery of America. Dr. Dennis's case, just referred to, was the second.

Dr. Fowler's patient was a female, and it was seen that she had a most useful limb; being able to bend it to more than a right angle at the knee. In this case Dr. Fowler had allowed the drainage-tube to remain in position for two weeks, while in his own it had been removed at the end of three days.

The third case was that of a man who had fractured his patella less than three weeks ago, and yet the wound was entirely healed, and he was able to walk about on crutches. Three other recent cases were also exhibited, and all were doing well. Dr. Dennis expressed his regret at not being able to present, in connection with this group of cases, one of Dr. Phelps's, in which

both patellæ were fractured. This patient, he said, was now walking about the streets as well as ever.

DR. FOWLER, of Brooklyn, said that he was always ready to say something in favor of conservative surgery, and he believed the operation to which Professor Dennis had invited attention this evening to be conservative surgery, pure and simple. His own case of compound fracture, which had been referred to and exhibited, was a peculiar one from the fact that the upper fragment became necrosed, and had finally to be removed. After the operation of wiring the fragments together he had found it advisable to leave two drainage-tubes in position, and his object in allowing them to remain for two weeks was, that he believed it to be less dangerous to do so than to be obliged to resort to frequent dressings. He thought that in antiseptic surgery as little change as possible was highly desirable, and in this instance the first dressing was not changed until the expiration of fourteen days, when the drainage-tubes were removed. He had also employed the same method in cases of excision of the knee and other large joints, which are cured in twenty days, with but a single change of dressing, at the end of the tenth day. As to the Archimedian drill employed by Dr. Dennis, he was greatly impressed with its simplicity and usefulness; but even if no such contrivance were made use of for boring the holes, he could not see how such a long time could be required for this as Dr. Dennis had intimated. In his own case he had used an ordinary carpenter's bradawl, and the operation had not been a prolonged one. For introducing the wire through the holes he had employed a cannula. In this operation it was of great importance to remove the fibres of the aponeurotic surfaces from between the fragments, as, if left there they would be extremely likely to prevent bony union.

In cases of secondary suture the method of McEwen, to which he believed that Dr. Dennis had not referred, and which consisted of making saw-toothed incisions of the quadriceps femoris, was of great service in bringing the fragments together. It was the ordinary practice to hammer the twisted ends of the sutures down into the periosteum; but instead of doing this he had suggested turning them in between the fragments, as he believed this would give rise to less irritation. In some cases he had also made use of a rubber bridge, beneath which the wire sutures could be withdrawn entirely after they had served their purpose, if this was desired. In conclusion, he said he could only express his sincere appreciation of the efforts being made in connection with this operation to prove beyond question the superiority of the antiseptic system of surgery, which he considered the most inestimable boon in this department of medicine since the introduction of anaesthetics by means of ether and chloroform.

When the discussion of Dr. Dennis's paper was closed, Dr. H. M. Briggs gave a demonstration of cultures of the micro-organisms of osteomyelitis, after which Dr. F. Forne, a surgeon in the French navy, who was present by invitation, exhibited a new instrument, a true *serre-nœud*, for tightening the knot continuously.

The description of the instrument was read by the Secretary, and Dr. J. W. S. Greely made some remarks upon it, in which he said that it was undoubtedly the best device for the purpose named that had ever been invented. The President, Dr. Charles A.

Leale, then gave a demonstration, under the microscope, of a specimen of nummulites from the foundation stone of Cleopatra's Needle, at Central Park, removed from Egypt to New York in 1880.

### Recent Literature.

*Plumbing and House-Draining Problems; or Questions, Answers, and Descriptions relating to House-Drainage and Plumbing, from the Sanitary Engineer.* With one hundred and forty-six illustrations. New York: The Sanitary Engineer Office. pp. 244. 1885.

The endless and perplexing details which are constantly arising in the process of house-construction and repair are discussed from week to week in the columns of the *Sanitary Engineer*, often in the form of questions or letters of inquiry, with replies by expert authority. These have been carefully selected and published under the title given above. The subjects treated are blunders in plumbing, house-drainage, hot-water circulation, and a variety of kindred topics. Faulty methods are freely criticized, and the proper remedies advised. The book will be found very useful to Health officers, sanitary inspectors, physicians, householders, and all who have to deal with this important branch of work.

*Six Lectures upon School Hygiene, delivered under the Auspices of the Massachusetts Emergency and Hygiene Association to Teachers in the Public Schools.* pp. 201. Boston: Ginn, Heath & Co. 1885.

The appointment of an Instructor in Hygiene for the public schools of Boston, the employment of an expert by the State Board of Health for the inspection of schools in Massachusetts, and the delivery of the lectures named above during the past season, are sufficient proof of a deeper general interest in the physical welfare of the scholar.

The subjects of the six lectures as published are as follows: School Hygiene, by Frank Wells, M.D.; Drainage, by Frank Wells, M.D.; Heating and Ventilation, by Frank W. Draper, M.D.; The Use and Care of the Eyes, especially during School Years, by C. H. Williams, M.D.; Epidemics and Disinfection, by George B. Shattuck, M.D.; The Relation of our Public Schools to the Disorders of the Nervous System, by Dr. C. F. Folsom. The topics named are treated with special reference to their bearing on the health of the teacher and the pupil. They comprise the most important subjects relating to the sanitary welfare of the multitudes of scholars who attend our public schools. They afford a valuable fund of counsel briefly and intelligibly expressed. The book is specially commended to teachers, superintendents of schools, and school committees who desire to be well informed with reference to the health of the pupils entrusted to their charge.

Keith, of Edinburgh, recently came to Boston to give an opinion on the case of a lady who had an obscure abdominal affection. He remained in consultation with the regular attendant about half an hour, confirmed the previous diagnosis in the case and went home with a fee of \$10,000. *Northwestern Lancet.*

## Medical and Surgical Journal.

THURSDAY, OCTOBER 29, 1885.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly, by CUPPLES, UPHAM & CO., Boston. Price, 15 cents a number; \$5.00 a year, including postage, to subscribers in the United States and Canada. Foreign subscribers are charged the postage in addition.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.*

CUPPLES, UPHAM & COMPANY,

283 WASHINGTON STREET, BOSTON, MASS.

### DISSATISFACTION WITH THE CENSUS.

It is discouraging to communities as well as to individuals when they find that their anticipated progress in any desired direction has not been realized. It is therefore no cause for surprise that certain municipalities are disposed to quarrel with the figures of the census enumerators where these figures do not come up to the point which has been set up as the goal of endeavor. The city of Boston finds itself in such a mortifying predicament, caused by having forecasted too liberally the growth of her population since the national census of 1880. At that time the enrollment was 362,839. The fallacy of great expectations was in this case unwittingly contributed to by an estimate of Colonel Wright, the chief of the Bureau of Statistics of Labor, in a compilation of statistics of the city of Boston, prepared for the city government of 1882, in which, taking as a basis the assessors' estimate of polls, he stated that the population of Boston in August, 1882, must have been 400,000. It is somewhat distressing that this pleasant illusion should be shattered by the same hand which in a measure contributed to it. But the unsympathizing logic of arithmetic shows that in May 1885, there were but 390,406 residents of Boston. Is it any cause for wonder that such figures meet with prompt discredit? All theories of what the enumeration should be, deduced from the standard ratios of polls to population, from the recorded births, marriages and deaths, and (shall we confess it?) from some patriotic pride, are violated, and in the face of such overwhelming arguments, the mere evidence of figures is manifestly of little value.

The estimates of the chief of the bureau himself just prior to the enumeration were 410,000 inhabitants for Boston. But the work having been completed and carefully revised without the detection of any material error, he is so little tenacious of a *a priori* theory when it conflicts with mathematical fact as to concede that it looks very much as if Boston has (or at least had in May last) but about 390,000 inhabitants. The true patriots, however, continue to prefer what the chief calls taking the "slate and pencil census in one's office without the aid of enumerators."

His Honor the Mayor, in deference to the claims of opposing schools of statisticians has just ordered an enumeration to be made by the police in conjunction with their regular duties, the returns to be tabulated by the board of assessors. There is doubtless some reason lying below the surface to explain the peculiar fitness the average patrolman has for this sort of work over and above the corps of enumerators employed by the state bureau, many of whom have been engaged on several successive censuses. Recent developments in connection with one of our eastern cities have shown the police to have rather a dangerous aptitude for work at the polling places. If they will transfer their energies from the political to the politico-economical field, they will not only avert a great peril to free government, but will introduce into those zealous contests for supremacy which engross so much of the attention of the western cities, an element of power which will cause Chicago and St. Louis alike to hide in shame their diminished heads.

If these new enumerators do secure a higher census than their predecessors, it will not disprove the accuracy of the returns made in May. It is well known that various influences, some of which emanate from the flowery meads of the country and others from the assessors' office in the city, conspire to reduce the urban population in the month of May, and it is generally admitted that probably some thousands more find a home in the city during the winter months than in the summer. The police enumeration, therefore, even if made with the most exemplary and rigid care will perhaps give results which shall abundantly repay the authors of the project.

In the case of Boston, it is, however, undoubtedly true that the environs have been growing in an increasing ratio at the expense of the city proper, a tendency which has been enhanced by exaggerated taxation. Moreover, the class of citizens who burden the death-rate remains, and the well-to-do, physically and financially, become suburbanites.

Our particular purpose in speaking of this subject is to call attention to the fallacies which result in all vital statistics, to be sure, but more especially in the matter of the death-rate from any modification of the true census made by local pride. Previous to 1875, the death-rates for every census year were presumably correct; but in the intermediate years, the latest census was used as a basis for computing the death-rate; and in these years, of course, the population was generally greater than the last census showed it. Hence the death-rate showed an annual increase up to the time it was corrected by a new enumeration. Since 1875, the custom has been adopted of *estimating* the population for each year, and as the estimates are invariably too high, the death-rate is always figured as lower than it really is; so that when, as this year, it is 24.7 per thousand, it is looked upon as unusually high, even though the mortality has really been no greater than in previous years.

The Health Officer of the Commonwealth has, since the completion of the census, been revising the death-

rates of the various cities in the State for the year 1884, taking for the basis of population the number given by the census of 1880, plus four-fifths of the increase since that time.

A few years ago, the JOURNAL called attention to this source of error in the statistics of the city of Baltimore, where an inflated estimate of population made the death rate unduly low, and where the authorities refused to correct their estimate even by the official figures of the United States Census. St. Louis at the same time was laying the flattering unction to her municipal soul of containing a half million of persons within her limits, when a census showed the actual number to be about 375,000. With such a correction, a death rate which had before been computed as twenty per thousand, would rise to twenty-seven, and the inhabitants, especially if they had been lulled into a false sense of security by previous "doctored" returns, would conclude that the locality was too dangerous to live in.

Why not gracefully admit, if necessary, that your neighboring city has more inhabitants than your own? There are other criteria of excellence than a long census roll; and if you bow to the figures of the regularly authorized enumerators, you can still retain the proud consciousness of superiority in those higher fields in which each community knows itself to excel all its rivals, and which are exempt from the low standards of measurement found in the multiplication table.

#### TROUBLE AMONG ITALIAN SURGEONS.

AMONG Italian surgeons, none probably stand higher than Gritti, Funagalli, Ricordi, and Boccomini, "honorable primaries" of the Milan Hospital Major. Of equal reputation is Bottini, professor of the University of Pavia, who is widely known as a daring and successful operator.

Bottini lately undertook to remove a large sarcomatous tumor from the neck of Madame Corsi, a lady belonging to one of the first families of Milan. The patient sank under the operation, dying about nine hours afterwards. Chloroform was used during the operation, but does not seem to have had the principal share in the fatal result.

In the *Corriere della sera* (one of the daily newspapers of Milan), of the date September 25th, appeared a brief notice of the death of Madame Corsi, in which currency was given to the impression that the deceased was killed by chloroform. The notice ends with the query: "Was this fatality due to the neglect or imprudence of the surgeon?"

The "*Italia*" of September 26-27, publishes Professor Bottini's reply. It cannot be denied that this reply is somewhat aggressive. It is as follows: "The patient had been treated by Dr. Fenini. The physicians of the hospital of Milan had declared the operation impossible, for the reason that a surgeon capable of performing it *was not to be found at every corner of the street*; it was on this account that Professor Bot-

tini was called. He declared that the operation would be a grave one, but that he had successfully performed many of equal gravity. He demanded a prepayment of 1,500 francs; the terms were acceded to. The patient was not killed by the chloroform, as had been falsely stated. She was aroused from the anæsthetic sleep by artificial respiration. The causes of the death were shock and the feeble state of the patient, the gravity of the operation, in which it was necessary to tie the primitive carotid; the anæsthetic may have contributed a little to the untoward issue. It would be great injustice to attribute to negligence or want of skill what was simply a misfortune."

The very uncourteous and foolish allusion to the surgeons-in-chief of the Milan Hospital called forth from that body an indignant rejoinder, of which the closing portion is as follows:—

"As for Madame Corsi (and the same remark will apply to other similar cases where their advice has been asked), the undersigned had advised against an operation, not because they regarded it as especially difficult or impossible, but from considerations of duty, for they are not in the habit of sacrificing the rights of humanity and of science to the cupidity which hides itself under the mask of superior art."

The next scene in the drama is the following communication from Dr. Bottini in the *Milan Journal* for Sept. 29th: "I pray you to announce in your columns that I have to-day entered a complaint (action for libel) against Drs. Rocco Gritti, Cesare Funagalli, Amilcare Ricordi, and Edoardo Boccomini, for the defence of my honor insulted by the letter which they published in the *Corriere* of Sept. 26th, relative to the case of Madame Corsi."

To this announcement the surgeons of Milan replied over their names in the following number of the same paper: "The undersigned, surgeons-in-chief of the Hospital Major, of Milan, with tranquil conscience await fearlessly the threatened prosecution of Professor Bottini."

This, in brief, is the recital of an event which is causing considerable excitement in medical circles in the country where the facts occurred. Whether Prof. Bottini will go on with his libel-suit remains to be seen; meanwhile, he has published in the *Italia* for Sept. 30, a full report of his unfortunate case.

The patient, Madame Corsi, had been suffering for six months from a voluminous tumor of the neck which impeded breathing and deglutition. Bottini regarded it as a sarcoma of the cervical glands, ready to ulcerate, and counselled its ablation. The operation was decided upon, and in due time attempted, Dr. Bottini being assisted by two able surgeons. The chloroform was carefully administered, Junker's anæsthetic apparatus being used. In excising the tumor it was found necessary to ligate the carotid, which was tied, as well as several other large arteries, with little loss of blood. Collapse however set in, and for an hour and a half artificial respiration was resorted to. The patient scarcely rallied from the shock; Dr. Bottini and his assistants were with her nearly all day, doing their ut-

most to avert the fatal result. Dr. Bottini cites two operations performed by him this very year, in which immense tumors of the same kind and similarly situated were extirpated by him successfully; these tumors had been declared incurable by distinguished surgeons. "These successes," he says, "are now forgotten in the opprobrium which is heaped upon me."

Professor Bottini has laid his damages at 1,000 francs against each one of the professors who signed the communication of September 26th ult. It is doubtful if the case ever comes to trial. The quarrel is discreditable to all parties concerned.

#### MEDICAL NOTES.

—That the *os uteri* is the *bone* of the womb seems to be the legitimate conclusion from the title of an abstract in the *Centralblatt für gynäkologie*, to wit, "Anteflexio uteri mit Stenosis ossis interni."

—The exuberant fancy of the scientific editor of the *New York Times* is profoundly stimulated by the microbic foes of man. "Governments," he says, "will doubtless offer rewards for the capture or killing of microbes; and bands of scientific policemen, equipped with powerful breech-loading microscopes, will ceaselessly hunt down the foe. It is undoubtedly a gigantic task to exterminate all microbes; but, after all, it is not much more difficult than the task of exterminating noxious animals must have seemed to the sparse and feeble population of the stone age. Though millions of bacteria may occupy a single drop of water, it must be remembered that a single volley of carbolic acid can kill billions of them. If man is fearless and persistent, he will conquer the microscopic animals, and virtually exterminate them. The time may even come when scientific persons will establish parks in civilized regions for the preservation of microscopic game, and petition for the passage of game laws, making it a misdemeanor to kill a bacillus during the breeding season. Sportsmen will travel thousands of miles in search of game and of rare sport among the bacteria of Central Africa and the Indian jungles. Some scientific Gordon Cumming will describe, in thrilling words, a wild gallop over an African plain in chase of a predatory bacillus; and some scientific Baker will tell us of the midnight hours spent in waiting by the side of a malarious Indian pool for a stray microbe, and of the awful moment when the microbe bounds out of the jungle, and the hunter discovers that his carbolic-acid cartridges are wet, and he can defend himself only with his travelling-flask."

#### BOSTON.

—The Board of Health of Boston, has been investigating the cases of typhoid fever now existing in the city and has sent circulars to a number of prominent physicians, asking them to ascertain the causes of the disease as far as possible, and report the result to the board, giving particular attention to the whereabouts of the patient just before the disease appeared. More recently the city board of health made out a list of all

persons who are now ill in Boston with typhoid fever, and a personal canvass was caused to be made among them. Especial attention has been given to the kind of water the sick people had been drinking. In a great many instances they found that the patients had not been out of town, but it was learned that they had visited West Roxbury Park and had drunk water from the numerous wells in the park. Samples of water from about thirty wells in the park have, we understand, been sent to Professor Wood of Harvard University for analysis. In some instances the water was found to be of excellent quality, but the water from many of the wells was very impure, and unfit for domestic purposes, and the physicians feel assured that the water has caused considerable typhoid fever.

### Miscellany.

#### DEATHS FROM CHOLERA IN SPAIN.

According to the reports transmitted to the National Board of Health the total number of reported cases of cholera in Spain from March 4 to September 17, was 257,684, and the number of deaths 76,031; making a mortality of a little over thirty-seven per cent. The number of cases in Italy from August 4 to September 18, was 165, and the deaths 89.

#### NEW BUILDINGS OF THE MEDICAL FACULTY OF MCGILL UNIVERSITY, MONTREAL.

THURSDAY, October 22, the new buildings of the Medical Faculty of McGill University were thrown open to the public. At the inaugural ceremonies appropriate speeches were made by Professors Pepper and Osler of the University of Pennsylvania, the principal, Sir William Dawson; the chancellor, Senator Ferrier; the dean, Dr. R. P. Howard, and others. In the evening a large company of medical gentlemen, professors of the college, and friends and benefactors of the institution sat down to dinner at the Windsor Hotel.

The buildings as now arranged have the following features:—

The main hall on the first floor is 126 feet long, with a room 28 feet long at the end of it, giving a total length from front to rear of 164 feet; also by the fact that the building covers 13,930 square feet. On the ground floor the library, which contains over 10,000 volumes, will now consist of two rooms, the additional room being 30 x 22. On the opposite side of the hall is the museum, which will now be connected with an extensive additional room by a small chamber, in this way almost doubling its present capacity. Next to the students' reading room is the private room of the professor of physiology. This is chiefly for the purposes of experimental work of the professor himself. Here, also, will be kept the valuable apparatus of this department, which has been extensively added to, and is now thoroughly efficient. Opening off the laboratory is the "balance room" and private room for the professor of chemistry. On the opposite side of the main hall is the large lecture theatre for the classes in these two branches. The room is hexagonal in shape, and its widest part measures 76 feet. It is lighted by a skylight and three windows to the rear of the students, which also serve admirably for ventilating purposes. It will seat comfortably 275 persons. Beneath the higher seats are four rooms, each 8 feet high and 10 feet wide. The professor of therapeutics will occupy the first two rooms, one of which will be for the convenient performance of his duties as registrar. On the second story, opposite the main staircase is the dissecting room. This will be now 72 feet long, and will be provided with 20 tables. The room will be well lighted—by daylight from two skylights, as well as windows from three points of the compass; and at night there will be both electric lights and gas. The adjoining laboratory will be furnished with 30 microscopes, also micro-

scopes and other apparatus for practical work. In the annex on this floor will be a large lecture room, capable of seating comfortably 300 students. Its measurements are 56 x 40. This theatre will be utilized as the anatomy lecture room, besides other purposes. Separate entrances are provided for the students. The professor of anatomy will have his room opening off this theatre. Beneath the higher seats will be rooms 8 feet high and 12 feet wide at the narrowest part. Of these the pathologist will utilize what he may require.

#### RESIGNATIONS FROM THE ORGANIZATION OF THE PROPOSED CONGRESS.

THE following additional resignations from the organization of the International Medical Congress are reported: Dr. H. F. Campbell of Georgia, late president of the American Medical Association, has resigned the vice-presidency, and Drs. E. O. Shespeare, of Philadelphia; H. G. Beyer, J. M. Flint, J. S. Kidder, U. S. N.; John J. Mason, of Newport; and George W. Major, Montreal, have resigned their positions in the various sections. Dr. R. A. Kinloch, of South Carolina, withdraws from the executive committee, in a letter expressive of shame and indignation at the course pursued by that body. The New York *Record* thinks "the Congress, at present, looks to be very much such a thing as Bright's disease, viewed from the standpoint of Dr. Goodheart, that is, a magnificent scheme of decay."

### Correspondence.

#### LETTER FROM STRASSBURG.

#### THE FIFTY-EIGHTH CONGRESS OF GERMAN NATURALISTS AND PHYSICIANS.

STRASSBURG, Sept. 27, 1885.

MR. EDITOR.—A fortunate opportunity allowed me to become a temporary member of the recent Congress, in Strassburg, of German naturalists and physicians. The Congress occupied nearly an entire week, namely, from the 18th to the 24th of September. That I could become a temporary member was due to the sensible arrangement which admits a physician or scientific man of any country to the Congress as a "*Thelinkamer*." To ordinary associates or "*Mitglieder*," is issued a red, to "*Thelinkamer*" a green card of membership. Both cards exact the same fee of twelve marks, \$3; both give equal right of admission to every section of the Congress, to all the festivities, and the privilege of bringing one lady to general and social meetings, and also equally entitle their respective holders to all printed matter published by the Congress. The latter, he said, is far from insignificant in quantity, for the recent Congress not only supplied a *Tagblatt*, or printed *resumé*, of the proceedings of the entire assembly in all its sections, but also two very handsome books of folio size, averaging 160 pages each, abundantly illustrated and beautifully printed. One gives the "History of Medicine and its Schools in Strassburg from 1197 to 1872," with most interesting anatomical illustrations from various works issued during these four centuries; the other is a "*Festschrift*," dedicated to the Congress and presenting a history, pictures, plans, and the costs of the medical and scientific, together with the general University buildings of the present day.

Of themselves these two fine volumes are well worth the cost of a card of membership. The first number of the *Tagblatt* appeared on the morning of the first day and comprised a programme of the doings of the entire week, giving under each of the twenty-five sections the titles of papers to be read and names of the readers; a list of such *Mitglieder* and *Thelinkamer* as had already announced themselves and their residences; a list of hotels, pensions

and private houses in which members might lodge, with all needful information in regard to cost of meals; details of the evening festivities and other useful matter. The second *Tagblatt* contained the doings of the previous day, papers being given in full, or in synopsis, according as authors desired, and a satisfactory outline of the discussions in each section. And thus each day appeared a new *Tagblatt* which also included names of members who arrived the previous day and their residences; likewise such new information, invitations, suggestions, and remarks as the Committee had to offer. A much more concise and sensible method than that of handbills or the *civis voce* in the sections. In short the *Tagblatt* was a newspaper confined to the work and movements of the Congress. As yet I am puzzled as to how the Congress could afford this amount of printed matter, and yet pay the other expenses of the week from the proceeds of the cards. It is probable, however, if a dinner similar to that of some of the American State Societies, had been given by the Congress, the *Tagblatt* and the books could not have been published. The only occasion on which refreshments were provided was the reception at the *Stadthaus* in response to the invitation of the *Burgomeister* on behalf of the city. Beer, bread, and cold meats were furnished at a minimum cost in one of the ante-rooms of the places of meeting. This was a great convenience to many of the members. Involuntarily but quite consistently I have given beer the first place. Another room was devoted to those who wished to write letters. Here also telegrams and letters were received and forwarded and correspondence mailed.

The statutes of the Congress announce that the chief object of the Society is to give physicians and scientists of Germany opportunity to make the acquaintance of each other. The president and secretary must be residents of the city in which the Assembly meets, and must conduct all business until the next Congress. Those who hold cards, whether as "*Mitglieder*," or "*Theilnehmer*," have the privilege of taking part in all discussions and also of voting on all propositions.

Those who read inaugural dissertations are not allowed to read papers in the sections. Several inaugurals are read at each of the two general meetings of the members.

In many respects Strassburg proved a felicitous place for the Congress. Very many of the members had never before had opportunity to inspect the noble buildings of the University of which Germany justly is so proud. To many the recent acquisition of Alsace by Germany gave the city an additional interest. Others, however, felt that the general tone of the meeting was much less cheerful than that of the previous yearly meeting at Magdeburg. They accounted for this by the depressing effect of the universal mood of the old inhabitants.

Section-work was interesting, the various sections naturally differing somewhat in this respect. The salient and prevalent fault of section-work was the great irregularity in the length of time occupied by readers and disputants. The almost military and absolute system of the French Congress of Surgeons in April, made this error only the more striking. Some of the readers occupied a full hour. The result was, much uneasiness, much inclination to sleep and very decided criticism. But to my surprise no member offered any objection in open meeting. In private, however, dissatisfaction was universally expressed. Indeed, the prolixity of many of the readers gave a very slow and tiresome tone to the sections in which this fault prevailed. Twenty minutes is certainly a period long enough for the presentation of any subject, especially when made to men who know how to read. The amount of work accomplished by the French Congress was large even in proportion to that achieved by the German Congress of last week, and yet every paper gave a perfectly clear statement of its subject and disputants were able to complete their arguments within five minutes. One feature of section-work in the Strassburg Congress was extremely agreeable—no one reader used his manuscript. The amount of discussion varied greatly in different sections. In the pathological section disputa-

tion was very animated. It was rather striking to see our old lion, Virchow, bearded in his own den by a much younger pathologist, and he evidently thought so himself, for he quickly showed that the fire of youth still glowed within him. Those who have studied in Berlin well know what that fire is. The mere report that Virchow had fought a pathological battle was sufficient to crowd his section at its next meeting. His beard is now full and wholly gray, almost white, but he is still the brilliant Virchow of old, and a conversation with him leaves the deep impression which he has ever created. In his inaugural I thought him perhaps less concentrated than he was fifteen years ago, but his voice, his manner and his clear diction are quite the same. A wonderful man! It is a common saying here that Nature broke her mould at Virchow's birth, for his sons are very ordinary men.

Meanwhile in the clinical section discussion was surprisingly infrequent. In the section for surgery it was much more animated, as also in that for nervous diseases and diseases of the mind. Here Erb, of Heidelberg, presented most exquisite microscopical preparations in illustration of his paper. In the section for skin diseases and syphilis there was warm interest. Doutrelepoint read a paper entitled "*Demonstration von Bacillen bei Syphilis*," which freely showed his conservatism. I will here take the occasion to modify the statement in a former letter that Doutrelepoint has never discovered syphilitic bacilli within cells. More correctly, he has found them in cells but far more frequently outside the cells. The former statement has been true but is so no longer. Naturally I cannot give details of the doings of twenty-five sections, but it will be of interest if I state what these sections were. This will give a general idea of the highly scientific character of the Congress. In their order upon the programme the sections were thus entitled: (1) "Mathematics and Astronomy;" (2) "Physics;" (3) "Chemistry;" (4) "Pharmacy;" (5) "Mineralogy and Geology;" (6) "Geography;" (7) "Botany;" (8) "Zoology;" (9) "Anatomy and Anthropology;" (10) "Physiology;" (11) "Pathological Anatomy and General Pathology;" (12) "Pharmacology;" (13) "Clinical Medicine;" (14) "Dermatology and Syphilis;" (15) "Surgery;" (16) "Gynecology;" (17) "Children's Diseases;" (18) "Ophthalmology" (Knapp, of New York read a paper); (19) "Neurology and Mental Diseases;" (20) "Affections of the Ear;" (21) "Laryngology;" (22) "Hygiene;" (23) "Military Hygiene;" (24) "Veterinary Medicine;" (25) "Agriculture." The business of the sections was conducted with a singular lack of formality. In the choice of a new chairman, which was done at every sitting (morning and afternoon), in a vote upon change of hours, upon adjournment, etc., the presiding officers simply called upon the members for their opinions, and dozens spoke at once, until the matter in hand resolved itself into a quiet chat between chairman and members, and thus decisions were made without any count whatever, the general tone of the audience giving the chairman his cue. Not in a single instance was his decision questioned.

The first meeting of the members was social and held in the evening. At the first general session the next day the large hall of the fine University building was crowded. Professor Kussmaul, the President, delivered an eloquent address of welcome in which he gave a general history of the University of Strassburg from its formation to the present day. After a welcome from the *Burgomeister* and the rector of the University, the meeting proceeded to elect Berlin as the place for the next Congress, in spite of the warning of Virchow that the difficulty of uniting in a city so large as Berlin was one the reality of which the members would learn to their sorrow.

A most spirited biographical sketch of the lives of Frerichs and Henle by Rühle, of Bonn, received the commendation of the president. Professor Rühle being ill and absent, the audience was referred to the forthcoming *Tagblatt* for this charming sketch of "Jacob Henle, a King among Anatomists, and of Friedr. Theod. Frerichs, a King among Clinicians, two princes in the kingdom of medical science and erudition."

Professor Weismann, of Freiburg, then delivered a profound and powerful address on "The Impotence of Genetic Reproduction in the Theory of Selection."

The following two days were devoted wholly to section-work. A Sunday fell between them, on which day the entire Congress repaired to Zarban, by rail, and spent the day in and about the ruins of an old castle, situated upon a hill from which the outlook satisfied to overflowing the nature-loving senses of the visitors. The previous evening and late into Sunday morning, the Congress revelled in the brilliant reception given in the Stadthaus by the Burgo-meister. The finest of military bands, an orchestra which supplied dancing music, abundance of wine, champagne and ices for ladies and the gentlemen who accompanied them, rivers of beer and the solids so dear to the German palate for the men, not thus favored, electric lights, fountains and flowers, made this the most predominant of the social gatherings. Other evenings were spent at the "*Rheinlust*," a very attractive restaurant with garden, just out of the city and overlooking the river Rhine; or in the rooms of the "*Ciel-Casino*," a resort within the town. The members chose their evening rendezvous according to programme suggestion and all went merry as a marriage bell. The amount of beer consumed on these occasions, something undoubtedly fabulous, may be hinted by the fact that the Congress numbered nearly one thousand individuals. The "*Luxhof*" was the midnight resort of scores after the close of the stipulated festivities, and gray-haired professors and *privat Dozenten* shouted "*Prosit!*" to each other from table to table. But let it be said that joyousness and Gambrinus interfered not the slightest with the earnest devotion to the work of the day. At evening every countenance was jovial and happy. In the morning and throughout the day the seriousness of science was upon every face. Thoroughly characteristic, this, of the hearty earnestness of the German whether at work or at play.

Many valuable papers were read before the sections, but their number was too great to admit mention even of their subjects. Cocaine naturally received attention, and by a coincidence its usefulness in whooping-cough was discussed in several sections. Prior, of Bonn, read an excellent paper on this use of the drug, and showed by many tabulated cases that application of cocaine to the interior of the larynx three times daily, in the majority of cases, shortened the duration of the attack several weeks. A similar application is recommended in bronchial asthma. The price of cocaine in Germany, by the way, has very notably diminished. Prior suggests Finkler, who in his section announced the discovery of the Finkler-Prior bacillus in a new endemic of cholera nostras, which occurred in Bonn only a few weeks ago. This announcement was made as a refutation of the assertion that Finkler and Prior discovered their bacillus in old and foul discharges. This is not the case. The dejections which they have examined have always been fresh. Their recent publication upon this subject has won for them among noted men many believers in the close relationship between Koch's bacillus and theirs; and German physicians who procured and examined the discharges of individuals who suffered from the so-called cholera Asiatica in Paris last winter, now assert that the bacilli found in these discharges indicated, by the rapidity of their growth in culture fluids, that the disease was cholera nostras and not Asiatic cholera.

A most interesting display of new electrical apparatus was made before several of the sections. Among them the most interesting and novel being a small and convenient lamp to be worn on the forehead precisely in the manner of a laryngoscopic head-mirror and which, without disturbing the eyes of the patient, brilliantly illuminates the larynx. The battery is small. The lamp burns 700 hours, and the incandescent material can easily be renewed. A tiny electric lamp for illuminating the cavity of mouth and pharynx, and another for the purpose of enabling one to use the microscope by white light in the evening, were also shown. A prospectus with illustrations can be obtained from R. Blümsdorf, Institut für Elektrochirurgie, Frankfurt, Main.

The exhibition of surgical and orthopaedic instruments and applications was very fine, occupying three rooms. Upon invitation of Professor Recklinghausen those members who chose to do so visited the Pathological Institute under his guidance, and Recklinghausen, with a plan of the building in his hand, carefully described the convenient and extensive arrangements of the institution. A similar visit was made to the Physiological Institute where very costly, very beautiful and exquisitely delicate physiological apparatus was explained. The most striking and delicate of these was an instrument (constructed by Professor Knoll, of Prag, and who is about to describe it in print) for studying the movements of the eye in cerebral anæmia. By means of this instrument the ocular movements are traced upon paper or smoked isinglass.

The second general meeting of the members occurred on the morning of the fourth day and was rendered especially attractive by the address of Virchow upon "Acclimatization." As I have already remarked, Virchow in the delivery of this inaugural gave sufficient evidence that his mental and physical power is as vigorous as of yore. It may, however, be repeated that on this occasion his statements seemed less concentrated, somewhat more diffuse than used to be his manner. The address naturally won the closest attention. German lay journals have since sharply criticized Virchow upon the position he took in regard to German colonization, and it is a painful fact that his political views led him to announce opinions not only quite at variance with the best interests of the German folk who are already in the colonies, or who incline to settle in one or the other of them, but which lack the sound sense which has given Virchow much of his fame. He was followed by Professor Pechnel-Löschke, of Jena, who addressed the Assembly upon "The Agricultural Management of Tropical Regions."

The closing day was devoted by the various sections to excursions in which each section chose its own trip. I fancy that the majority of the members took a homeward train.

In many respects this Congress may be compared to the annual meeting of the American Medical Association which however, in conversation with physicians on this side of the Atlantic, I almost blush to name. Nevertheless, the general character of the German Congress occupies a much higher level. It is wholly free from wire-pulling and medical politics. Its most active members are the most famous and the most cultured men of Germany. The character of papers read in general meeting is far more intellectual than anything which is produced by our national body of physicians. Its section-work is likewise more cultured and therefore more valuable. The active medical disputants are men like Virchow, Bardeleben, Klebs, Recklinghausen, Quinke, Nodding, Schützler, Czerny, Freund, Winkel, Hoppe-Seyler, Ranke, Fittig, Lucka, Kussmaul, Ruhle, Doutelepoint, Erb, Trautmann, etc. The meeting is one not only of the highest scientific character, but one whose atmosphere is warm with brotherly feeling and absolutely free from either jealousy or envy. The noble University building provided abundance of ante-rooms, for the many sections, and the business management of the Congress was perfect in its kind. Card of membership was a triple folder and gave the programme; a fine map of the city, the names of the streets being distinctly printed, and the locations of public buildings, hotels, restaurants and beer gardens being numbered to correspond with a list of these; a schedule of dress-charges and a time-table of the street railroads. It was extremely convenient and well arranged.

In closing, I am glad to be able to say that the feeling, so widely disseminated here three months ago, that the possibility of an International Congress in America in 1887 had vanished, becoming displaced by a belief that the unworthy *comp'd etc* which was sprung upon physicians at large by a few sordid heads will be effaced, and that the coming Congress will be a success. This change of sentiment is largely due to the editorials of our best medical journals, and to the manly course adopted by the leading

physicians of our larger cities. The action of the minority at the late meeting of the American Medical Association at New Orleans is, I fully believe, now clearly understood, and European physicians rely upon the efforts of our physicians of the better class for a timely settlement of the whole matter. What is said here in regard to that unenviable minority may safely be left to the imagination. The world-wide contrast between the animus of these very cheap specimens and the fraternal and unselfish unity so strikingly evident at the German Congress, leads me heartily to wish that the doings of the Shoemaker malcontents might have been kept closely hidden as "a skeleton in the closet" of our medical family.

H. O.

### A CARD LEDGER.

MR. EDITOR:—In any system of bookkeeping which a physician may adopt, it is desirable to have an arrangement by which he can easily tell what is due him.

I suggest a method by which the *unpaid* accounts are placed by themselves.

This can be readily done by cards, such as are used for library catalogues—each debtor having a separate card. The name is placed at the top of the card like the names in an author's catalogue. When the accounts are charged off from the visit book, each one is placed in its proper alphabetical position, and so remains until paid.

When full payment has been made, the card is filed with others of its kind, to be returned to the unpaid list again when a new obligation is incurred. The same card may be used in this way till it is filled, and both sides may be used if preferred.

As regards ruling, I prefer that of the ordinary business ledger, but any style may be adopted, the cards being cut of suitable size and shape.

C. W. Clark, No. 75 Hawley St., Boston, has goods of this character. A covered tin box, containing 500 cards (3 x 5 inches), with the usual fittings, is sold for \$2.75; but almost any printing-office will furnish cards of such size and ruling as may be desired.

Some physicians keep a file of duplicate bills, to furnish ready reference to those that are unpaid, and some have memorandum slips for the same purpose, but I think it is best of all to have the ledger itself placed on movable cards.

WM. H. LATHROP, M.D.

LOWELL, MASS.

### THE ANIMAL VACCINATION BUSINESS.

MR. EDITOR:—Before I had seen the *Medical and Surgical Journal*, of October 8th, which contained Dr. S. C. Martin's article, my attention was very forcibly directed to it by an exceedingly intemperate and pyretic letter from a physician belonging to a neighboring State Society, calling upon me "at once to deny the claim of priority of the introduction of vaccine virus," and invoking upon my head "the scorn and contempt of the medical profession of this country" if I did not do so. After reading a page of abuse of this kind (which was subscribed "Yours respectfully") I naturally read the article as soon as I could recover my breath, and now feel called upon to make a reply.

The following is the portion of the article in the *Boston Post* of September 15, which relates to the Drs. Martin and myself.

In 1867 Drs. Waterman and Garceau of Boston attempted to renew the vaccine seed by importing lymph from Berlin. As soon as it was received they purchased some fine healthy calves and vaccinated them with the imported seed. The experiment was a perfect success, and during the small-pox epidemic in 1867 they supplied the citizens of Boston with from 10,000 to 20,000 points. Very naturally after the scare was over the demand fell off and the business became unprofitable, and after following it for a little over two years they abandoned it.

In 1870 Dr. Martin, of Roxbury, following in the wake of Drs. Waterman and Garceau, opened a stable and vaccinated

several calves with imported seed received from Beaugency, France. In this connection a curious incident is noticed. The existence of kinepox, although well known to milkmen of this and the old country, grew less frequent after Jenner's time. But shortly before Dr. Martin opened in Roxbury, a well-defined case showed itself on a fine calf in Beaugency, France, and it was from seed taken from the udder of this animal that Dr. Martin commenced operations. With his inoculated calves he commenced the product of animal virus in this country on an extended scale. The elder Dr. Martin died several years later, and the business has been continued by his son, Dr. Stephen C. Martin, up to the present time.

There was a manifest error here. It should have read that Drs. Waterman and Garceau imported lymph from Beaugency (not Berlin) in 1872 (not 1867), and followed in Dr. Martin's wake. I knew nothing about the authorship of the article, furnished no information for it and consequently did not feel called upon to make any counter-statement. The errors and misstatements of the daily newspaper press, when dealing with medical matters, are too frequent and too flagrant for any man or body of men to attempt to hold themselves responsible for them.

Dr. S. C. Martin replied to the above extract by an article in the *Boston Post* of September 21st, headed:—

### A CORRECTION.

To the Editor of the *Boston Post*:—

Will you kindly permit me to correct an important error in the article on "Vaccine Virus," in your issue of Sept. 15? It is there stated that Drs. Waterman and Garceau introduced animal vaccination into Boston in 1867, and that Dr. Martin "followed in their wake." True animal vaccination was first introduced into this country in 1870, by my father, the late Dr. Henry A. Martin, the well-known writer and authority on the subject of vaccination. This is universally acknowledged by the profession and has never before been questioned. It is proper, however, that the public should not be misled, and that Dr. Martin's well-earned honor of introducing the new method and causing it to be generally adopted, should not be impaired. Neither of the gentlemen named will, I think, dispute the fact.

Very respectfully,

STEPHEN C. MARTIN, M.D.

No. 27 Dudley Street, Sept. 20, 1885.

This "correction" stated the case properly for the benefit of the general public. The medical profession, of course, needed no such corrective information on a subject with which they had already become very familiar by reason of the many repetitions of it, by the late Dr. Henry A. Martin, in medical articles and circulars for the past fourteen years.

Neither Dr. Garceau nor I disputed this "correction," and the subject should have ended here. But no, further "correction" was needed, and Dr. S. C. Martin began to write letters, and, because he could not induce me to deny a claim which I had never made, he prints his letters and my replies with an appendix, and asks for the candid (sic) consideration of his brethren.

A few facts about the vaccine business:—

Dr. Ephraim Cutter vaccinated cows and furnished the lymph to the Federal Army during the late Rebellion.

Dr. Henry A. Martin in 1870 introduced into America the Beaugency stock, true animal vaccination so-called.

Dr. T. Garceau and Dr. T. Waterman in 1872, imported some lymph from Beaugency in capillary tubes and began the practice of animal vaccination.

In the early autumn of 1881 I was requested by some reputable physicians of this city, who knew that I had formerly been a propagator of animal vaccine virus, to keep a supply of some reliable virus for their convenience. On inquiry I ascertained that the Boston Board of Health had selected the lymph of the N. E. Vaccine Company and were using it exclusively. They had used no other for the past four years. I also chose their virus and became their agent.

During the past four years I have seen the gentleman, whom Dr. Martin styles "one Dr. William C. Cutler," three or four times. I do not know whether he is a physician or not, but I do know that he is a liberal, honorable, business man. There has been an open quarrel, in a business way, between him and the Drs. Martin for a long time, with which I have nothing to do.

Animal vaccination and the supply of vaccine virus is a business or trade. There is no mystery about it. "The proof of the pudding is in the eating," and he who supplies the most reliable goods will command the most sales. It would indeed be an insult to the medical profession to suppose that they are not intelligent enough to draw their own conclusions as to who sells the best virus, or that they will rely implicitly on the dictum of any individual propagator.

Unless I am very much mistaken the late Dr. H. A. Martin did not dispose of his virus gratuitously, but *sold* it in the open market. Dr. Stephen C. Martin does likewise.

This is at least the second time (*cide New York Medical Record*, April 11, 1885) that Dr. S. C. Martin has appeared in the medical press apparently for the sole purpose of slandering a competitor and advertising himself.

I think I may seasonably raise the question whether he possesses any vested hereditary or acquired right to be considered the epitome of all that is "best and uniformly fresh and reliable" in the business of animal vaccination. "An honest tale speeds best, being plainly told."

Very truly yours,

THOMAS WATERMAN, M.D.

146 Boylston St., Boston, Oct. 20, 1885.

## LAPAROTOMY FOR INTESTINAL OBSTRUCTION IN AN ADULT.

COLUMBUS, OHIO, October 24, 1885.

MR. EDITOR.—In the *Boston Medical and Surgical Journal* of September 3d, 1885 (No. 10), is an article by Dr. Joseph B. Heald, on a "Successful Case of Laparotomy for Intestinal Obstruction."

In ending his interesting report of the case he states, that to the best of his knowledge, it is the "first successful case of laparotomy for intestinal obstruction in an adult, that has been reported in this country."

Having made and reported a successful case of laparotomy for the same condition, prior to his report, I have the honor to forward to you the article, thinking that a connection of the statement as to its being the *first successful case*, may be of interest for statistical purposes, if such it proves to be.

I remain very respectfully,

FRANK S. TRIPP, M.D.

Dr. Tripp's case was published in the *Louisville Medical News*, January 17, 1885, the operation having been performed November 5, 1884. — [Ed.]

## REPORTED MORTALITY FOR THE WEEK ENDING OCTOBER 17, 1885.

Deaths reported 1,544; under five years of age 490; principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrhœal diseases) 293; consumption 219; lung diseases 91; diphtheria and croup 110; diarrhœal diseases 65; typhoid fever 42; malarial fevers 17; scarlet fever 15; cerebro-spinal meningitis 11; whooping-cough 12; puerperal fever three; measles two; erysipelas two; small-pox one. From malarial fever, New York eight, Baltimore seven, Philadelphia two. From scarlet fever, Philadelphia seven, Providence and New York two each, Boston, Charleston, Cambridge and Chelsea one each. From cerebro-

spinal meningitis, New York five, Philadelphia, Baltimore, Worcester and Somerville two each, Salem one. From whooping-cough, New York five, Philadelphia and Providence two each, Cambridge and Chelsea one each. From puerperal fever, New York two, Cambridge one. From small-pox, New York one. From measles, Boston two.

In 110 cities and towns of Massachusetts, with an estimated population of 1,338,119, population of the State 1,941,651, the total death-rate for the week was 15.57 against 14.06 and 15.05 for the previous two weeks.

Population by State Census, of May 1st, 1885.

The meteorological record for week ending October 17th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole of the United States Signal Corps:—

Week ending	Barometer.	Thermometer.				Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM OCTOBER 17, 1885, TO OCTOBER 23, 1885.

MCPARLIN, T. A., surgeon and colonel. Directed to await further orders in New York City. Letter from A. G. O., October 19, 1885.

VOLCM, E. P., surgeon and lieutenant colonel. Assigned to duty as attending surgeon, headquarters, Department of Platte, Omaha, Neb., relieving Assistant Surgeon Wm. C. Shannon. S. O. 103, Department of Platte, October 15, 1885.

JIEGER, ANTHONY, surgeon and major. Directed, in addition to his present duties as member of Army Medical Examining Board, now in session in New York City, to perform the duties of attending surgeon in that city. S. O. 240, A. G. O., October 19, 1885.

BAILEY, JOSEPH C., surgeon and major. Granted leave of absence for twenty days. S. O. 225, Department East, October 19, 1885.

#### SOCIETY NOTICES.

SUFFOLK DISTRICT MEDICAL SOCIETY.—There will be a stated meeting on Saturday, October 31, 1885, at 7.45 P.M., at 19 Boylston Place. Papers: Dr. Robert Amory, "Electrolysis and its Therapeutical Applications." Dr. Vincent Y. Bowditch, "A Case of Phthisis with numerous Bacilli: Complete Arrest of Disease." Dr. Henry G. Marey, "Western North Carolina as a Health Resort." Incidental business: Choice of a Committee of five to prepare a list of Candidates for Officers of the Society. Supper after the meeting.

CHARLES M. GREEN, Secretary.

The Secretary is about to prepare a new directory of the Society; members are therefore requested to notify him immediately of any recent change of address.

WASHINGTON, D.C., OBSTETRICAL AND GYNECOLOGICAL SOCIETY.—At the Annual Meeting of the Washington, D.C., Obstetrical and Gynecological Society, held on October 16, 1885, the following officers were elected for the ensuing year: President, Dr. A. F. A. King; Vice-Presidents, Drs. W. W. Johnston, and J. Fisher-Johnson; Recording Secretary, Dr. C. H. A. Klein-schmidt; Corresponding Secretary, Dr. S. S. Adams; Treasurer, Dr. G. B. Harrison; Committee on Business, Drs. C. E. Hagner, Lachlan Tyler, and S. S. Adams; Committee on Admissions, Drs. G. N. Acker, H. H. Barker, and H. D. Fry; Committee on Publications, Drs. T. C. Smith, J. K. Brownell and Klein-schmidt; Committee on Pathological Specimens, Drs. Acker, W. W. Johnston, and Harrison.

#### OBITUARY.

Dr. William Workman, of Worcester, died October 17th, after several weeks' illness, in the eighty-eighth year of his age. He was of Scotch-English descent, and was born at Colerain, Mass., in 1798. He studied and finished preparation for college at Hopkins Academy at Old Hadley, under the direction of Rev. Daniel Huntington. Owing to ill health he was obliged to give up the college course, and finally began the study of medicine in 1822 in the office of Dr. Seth Washburn, at Greenfield. In the fall of that year he attended lectures at the medical department of Harvard University, and continued his studies there and with Drs. Flint and Mather, of Northampton, till August, 1825, when he received the degree of M.D. from Harvard. He immediately began practice in Shrewsbury, where he remained

for ten years. In 1835 he came to Worcester, and continued in the practice of medicine till 1863, when he retired. He became a member of the Massachusetts Medical Society in 1831, was elected councillor of the society in 1840, which position he held till 1864. He delivered the annual address at the annual meeting at Fitchburg in 1852. He was also a member of the American Medical Association, and was frequently a delegate at its earlier meetings. For many years he took a prominent part in the proceedings of the Worcester District Medical Society, serving on important committees, and occupying at one time or another all of its offices except that of librarian. He always retained his interest in the society and two years ago gave it his medical library. He was also a member of the Worcester Medical Improvement Society.

His horizon was by no means, however, bounded by his profession. From 1840 to 1850 he served on the "Board of overseers of schools for the centre district," the latter part of the time as secretary of the board, and also for several years on the public school committee, after Worcester was made a city. He was president of the Lyceum Society, before which he read a number of papers on scientific subjects, was trustee of the Worcester County Institution for Savings from 1848 till 1873, and was director in the People's Insurance Company of Worcester, from 1860 till its dissolution, after the Boston fire in 1872. In 1862 he was appointed by Governor Andrew trustee of the Worcester Lunatic Hospital, and was re-appointed by Governor Bullock in 1867. In 1872 he declined further service, though again re-appointed. In the time of the seven days' battles, in 1862, Dr. S. G. Howe, in behalf of the sanitary commission, telegraphed for volunteers to act with that organization in caring for the wounded. Although then sixty-four years of age, he at once offered his services, and went to Fortress Monroe as surgeon-in-charge on a government transport. He was a prominent member of the Union Church and Society, uniting with it in 1840, and always maintained an upright and consistent Christian character. After his retirement from active life he continued his habits of study, devoting much time to the compilation of books, of which he was ever fond and to which he had desired leisure to give his attention.

#### CORRECTION.

##### TUBERCULOSIS OF THE PHARYNX.

MR. EDITOR, DEAR SIR.—In the report of the discussion on the paper of Dr. DeBlois on the above subject in your issue of 22 inst., I am made to say that "cases of tuberculosis of the pharynx had been rarely reported, and that I had never seen but one case," etc. This should read *primary* tuberculosis of the pharynx. Secondary tuberculosis of the pharynx, as Dr. DeBlois' cases apparently were, is occasionally seen by every laryngologist.

Yours truly,

FREDERICK I. KNIGHT.

Boston, Oct. 23, 1885.

#### REMOVAL NOTICE.

NEW ENGLAND MEDICAL MONTHLY.—The Editor's address hereafter will be Newtown, Conn., instead of Sandy Hook. Send exchanges and all matters pertaining to the literary and editorial department to this address.

#### BOOKS AND PAMPHLETS RECEIVED.

A Text-Book of Pharmacology, Therapeutics, and Materia Medica. By T. Lander Brunton, M.D., D.S.C., F.R.S. Adapted to the United States Pharmacopoeia by Francis H. Williams, M.D., Boston, Mass. Philadelphia: Lea Brothers & Co., 1885.

## Original Articles.

SYPHILIS AND INSANITY.<sup>1</sup>

BY WM. B. GOLDSMITH, M.D.,

*Physician and Superintendent Danvers Lunatic Hospital.*

I DESIRE in this paper to call your attention cursorily to the manner in which syphilis acts as a cause of different forms of insanity, and more particularly to what appears to me a prevalent professional error as to the value of anti-syphilitic treatment in mental diseases.

For convenience, I will first enumerate the various forms of insanity which syphilis may cause in its so-called three stages.

*First.* Syphilis may, soon after infection, cause melancholia, and less frequently mania, by psychical influence alone without any influence of the specific virus.

It is needless to say much upon this point. All of you have probably seen cases in which, after recently contracted syphilis, remorse for the past and hopelessness and dread of the future have been the exciting causes of melancholia. It is also well known that the same causes which are frequently efficient in producing melancholia will sometimes produce mania, that is to say, a reasonable profound mental depression, when it causes insanity at all, will usually cause insane depression or melancholia, but exceptionally, will entirely change its form on passing the physiological limit and become mania.

*Second.* Melancholia, or great intellectual inactivity and incapacity—a temporary dementia—may occur at any time during secondary syphilis as a result of the cachexia of the disease, or of that and anti-syphilitic treatment together, for those accustomed to treat venereal disease recognize that one of the effects of mercurialization, in not a small number of cases, is profound mental depression associated with a great failure in intellectual activity and capacity, often resembling that occurring during convalescence from severe fevers, but sometimes, when the mercury has been pushed so far as to produce general or local tremor, simulating progressive paresis.

The melancholia occurring during either of these stages of the disease, and indeed the melancholia occurring in any stage of syphilis may take the form of the so-called syphiliphobia, which is really nothing more than an unusually well-defined and distressing form of hypochondria. Cases are also reported in which acute mania was thought to be due to an unusually marked febrile disturbance attending the outbreak of early secondary symptoms. As high temperature from various causes is known to cause maniacal symptoms in certain susceptible people, this does not seem improbable, though I have had no personal experience with such cases.

*Third.* Tertiary syphilis is, however, decidedly more important in its influence upon the nervous system, and may undoubtedly cause mental disease by producing changes in various portions of the encephalon which can be recognized as syphilitic after death—gummy tumors, pachymeningitis interna and externa, and syphilitic endarteritis. It is not necessary for me to describe the clinical history of these cases. They

present, in the main, the symptoms which non-syphilitic lesions of similar form and situation produce. That is, a syphilitic brain-tumor produces like paralysis and like psychical enfeeblement or irritation as a non-syphilitic one, and syphilitic disease of the meninges or arteries produces like symptoms as similar non-syphilitic disease of the same structures.

Positive mental symptoms, using the term to denote morbid excitement, delusions and hallucinations, are not often prominent in these cases and the negative symptoms, that is, various evidences of mental failure are almost invariably present and decided. With this dementia there are often physical symptoms very like those shown in parietic dementia, and it is probably these cases which Fournier, Voisin, Mickle, and others speak of as pseudo-general paresis, a class of cases which it is often impossible to differentiate from general paresis proper by personal examination alone, though prolonged observation or an accurate history usually discloses a lack of variety and completeness in the course of the disease, paralysis of small groups of muscles, etc., which are not likely to be found in progressive paresis. With these cases we are on pretty sure ground, there is the history of syphilis, and specific pathological changes to be found post-mortem.

Many observers, as Fournier, Voisin, and Mickle, believe also, that they can be diagnosed by a trial of anti-syphilitic treatment. My own experience has been less favorable so far as the mental symptoms are concerned, but there is still active syphilis and its vigorous treatment is indicated.

There are, too, a large number of patients with histories of preceding syphilis who have unmistakably both the bodily and mental symptoms of progressive paresis, but who show no evidence of active syphilis during life, and in whom no changes recognized by pathologists as syphilitic can be found post-mortem. The share to be assigned syphilis in their production can therefore only be determined by a totally different process of investigations; that is, the numerical, and from the study of the method of occurrence of certain individual cases.

This method presents several sources of fallacy, and its results can certainly only be considered conclusive after the findings of different men observing patients in different localities and conditions are grouped, and in accomplishing this grouping we must remember that—

*First.* Syphilis is a possession which no one cares to vaunt, and which is often concealed from all except the physician who treats it. The patient's insanity often makes his own statements unreliable, and, when this is not the case, he often lies about it.

*Second.* The disease varies greatly in prevalence in different localities and among different classes of people.

*Third.* The personal equation of the observer is an important factor, as some physicians are ready to take the history of any kind of a venereal sore, or almost any scar upon the body as evidence of previous constitutional infection. Thus, Stretch Dowse, for example, says<sup>2</sup> that he has had in his practice at the Central London Sick Asylum in seven years over 10,000 patients, and adds: "I have no hesitation in saying that three-fourths were more or less the subjects of acquired or congenital syphilis." By the numerical method it would be easy for Dr. Dowse to make syphilis the chief cause of any disease known to medicine.

<sup>1</sup> Read before the Association of Superintendents of American Institutions for the Insane, at the annual meeting at Saratoga, June 17, 1885.

<sup>2</sup> Syphilis of the brain and spinal cord. 1882, p. 1.

*Fourth.* The difficulty of tabulating results is increased by the tendency of many observers to diagnose as cerebral syphilis all cases supposed to be of syphilitic origin, though their symptoms are identical with those of progressive paresis.

Without attempting to give the findings of all who have recorded their observations, I will mention those which seem to me the most carefully taken and reliable, before contributing my own experience. Schuele found that about fifty per cent. of his paretics gave histories of syphilis, and thought it a prominent cause. Mendel found it in sixty per cent. of two hundred cases. Spitzka and Kiernan found it in about one-third of the cases at the New York City Asylum, though they thought it probably larger. Spitzka found the percentage of syphilis smaller among private patients.

Probably the most extended and carefully compared observations yet reported are those of Rohmell, given at the International Medical Congress at Copenhagen, last year. He says<sup>3</sup> that in the Asylum St. Hans, near Roeskilde, Denmark, there have been 317 cases of paresis during the past twenty years (269 men and 48 women), the total number of patients treated during this time being 1,729 men and 1,753 women. The proportion of paretics being thus: 1 to 6.5 among the men and 1 to 3.6 among the women, the women being as 1 to 3.6 more seldom than the men.

Of the 317 paretics, 289 or 77.2 per cent. had a history of syphilis, while of 1,000 other patients examined, only 72 or 7.2 per cent. had such a history. In typical cases of paresis, by which I suppose those with exalted delusions are meant, 82 per cent. gave a history of syphilis, in those with mental depression 78 per cent., and with dementia 76 per cent. Among the women the proportion was 78 per cent. The average period from infection was  $11\frac{1}{2}$  years, extremes 4 and 20 years, most frequent period 6 to 10 years. The syphilis had almost always been mild in character. Antisyphilitic treatment had never effected a cure. McDonald<sup>4</sup> believes that syphilis was the cause of paretics in the eighty per cent. of his cases, and cites two interesting facts.

1st. That during the eighty-three years existence of the York Retreat, which treats a large number of Quakers, whose purity of life is proverbial, only three cases of progressive paresis were encountered in persons of this sect.

2d. He noticed, when Superintendent of the Perth District Asylum, Scotland, that he had no paretics who had been continuously residents in the country, but that all were soldiers, or those who had been employed in large towns. And yet he says that illicit sexual intercourse and drunkenness were shockingly common in that region, so that the immunity could not be ascribed to the avoidance of excesses.

It is well known from others that progressive paresis is rare among the highland Scotch, but frequent in the cities. It is also well known that there are strikingly few paretics in Ireland, and I have been told by a medical man, who had large experience in Ireland, that the amount of syphilis is also recognized to be very small there. This infrequency in syphilis in Ireland was also, I remember, referred to as a fact in a discussion of the British Medical Association a few

years ago, but I have no statistics at my command to prove it, neither have I any reliable statistics to offer as to the frequency of paresis where syphilis is known to be especially prevalent, as at Naples. In general, both can be said to be urban diseases.

The results of my own experience are as follows:

Among 126 male and 28 female paretics treated at the Danvers Lunatic Hospital since I have been Physician and Superintendent there, 36 men and 11 women are known to have had syphilis, or nearly one-third of the whole number. I may say, incidentally, that 32 of these 154 cases were Irish, which shows that their comparative immunity from the disease does not persist in this country, though their proportion to the whole number of paretics is somewhat smaller than it is in the entire hospital population.

These statistics unquestionably show very much less syphilis than actually existed, as we often fail to obtain any accurate history in this particular from patients of the class which constitute the greater part of the population at Danvers, and I have been careful to include only those in whom the evidence of this disease was fairly convincing. In five hundred other patients taken consecutively from the same record books, paretics being excluded, syphilis was found to be more than six times less frequent.

I may also say, that in my experience as an Assistant Physician at the Bloomingdale Asylum, New York City, where it was possible, because of the class of patients, to obtain much more accurate histories than at Danvers, I was impressed by the frequency of syphilis among the progressive paretics in spite of the fact that they belonged to a higher class socially, where the general percentage of syphilis is probably not so large, but this is merely my remembrance, as I have no record of these cases.

Progressive paresis has also occurred in two families under my observation in such manner as to be more easily explained by a syphilitic origin than as a coincidence. In the first, a man and his wife of respectable social standing, were both syphilitic and both had progressive paresis eight or ten years later.

In the second, a man had syphilis and communicated it to his wife. A sister of the wife, sixteen years old, who was resident in the family, also contracted syphilis—the primary sore not being on the genitals, as their family physician informed me. The man had progressive paresis six years after the syphilitic infection, the wife eight years after, and the sister seven years after, or when she was but twenty-three years old.

It is also possible to judge of the probability of the syphilitic cachexia producing this form of brain disease from analogy. Locomotor ataxia, as is well known, has several points of resemblance to progressive paresis in its method of occurrence. Both diseases seldom attack the very old or young, but take those in the prime of life. The proportionate preponderance of men over women in those affected is about the same in both, and in both an hereditary neurotic tendency is less frequent than in most other forms of psychical or nervous diseases. It has also been noted in both diseases that the syphilis has usually been mild and has preceded the nervous affection by several years.

In locomotor ataxia, a more satisfactory conclusion as to the frequency of antecedent syphilis can be arrived at because of the mental integrity of the patients, and various observers have found it to exist in a large proportion of cases.

<sup>3</sup> Rohmell-Ueber die Rolle der Syphilis bei der allgemeinen fortschreitenden Paralyse, Central-Blatt für Nervenkranke, Psychiatrie, etc.

<sup>4</sup> Journal Mental Science, Vol. 20, page 167.

Erb<sup>5</sup> finds 80 per cent. of his 200 tabetic patients to have had syphilis, while this was the case with only 23 per cent. of 1,500 other patients who attended his clinic. Fournier thinks it is present in 93 per cent., Voigt in 81 per cent., and Seguin<sup>6</sup> finds it in over 50 per cent.

I think it can be fairly claimed that the unusual frequency of a syphilitic history among progressive paresis, the great comparative infrequency of progressive paresis in certain regions where syphilis is not prevalent, though the statistics are not sufficiently accurate to give this argument great weight, the exceptional instances in which progressive paresis apparently follows the syphilis communicated from one person to another, and the inferences drawn from its analogy with locomotor ataxia, make it in the highest degree probable that syphilis is the most prominent factor in the etiology of progressive paresis.

And though I cannot say, as Erb does, of *tabes dorsalis*, that the man who has never had syphilis need not fear progressive paresis, it is my belief that he enjoys three times better chance of immunity than the one who has suffered from it.

Not in that the nervous disease is a part of the syphilitic process, as a gummy tumor is, but in that syphilis, having passed through all its stages and possibly having become entirely extinct, leaves the nervous centres prone to take on the new pathological process, the nervous disease finding a congenial habitat in the region devastated by previous syphilis. I think this in spite of the observations of Fournier and others that it is the untreated or inadequately treated syphilis which is followed by nervous disease, as it seems no less reasonable to suppose that the unchecked primary disease works greater devastation and is therefore more likely to be followed by nervous degeneration than to consider the secondary disease proof of the continued activity of the specific poison.

If it is a fact that progressive paresis follows syphilis as a result and in no sense as a symptom of the disease, it would have an important bearing upon therapeutic treatment, and it is concerning this that I especially desire to hear the opinions of the members of this association.

General medical text books and college lecturers with great unanimity claim that there is a vast amount of insanity due to tertiary syphilis, which only needs the iodide of potassium for its alleviation. This is fairly shown in a lecture by Prof. H. R. Wood, reported in the BOSTON MEDICAL AND SURGICAL JOURNAL, January 10, 1881.

He speaks of cases that cannot be distinguished from paresis and says, "formerly when I took charge of a case of specific disease of the brain (and he evidently considers antecedent syphilis presumptive proof then that brain disease is specific), I always gave a favorable prognosis, but experience has shown me that sometimes such prognoses are not realized," and again, "the fact that insanity, palsy or headache have a syphilitic origin makes them much more amenable to treatment than if they were due to other causes."

Kiernan<sup>7</sup> says the value of anti-syphilitic treatment in progressive paresis will depend upon the stage at which the syphilis is found, and in no case is it contraindicated.

Having started hospital practice with this belief and

<sup>5</sup> American Journal Medical Sciences, January, 1881.

<sup>6</sup> Archives Medicales, August, 1881.

<sup>7</sup> Attend and Neurologist, July, 1882.

having given a very large amount of anti-syphilitic remedies, my experience makes me decidedly less hopeful. I am forced to say that I have never seen a case in which I believe that *positive* symptoms of insanity, occurring after syphilis had reached the tertiary stage, were removed or alleviated by anti-syphilitic treatment.

Therefore, when a patient with symptoms indicating progressive paresis has a history of previous syphilis, I think he is more likely to have paresis without being more likely to recover from it; and in my experience, active treatment by mercury or iodide of potassium usually has a debilitating and injurious effect. The same is true of all forms of mental disease which are not preceded by severe headaches, paralysis of limited groups of muscles, or localized disorder of sensation, that is, by symptoms indicating a circumscribed new growth. When such symptoms exist, the frequent efficacy of adequate anti-syphilitic treatment is unquestionable, and I have no doubt that mental disease can be averted by its employment.

I may add also, that in a recent trip abroad, I took occasion to inquire the experience of some of the best authorities<sup>8</sup> in England, France and Germany, and was somewhat surprised to see the unanimity with which they said that they had ceased to expect cure of mental symptoms through anti-syphilitic treatment. Among those whom I have consulted in this country, however, I have found much difference of opinion.

## A CASE OF PSEUDO-HYPERTROPHIC MUSCULAR PARALYSIS.<sup>1</sup>

BY PHILIP COMBES KNAPP, A.M., M.D., HARVARD.

Assistant Physician to Out-Patients with Disorders of the Nervous System, Boston City Hospital.

THE patient, a boy of six, was born in Boston, of German parentage. He was sent to the Boston City Hospital, September 21st, by Dr. Broughton, of Jamaica Plain, from whom, and from the boy's parents, the following history was obtained.

**FAMILY HISTORY:** A full history of his father's family was not obtained; on his mother's side two cases of phthisis were reported, but no evidence of any neurotic history could be obtained. His parents are healthy. He himself is the youngest of eight living children, the rest of whom are well. Four other children died in infancy of "water on the brain," one also having cholera infantum.

**PREVIOUS HISTORY:** The patient was a very feeble child, too weak to nurse, and had to be brought up on the bottle. During his first year he had diarrhoea much of the time, and seemed very delicate. When he was a year old, he had whooping-cough, attended with severe and frequent convulsions; he had convulsions at intervals for two months, once having seven in one night. After that he recovered, grew stronger, and has seemed healthy ever since, except for his present trouble, and for an illness of two days when he was two years old, "which seemed like water on the brain." When he began to walk, it was noticed that his left leg gave out at times, and he would sometimes fall. His legs were very fat, much fatter proportion

<sup>1</sup> Read before the section for Clinical Medicine, Pathology, and Hygiene of the Suffolk District Medical Society, October 11, 1885.

<sup>8</sup> In reading this paper I used the names of some of the foreign physicians consulted, but it has seemed to me unwise, without permission, to make them responsible for an opinion or part of which they might choose to express in some other form, and I so discreetly omitted the names in preparing the paper for printing. W. B. C.

ally than his thighs, but at present his mother thinks the contrast is not so marked.

About a year ago, without any signs of illness, his parents noticed that he had more difficulty in walking. The trouble came on very slowly and gradually. He could not walk as well, and when out with other children it was noticed that he could not run, and that a very slight push would knock him down. If he walked much he had a tired feeling in his legs, but he never had any pains in them, nor any peculiar sensations. The family for some time have laughed at him for "sticking his belly out" as he walks and stands. He has not been able to go up stairs well; when he does so, he pulls himself up by the banisters or takes hold of his knees, having much difficulty in getting up. He puts the left foot first, they say, in going up stairs, and the right in coming down, the right leg seeming weaker. He never has headache, and sleeps well nights. He is quick-witted, good-natured and always happy; he answers questions readily, without any impairment of articulation, and seems more than ordinarily intelligent. He has not been to school yet, partly from his difficulty in locomotion, and partly for fear that the larger boys will knock him down and hurt him. He has never had any serious cough, nor any dyspnea or palpitation. He has a good appetite, eats everything, and has no trouble from indigestion; his bowels are regular. He has no difficulty with micturition.

**PRESENT CONDITION.**—The child is of medium size, fairly developed, not very well nourished. The skin is pale and translucent, the subcutaneous veins are quite apparent. There is no eruption or marbling of the skin. The head is rather large and square. The pupils are of medium size and react well to light; the eyes were examined by Dr. Wadsworth and the discs were pronounced normal. The eyes, face, lips and tongue move naturally. The tongue was clean. Examination of the chest was negative. There was no impairment of tactile sensation. There were no signs of vaso-motor disturbance in the skin, which showed no special differences of temperature to the hand in various parts. There was no ataxia in the movements of the hands. The patellar reflex was absent, and there was no ankle clonus; plantar, abdominal, and epigastric reflexes present. No tenderness over the spine or nerve-trunks.

There was no very great hypertrophy of any group of muscles. The facial muscles showed no marked atrophy or enlargement, and he could move them without difficulty; the expression of the face, however, was very peculiar, the eyebrows were elevated, the eyes staring and prominent, the mouth often a little open, the lines of the face were not marked, and there was but little play of expression. His father, however, had noticed no change in this respect. The muscular development of the upper part of the body was rather poor. The arms were small, but there was no atrophy or hypertrophy that would strike the eye. The latissimus dorsi and pectorals were poorly developed, yet corresponded fairly to the other muscles. The infraspinatus muscle filled the infra-spinous to a completely, but did not feel hard. The deltoid felt rather firm, than some of the other muscles, the triceps was of good size and decidedly harder than the biceps, the muscles of the forearm were also firm. There was no atrophy of the thenar muscles. The glutei were unduly prominent. The thighs were

small, the quadriceps felt flabby. The calves were large and very hard and firm. Although the calves were not unduly enlarged for a healthy boy of his years, they were much enlarged in proportion to the other muscles. Circumference of the thigh in the largest part, 10 inches, of the calves, 8½ inches.

The child stands with his feet well apart, his shoulders back, his abdomen very prominent, his arms semi-flexed, abducted, and carried a little backward. His scapula stand out in a wing-like fashion from the chest wall. A plumb-line dropped from the spinous processes between the scapulae, clears the sacrum, but not the buttocks, as he stands erect. His gait is decidedly waddling, especially when he runs. His grasp is not very strong, but it is fair for his years. His arms show no special loss of strength. When he stoops over to pick up anything, he has much difficulty in straightening up again, and usually helps himself by putting his hands on his knees and throwing his body back, although he does not climb up his thighs much. When he is put on his back and told to get up, he first rolls over on his belly, then he lifts himself up on his hands, straightens his legs, walks up to his hands, then he gets hold of his knees, pushes himself up, and throws his body back in precisely the manner depicted by Gowers. He cannot bend his knees and rise up again, and, if he stands on one leg and a forcible attempt is made to bend the knee, he goes down in a heap. He also goes down suddenly when he attempts to sit. His favorite way of going up stairs is to creep up on his hands and knees; if told to walk up, he prefers to get hold of the banisters and pull himself along. If made to go up without taking hold of anything, he has very great difficulty, even with stairs of a very slight rise, and sometimes he requires help. He always puts his left foot up first and pushes himself up by his knees. If told to put the right foot first, he has much more difficulty, and often fails entirely to get up. He can rise up on his toes very well, even on one foot, and he can bring his heels squarely to the ground. Dorsal flexion of the foot is not quite so complete as normal, but it is impossible to say whether it is due to a weakness of the flexor groups or to a slight contraction of the gastrocnemii.

An electrical examination was made by the induced current, but it caused so much pain that a complete and careful examination was not made. The deltoid, biceps and extensors of the arm react feebly to a tolerably strong current. The gastrocnemii and glutei react to a painful current, the full strength of a Fleming and Talbot battery, freshly filled. The tibialis anticus reacts very little, if at all, but the pain of the application made the child so restless that it was impossible to observe the reaction carefully. The quadriceps showed absolutely no reaction to the strongest current.

The boy has been given cod liver oil and syrup of the iodide of iron, and directed to come to the outpatient department three times a week to have faradism applied.

—A new journal, called *The Medical Press* of western New York has appeared in its first issue. It is published at Buffalo, and has a large number of stockholders among the resident medical profession. It is edited by Dr. Roswell Park.

A CASE OF TUBERCULOSIS OF THE IRIS.<sup>1</sup>

BY MYLES STANDISH, M.D., OF BOSTON.

D. A., a girl fourteen years of age, was first seen by me on the 22d of May, 1885, when I obtained the following family history. Her father was a man of good health, and had never acquired syphilis, but had used alcohol to excess. Her mother was a healthy, well-nourished woman, and had borne four children, of whom our patient was the eldest. All the children are living, but are somewhat pale and delicate looking, and rather small for their ages. The mother had never had any miscarriages. Neither the mother nor our patient, nor either of her brothers or her sister, ever had any eruption upon the body, any continued sore throat, swollen glands, or any purulent discharge from the ears.

Our patient is small in stature, pale and anæmic, and although her menses have been established for a year, has a peculiarly slight and girlish form. There is nothing in the configuration of the shape of the head or teeth to indicate inherited specific disease. She has always been considered well until the summer of 1884, when she had an attack described as nervous prostration. She attended school, however, in the autumn for two months, when in the last week of November she was taken ill with the following symptoms: pain about the waist, with much distress for breath and an inability to lie down. Ascites soon developed, with severe epigastric pain, nausea and vomiting; there was no jaundice, no evidence of disease of the kidneys, no evidence of any lesion of the lungs, no general tenderness of the abdomen, and no diarrhoea. The diagnosis of her family physician was acute hepatitis. All of the above history was confirmed by this gentleman, who is a skilful physician and accurate observer.

The patient recovered slowly, but in three months' time had recovered her color and accustomed weight, her menses had returned and she was considered quite well.

Four weeks before I first saw her, our patient began to complain of feeling tired and a general feeling of malaise, and about the same time her right eye began to trouble her, with no history of an injury; it became red and the sight gradually became dim, but as she did not complain of much pain the mother supposed it, as she said, to be a cold in the eye, and neglected to apply for advice. Upon discovering, however, that the eye was quite blind she immediately brought her for treatment.

Upon examination, the condition of the eye was found as follows: The conjunctiva somewhat hyperæmic in certain areas near the sclero-corneal margin; the cornea was somewhat hazy, with several deposits on the membrane of Descemet; the iris firmly attached throughout its entire pupillary margin to the capsule of the lens. The pupil blocked by lymph. The iris was not congested, but in general had a somewhat atrophic appearance.

Above the pupil and springing from the iris near its ciliary border was a rounded protuberant growth two millimetres in diameter and projecting from the plane of the iris to an estimated height of one millimetre. This growth was broader at the top than at its base, and of a yellowish color slightly tinged with pink. Over the surface of the tumor coursed several small

vessels. No view could be had of the fundus. An attempt was made to dilate the pupil by the repeated use of a one per cent. solution of atropine during several days; this failing, cocaine and duboisia were used separately and together, all with no effect. V. O. D =  $\frac{2}{5}$ .

The case was watched for four weeks, in which time the growth slowly increased to double its size when first seen. A one per cent. solution of atropine was used during this period. This growth of the tumor was unaccompanied by pain, and the conjunctiva became white, presenting only a few enlarged vessels. Vision became reduced to the perception of shadows.

Dr. Wadsworth then saw the case with me in consultation. At this time the eye had not been examined by me for a week, and three new growths, a millimetre in diameter or less, were found springing from the iris at other points near the ciliary margin of the iris. These new growths were not accompanied by any access of pain or congestion of the iris, and by only very slight injection of conjunctiva. Dr. Wadsworth agreeing with me in my diagnosis of tubercle, enucleation was advised. I enucleated the eye on the 20th of June at the Massachusetts General Hospital.

The patient made a rapid recovery, and now appears in much better condition as to general health.

Upon examination of the eye microscopically after removal, the vitreous body was found to be normal, the retina and choroid in apposition to the sclera and normal in appearance, the ciliary body of normal size and not involved in the pathological change, the lens substance somewhat opaque. The iris was attached to the capsule of the lens very firmly throughout the entire circuit of its pupillary margin, and also beneath the entire area of the base of the principal growth. This growth sprang from the iris near its ciliary margin. The base of the growth was two and five-tenths millimetres in diameter, and rose from the plane of the iris two millimetres, when, coming in contact with the cornea, it was spread out, conforming to the curve of the inner surface of the cornea, to a width of four millimetres. It was non-pigmented.

The growth was given to Dr. Harold C. Ernst for examination, and he makes the following report:—

The Warren Anatomical Museum. New growth submitted for analysis July 9, 1885.

A tumor two or three millimetres in diameter lying anterior to the iris and connected with it. The specimen had been previously hardened in Muller's fluid, thus rendering it impossible to speak of its fresh appearance. Having been washed for thirty-six hours in distilled water, the specimen was re-hardened in absolute alcohol, sections made and placed under the microscope. Thus the growth was seen to come from the iris, this side of it being well supplied with vessels. Farther out from the point of attachment the tissue was made up of granulation, with a number of giant cells. No cheesy degeneration was present. Sections stained after Koch's modification of Ehrlich's method showed the presence of a few bacilli of tuberculosis. The first treatment of these specimens rendered the detection of these organisms more than usually difficult.

*Diagnosis.* Tuberculosis of the iris.

— A case of small pox has appeared at Newport, R. I., in the person of the matron of the Newport Hospital.

## REPORT ON DERMATOLOGY.

BY GEORGE H. TILDEN, M.D.

ORIGIN OF THE PIGMENTATION OF THE SKIN IN ADDISON'S DISEASE.<sup>1</sup>

THE following conclusions with regard to the hypertrophy of the cutaneous pigment in cases of Addison's disease are given by Nothnagel as the result of a careful study of the subject.

In Addison's disease there is not only pigmentation of the rete malpighi, but there are also a greater or less number of pigment cells to be found in the corium, which pigment cells are seen to be in intimate connection with the blood vessels. Precisely similar conditions are found to exist in the normal and localized increase of cutaneous pigment in the white races, such as that of the serotum, etc., in the skin of the negro, in the increased pigmentation of the linea alba in cases of pregnancy, and in the discoloration of the skin sometimes seen in connection with phthisis; and it is proper, therefore, to assume that the conditions of its hypertrophy are the same in cases of Addison's disease as in these other instances of increased pigmentation of the skin. The pigment present in these cases is not formed in the cells of the rete malpighi by metabolic activity of their protoplasm, but is transferred to them from the corium by pigment-carrying cells, which do not manufacture the pigment they contain, but abstract it in some manner from the blood. The conditions which favor the formation of pigment in the instances of normal increase of the same, are inherent and physiological peculiarities of tissue, but in the cases of pathological hypertrophy of pigment, these conditions are probably in some way under the influence of the nervous system.

Richl,<sup>2</sup> at a meeting of the Royal Association of Physicians, in Vienna, announced as the result of the study of four cases of Addison's disease, in the laboratory of Prof. Kundrat, that he was able to confirm the conclusions reached by Nothnagel in his investigations. He had made microscopic examination of the skin in these cases and had found the adventitia of the cutaneous blood vessels to be infiltrated with cellular elements, which infiltration existed not only in the pigmented regions of skin, but also in regions which were normal as regards color. In the smaller arteries of the skin, the media was found to be swollen and obscurely pigmented. In three of the cases of Addison's disease which had been under investigation, there existed in the smaller arteries also, thrombi which filled them either partially or entirely. Since the above changes in the walls of the blood vessels were to be detected throughout the whole skin, in non-pigmented as well as in pigmented regions, also in the subcutaneous tissues and in various membranes and organs of the body, such as the pleura, peritoneum and liver; while the thrombi above-mentioned, existed only in the blood vessels of the skin and of the capsule of the suprarenal bodies, the speaker was of the opinion that general pathological changes in the blood vessels was the primary condition, and that to this was due the exit of pigment from the blood, giving rise to the pigmentation peculiar to Addison's disease.

RECOVERY FROM LEPROA TUBEROSA.<sup>3</sup>

At the fourth meeting of the German Medical Con-

*Zeitschrift für Klin. Med.*, Band LX, Heft 3, u. 4, S. 165.

*Wiener Med. Press.*, No. 2, p. 20.

*Allgemeine Med. Central. Zeitung*, No. 16, p. 260.

gress, held at Wiesbaden, in April, 1885, Unna reported a case of recovery from leprosy. The patient was of German birth, a woman thirty-eight years of age, who had acquired the disease two years previously in Brazil, of which country she had been an inhabitant for fifteen years. The manifestations of the disease were of more than average severity and represented the tuberculous form of the affection, the cutaneous lesions being most numerous upon the face, arms and legs, and unattended by anesthesia or mutilation. After four months of treatment, which consisted in the external application for various periods of time, of salves and plasters containing various proportions of crysarobin, pyrogallie acid, resorcin, and suephoichthyolate of ammonium, and the continuous internal administration of one gramme a day, of the last-mentioned drug, the patient was reported as cured.

Bacz, of Tokio, who was present, congratulated Unna upon the happy results of his therapeutic endeavors, and regretted to state that he himself had never been so fortunate. He had generally failed to give any relief whatever, only occasionally had he seen any improvement follow treatment of leprosy, and in no case had he witnessed a cure of the disease. He considered the best method of treatment to be the internal administration of large doses of oleum gynocardiae, which sometimes seemed to cause a diminution in the size of the tubercles and in their red color. In the city of Tokio, there was a family who made a specialty of the treatment of leprosy, and who had often attained remarkably good results by giving the above-mentioned oil, in what was supposed to be a peculiar preparation, and by using a restricted diet and hot baths. The speaker advised great caution in making the diagnosis of complete cure of leprosy, as the slighter manifestations of the disease are often very difficult of recognition, trivial hyperæmia and doubtful dullness of sensation being often for a long time the only symptoms.

He also made some remarks concerning the contagiousness of leprosy. Since the discovery of a bacillus peculiar to the disease, there has been a marked tendency among physicians to regard the affection as contagious. The speaker would not positively deny the possibility of contagion, and admitted that under conditions of long continued and intimate connection, such as were furnished by the married state, the disease might be transmitted, but nevertheless, he considered the tendency of leprosy to be transmitted by contagion as very slight. He had for eight years had cases of leprosy under his charge and never isolated them, but placed them indiscriminately amongst other patients. Many cases of leprosy had been for years in the hospital, and no instance of the disease had occurred in physicians, nurses, or other patients. In one of the hospitals in Tokio which is crowded with cases of leprosy, there has never been seen an instance of transmission of the disease by contagion, and the specialist mentioned above, whose family for three generations had been continually in relations with the mahaly, was of the same opinion. Careful inquiry also among the physicians in Japan, outside of Tokio, failed to elicit any testimony in favor of the eminent contagiousness of leprosy. The speaker, therefore, was of the opinion that the disease is at the most, no more contagious than syphilis, and probably much less so, and that at all events, there was no danger of contagion in the ordinary conditions of daily life, and that so long as individuals suffering from syphilis and tuberculosis were

not banished from society, there was no just ground for subjecting lepers to seclusion.

#### TUBERCULOUS MENINGITIS FOLLOWING LUPUS.<sup>4</sup>

Doutrelepoint publishes the case of a badly-nourished anæmic girl, eighteen years of age, who suffered from lupus of the face. The bacilli of tuberculosis were detected in scrapings from the granulation tissue present and in a bit of diseased skin which had been excised for purposes of examination. Marked improvement in the general condition of the patient and cicatrization of the cutaneous lesions followed the internal administration of arsenic and iron, and local treatment, which consisted in scraping the diseased regions of skin with a sharp spoon and the subsequent application of a solution of corrosive sublimate. Shortly afterward the disease recurred in the left cheek, its reappearance being accompanied by pain in the lower part of the chest, headache, vomiting and fever. Microscopic examination of the blood showed the presence therein of the bacilli of tuberculosis, and death ensued with the development of comatose symptoms. The autopsy showed tuberculous meningitis, collections of fresh tubercles in the lower lobes of both lungs and several tuberculous ulcerations in the intestine. All these lesions were of recent formation, and it is probable that the preëxisting tuberculous disease of the skin (lupus) gave rise to further infection of the system.

#### ETIOLOGY OF PURPURA HÆMORRHAGICA FERRILIS.<sup>5</sup>

During the past few years there has been a disposition on the part of certain observers, amongst them Klebs and v. Rittersheim, to regard purpura hæmorrhagica as an infectious disease. Petrone<sup>6</sup> made microscopic examination of the blood taken from two well-marked cases of purpura hæmorrhagica, in which there were also hæmorrhages from the mucous membranes of the mouth, rectum, nose and urinary tract, but without any scorbutic manifestations in the mouth. He detected the presence in the blood from each case, of small micrococci and partly isolated, partly grouped bacilli. Inoculation of rabbits with the blood from each of these cases was followed by a positive result, in the shape of the production of hæmorrhages in the dura mater, serous membranes, subcutaneous connective tissues and muscles and in the blood of the inoculated animals were to be found the same micrococci together with some bacteria (sic). Inoculation also of a healthy rabbit, with blood taken from the inoculated rabbits was followed by similar results.

The following fatal case of purpura hæmorrhagica came under observation in the medical clinic of Professor Quinke at Kiel, and is reported by his first assistant, Reher. The patient, a boy of eight years, was suddenly attacked by headache, loss of appetite, and vomiting, and two days afterward ensued sore throat and difficulty in swallowing. Five days after the beginning of the affection the boy was brought to the hospital, the chief symptoms complained of, being shortness of breath, painful deglutition, and debility. The body was found to be covered with bluish-black or blood red spots, varying in size from that of a pin's head to that of a split pea (hæmorrhagic macula), which were most numerous upon the neck and extremities, less so upon the head and trunk. Both tonsils, more especially the right, were very much enlarged, so

much so as to touch one another, the surfaces which were in contact being covered with a thin blackish green film of necrotic tissue. The uvula also, which was caught between the tonsils was much swollen and covered with a grayish film. By reason of this increase in size of the tonsils, the fauces were completely blocked and the posterior wall of the pharynx was inaccessible both to ocular and tactile inspection. The submaxillary and anterior cervical lymphatic glands, especially those on the right side were enlarged and painful. Examination of the thoracic and abdominal cavities showed slight bronchitis, rapidity of the heart's action without murmur, and considerable increase in the size of the spleen. The amount of urine was small but it contained no albumen. There was constipation, loss of appetite, coated tongue, and a temperature of from 39° to 40° C. The tonsils showed a tendency to bleed upon slight irritation and shreds and lumps of necrotic tissue and of a peculiar jelly-like substance, apparently derived from the tonsils, were repeatedly removed from the throat by gargling and the help of the fingers. With continuation of the high temperature, fresh hæmorrhagic deposits manifested themselves in the skin, there also ensued exudation of fluid in the serous cavities of the body, the debility and the cyanosis (from asphyxia) rapidly increased, and death took place ten days after the beginning of the disease.

The autopsy was made twelve to sixteen hours after death, and there was found extensive gangrenous destruction of the tonsils and the mucous membrane of the pharynx and the beginning of a similar process in the gums. There were numerous hæmorrhages in the skin, pleura, lungs, endocardium, pericardium, heart, mucous membrane and walls of the oesophagus, diaphragm, liver, kidneys and renal capsules, mucous membrane of the bladder, testicles, mucous membrane of the stomach, and in the large intestine. There were also found a few hæmorrhagic spots in the meninges of the brain, hydrocephalus internus, and fresh pachymeningitis. There existed some thickening of the mitral valve, cloudy swelling of the liver and kidneys, enormous increase in the size of the spleen, moderate swelling of the intestinal follicles, enlargement of the bronchial, mesenteric and retro-peritoneal lymphatic glands and exudation of fluid into the serous cavities of the body.

The clinical course of the affection and the post-mortem appearances in this case, both clearly indicate its infectious nature, and in the blood of the cadaver were detected by microscopic examination small, round cocci arranged in longer or shorter chains (streptococci). They were smaller in size than the cocci peculiar to osteomyelitis, and their disposition in chains was similar to that assumed by the cocci of diphtheritic membranes, when cultivated in gelatine.

Similar micrococci were found in microscopic sections of the various organs of the body, as a rule collected in masses which obliterated the calibre of the capillaries and smaller bloodvessels, this being the case more especially in the kidneys, the cervical lymphatic glands and the spleen and most of all in the liver. Other kinds of microorganisms were not to be detected in the blood or in the tissues of the body. It was impossible to demonstrate with entire satisfaction the existence of these micrococci in microscopic sections of the skin, since the large number of "Mastzellen" present, furnished abundant sources of error, and because the amount of skin reserved for examination

<sup>4</sup> Deutsche Med. Wochenschrift, No. 7, 1886.

<sup>5</sup> Archiv für Exp. Path. u. Pharm., Band xix., Heft 6, p. 415.

<sup>6</sup> Chirz. degli ospitali., Nov. 7, 11 and 17, 1884.

was small. The extensive gangrenous destruction of the tonsils prevented any microscopic examination of those organs.

Inoculations of these micrococci were made upon gelatine and in from one to two days numerous spherical, non-coalescent colonies of micrococci, of a grayish color, were to be seen at each point of inoculation. Both microscopic examination of these colonies and their gross appearances and behavior under cultivation showed that they were all composed of the same kind of microorganism, without the admixture of any other kind of bacteria or of foreign material, while the microscope also demonstrated their identity with the micrococci which had been found in the blood and various organs of the body. Subcutaneous inoculation of two mice with these cultivated microorganisms, however, was followed by a negative result in each instance.

In the opinion of the writer, the extensive distribution of these micrococci throughout the body renders it probable that they were connected with the disease and it is not improbable that the numerous hemorrhages were caused by embolism of the smaller bloodvessels due to masses of microorganisms. Whether the consequent hemorrhages were caused by mechanical plugging of the bloodvessels alone, or whether the growth of the micrococci "in loco" or possibly chemical changes set up in the neighboring tissues, by their presence, had anything to do with the production of these hemorrhages is of course entirely a matter of speculation. The supposition that the presence of these micrococci in question was accidental or that they were the product of post-mortem changes, is considered by the writer to be untenable, for the reason that he has never been able to detect the same coccus in a very large number of inoculations made upon gelatine with the fluids of the body both before and after decomposition had taken place.

#### ACUTE ANGIO-NEUROTIC OEDEMA.<sup>6</sup>

After recapitulating Quinke's article on "Acute Circumscribed Oedema of the Skin,"<sup>7</sup> the author, P. Struening, remarks that slight cases of this affection are not very uncommon. In such cases, there occurs generally, circumscribed oedema of the skin of the face, notably of the eyelids, cheeks, and lips, without, however, affecting the mucous membranes of the throat and larynx, or there takes place oedema of the extremities without effusion into the cavities of the joints. The swelling in these cases is slight in amount, and they offer a marked contrast to the much rarer and severe forms of the affection, where the manifestations are often so violent and acute as to give rise to much discomfort and alarm. He gives the records of three cases of this severe variety of the malady, which came under his observation.

The first case was that of a man seventy years of age, who was perfectly well up to his twenty-fifth year. At that time, after "catching cold," he was suddenly affected with pain in swallowing, which symptom rapidly increased in severity, and in the course of one or two hours, reached a high grade of intensity. To this there was soon added hoarseness and difficulty in breathing, and this latter symptom increased to such an extent that suffocation seemed to be imminent. After these distressing symptoms had lasted for about

half an hour, their severity gradually abated, and during the course of the night they entirely disappeared, the patient being in his usual condition the following morning. Then there developed swelling of the under lip, and after this had lasted for several hours, there followed in succession swelling of the upper lip; cheeks and eyelids, giving rise to great disfigurement of the countenance. These phenomena remained in the stage of their greatest intensity for several hours, and then gradually disappeared, and in about three days the skin had returned to its normal condition. The patient remained for a long time free from any repetition of this attack, but at the same time he noticed that any ordinary injury was followed by notable swelling of the injured part, to a much greater extent than usual. During after years, the oedema of the skin and of the mucous membranes of the pharynx and larynx occasionally recurred, but with long interval of time between the attacks.

As a rule, the oedema appeared first in the face, one-half of the forehead or one cheek being first affected, and afterward the other side of the face, the eyelids and the lips. The oedema then advancing to the skin of the neck, there would be simultaneously developed difficulty of swallowing and of breathing. The latter symptom was occasionally so severe as to apparently threaten immediate suffocation. Sometimes the sequence of phenomena was reversed, the attack beginning with symptoms indicating obstruction of respiration, followed by oedema of the face. On several occasions there also ensued oedema of the penis and serotum. The slight attacks lasted from one to two days, and the more severe ones from three to four days, and occasionally these attacks were apparently induced by injury.

The patient also, not uncommonly, suffered from oedema of the upper and lower extremities, particularly after slight injury to the parts, and lasting for several hours. Even at his advanced age, the patient was subject to these attacks of oedema, and one especially which came on after he had been free from any symptoms of laryngeal stenosis for five years, was of such intensity that preparations were made to perform tracheotomy in order to relieve impending suffocation, but fortunately, at the last moment the symptoms began to abate and the operation was not needed. This attack lasted for four days and ended with the appearance of oedematous swelling of the lips, eyelids, cheeks and forehead, and finally, also, of the penis and serotum. During the time that there was oedema of the pharynx and larynx, profuse secretion of mucous and saliva took place. The oedematous regions of skin were not sensitive to pressure and gave rise merely to an unpleasant subjective feeling of tension. In color, they differed from normal skin only in being somewhat paler and more translucent in appearance. They were not sharply defined, but were gradually lost in the surrounding skin.

Much more common, however, than the oedematous manifestations mentioned above, were periodical attacks of violent vomiting, which had affected the patient every four or six weeks, ever since his twenty-sixth year. Often these attacks occurred without any apparent exciting cause, but sometimes they seemed to be due to indigestion, physical exertion, or "catching cold." The patient was generally warned of the approach of these attacks of vomiting by the appearance several hours beforehand of slight pain in the abdomen,

<sup>6</sup> *Zeitschrift für Klin. Med.* 1885, Band IX, H. II (5, p. 281).  
<sup>7</sup> *Arch. Derm. report in this Journal for Oct. 5th, 1882.*

which gradually increased in severity and was finally followed by vomiting, more or less severe and long continued. During an attack of this kind, there was a general collapsed condition of the abdominal walls, with the exception of the epigastrium, which was usually slightly protuberant, especially at the beginning of an attack. Slight attacks lasted from three to four hours, but the severe ones were of much longer duration, lasting twenty-four hours or more, during which time vomiting would occur from twenty to thirty times, the patient being able to retain nothing on his stomach, while the pain in the abdomen sometimes became very severe. There was generally manifest a certain dullness of the senses, great thirst, and a feeling of fatigue during these attacks. Afterward, the patient generally fell into a deep sleep from which he awoke in good condition, with the exception of a slight and temporary feeling of weakness, which lasted but a short time. The general health and condition of the patient was good, in spite of his having for more than forty years suffered from these repeated and severe attacks of vomiting.

The only surviving child of the patient, a boy sixteen years of age, strongly built and offering every appearance of health, also suffered from the same disease, which manifested itself in almost exactly the same way as in his father's case, and since his third year he had suffered from similar periodic attacks of vomiting, followed by sleep and recovery. One other child of the patient, a girl, had also been affected with the same malady.

The third case was that of a young woman, anæmic and of delicate build, who in her fifteenth year, after she had been subjected to a strong emotional shock, was suddenly attacked with nausea and vomiting, which lasted for several hours. Nothing of the kind occurred again until her twenty-second year, when again, after psychical disturbance there ensued another attack of vomiting. Since the occurrence of this second attack, she had suffered from similar attacks every fourteen days, which began with nausea, followed by vomiting and pain in the abdomen. She also suffered from chronic perimetritis, the exacerbations of which disease before and during the catamenia, seemed to predispose the patient to attacks of vomiting. Five years before, and again within a year, there had developed marked œdema of the eyelids which lasted for several days. Examination showed the internal organs with the exception of the uterus, to be in good condition, and the urine was found to be normal.

The œdema of the skin and mucous membranes in these cases is evidently an angioneurosis, and is considered by the writer to be due to irritation of the vaso-dilator nerves rather than to paralysis of the vaso-constrictors. That acute œdema of the tissues may be caused by irritation of the former set of nerves is shown by electrical irritation in animals of the distal end of the bisected lingual nerve, when there ensues first hyperemia and subsequently a well-marked œdema of the tongue, which becomes manifest about ten minutes after the beginning of the irritation and keeps on increasing for ten minutes. The second group of symptoms which was prominent in connection with the above cases, namely, the periodic attacks of vomiting, are regarded by the writer as analogous to what has been described by Charcot as "crises gastriques" in connection with tabes, and by Leyden as "Periodisches Erbrechen," rather than as due to a sudden

œdema of the mucous membrane of the stomach, similar to that which took place in the skin and mucous membranes of the throat and larynx, as was suggested by Quinke. The results of treatment in these cases were unsatisfactory. Not one of the very many drugs which were tried, among which were atropine, hyoscyamus, and arsenic, had any appreciable power to check the number or severity of the attacks. The only method of treatment which was of benefit was general hygiene and regulation of the diet and method of living. When the œdematous condition of the skin was once developed, the application of ice to the parts seemed to act better than anything else, and œdema of the nucha repeatedly called for scarification of the same. Morphia, when given at the beginning of an attack of vomiting, seemed to shorten the duration and diminish the severity of the same, and ice internally gave the most relief to the burning thirst which accompanied the gastric disturbances.

## Reports of Societies.

### MASSACHUSETTS MEDICAL SOCIETY. SUFFOLK DISTRICT. SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE.

ALBERT I. N. BLODGETT, M.D., SECRETARY.

OCTOBER 14, 1885.

The section was called to order at 8.00 o'clock by Dr. R. P. ENES, the chairman. The records of the last meeting were read in summary, and after correction were approved.

Dr. MORTON PRINCE stated that the title of his paper at the last meeting of the section should be amended so as to read "Friedreich's Disease."

#### ELECTION OF CHAIRMAN.

The chairman announced that the first business to come before the section was the election of chairman for the ensuing year. A ballot was accordingly taken which resulted in the election of Dr. F. I. Knight as chairman of the section.

Dr. P. C. KNAPP exhibited a patient with

#### PSEUDO-HYPERTROPHIC MUSCULAR PARALYSIS,

and gave a brief *résumé* of the principal points of interest in the case. (See p. 435.)

Dr. J. J. PUTNAM remarked that often in the earlier stages of this disease the muscles of the upper extremity appear to be enlarged, and firmer than usual, sometimes seeming to be actually hypertrophied. The deltoid frequently presents the appearance of hypertrophy at this stage, and the muscles of facial expression are much more prominent than usual. The facial expression sometimes undergoes a marked change from the change in volume of the affected muscles. The gastrocnemii are often not weakened at first, but are actually stronger than normal. The disease seems to consist at first in a variation of the developmental force and direction, rather than in an actual degenerative process located in the spinal cord.

Dr. GOWLER has made many examinations of the nervous centres in this disease, but has not always succeeded in detecting pathological changes in these structures. In one case he discovered a portion of muscular tissue within the spinal canal.

Dr. C. F. Folsom read an elaborate and very interesting paper upon

"GENERAL PARALYSIS IN THE PRODROMAL PERIOD."

The patient was a clergyman who had always been well until recently, when he is said to have been affected with intermittent fever for which he is still taking quinine. It has been noticed that within the past year his disposition and character have undergone an unexplainable change, and that his sermons are quite rapidly deteriorating in excellence of thought, as well as in elegance of diction and purity of composition. The patient is himself aware of a change in this direction, but considers it due to a lack of energy upon his part, claiming that he might now produce equally good discourses if he would but make the necessary effort. He is, however, very well satisfied with his present sermons, but often preaches his old ones, as he considers them "too good to be lost." He is desirous of extending his usefulness, and has at times "exchanged" with other clergymen. On a recent occasion he preached in a strange church and made a very favorable impression. The congregation was accustomed to but one service on Sunday, but this clergyman thought that his sermons were so good, that he announced a second service, which, he laughingly states was attended by *one* person. He is not at all disturbed by any embarrassment of circumstances, but seems quite satisfied with whatever occurs. He wrote to Dr. Folsom making an appointment, which he found he could not keep, and sent a timely note asking for a change of appointment to some more convenient time. Upon being asked to write a page of ordinary paper he was quite at a loss, what to say; when he was asked to write the text of his sermon of the day before, he was utterly unable to recall it. He was equally unable to remember a clause or idea from the sermon, or anything connected with the services of that day. Upon removing his garments for the purpose of a physical examination it was observed that he wore two starched shirts, one outside the other. When asked why he dressed thus, he said that the outer one was the clean one of the day before, and he put it on in order to prevent it from becoming crushed by being placed in his valise. When asked why he did not lay the soiled shirt into the valise when he took the clean one out of it, he seemed to think that this would be a good idea, but he himself had not been able to think of any way, except to wear the one shirt outside the other. He several times made the remark that his urine was scanty owing to some disease of the liver. When it was suggested that the kidneys were the organs by which the urine was secreted, he seemed to be aware of his mistake and was amused that he should have made such an error. He complains of ringing in the ears, and some degree of pain in the head, which he attributes to the quinine prescribed for his "malaria."

His handwriting has changed to a marked degree within two or three years, and now presents the tabetic character quite distinctly. His present photograph by itself is not remarkable in any way, but compared with those of three and five years ago shows extensive changes in the expression, the facial outlines having become much less striking, owing to atrophy of the muscular structures of the face, by which the countenance is changing in the direction of imbecility. Speech is still fairly good, though when fatigued or confused, the utterance becomes very slow, and the patient

is often unable to pronounce words of several syllables without repeated efforts. Although a clock was within plain view, the patient would have missed his railway train had he not been reminded that it was time to go; upon which he made his arrangements in the most exemplary manner and left for his home. After a period of complete rest, he was again seen, when the symptoms of nervous derangement had so far disappeared that the most searching examination was necessary to detect the signs of any degeneration of the nervous structures. Only when the patient became somewhat fatigued did the signs of paralysis become evident.

These early and faintly marked symptoms are more carefully recorded in this case, and special attention is directed to them from the fact that they represent to some degree the "prodromal stage" of general paralysis, a period in the history of the disease, which the physician is seldom able to observe, as the symptoms at this time do not usually attract the attention of the patient or his friends; and medical aid is first summoned at a much more advanced stage of the malady, when cerebral changes have already occurred, and the case is hopelessly incurable. If anything in the way of treatment can be of any avail it must be employed in the earliest stages of the disease. The diagnosis of general paralysis once established, our prognosis in all such cases is at present invariably and unalterably hopeless. If any benefit is ever to be gained in this disease from therapeutic measures, it must come from treatment of its earliest stages before cerebral degeneration has occurred.

Dr. JELLY stated that he could add very little to the complete description of this forlorn disease which had been given by Dr. Folsom. The early recognition of the disease, and the study of the family history and individual traits are of the utmost importance. This was forcibly illustrated in a case coming under the speaker's personal observation, in which a wealthy and influential merchant had for two years been noticed to become gradually more and more erratic in business, and to make foolish and extravagant errors, and unaccountable mistakes. He was adjudged to be in the commencing stage of general paralysis, the stage of insane grandeur, and the friends were advised to remove him from business and to secure for him repose and perfect relaxation.

Before the nature and extent of the disease was appreciated by the patient's relatives, however, his entire fortune had been wasted, and when he was finally placed under medical care, his family were already in the depths of poverty. The patient was not benefited by treatment, but the disease rapidly advanced from the exaltation of the first stage to a condition of permanent and hopeless dementia.

Dr. J. J. PUTNAM said that while his own experience brings him in contact with comparatively few patients with general paralysis, yet he has been struck by the surprisingly large number of cases of this disease which have become known to him. There is no doubt that many cases exist which are entirely unsuspected until some painful or unsuspected event directs special attention to the individual, when the disease is at once distinctly recognizable. The statement of Dr. Folsom, that in many true cases of the disease there is astonishingly little which can be discovered in the way of positive symptoms, is unfortunately true. In many cases absolutely nothing can be detected, upon which

to base a sound diagnosis; and doubtless, oftentimes normal traits of individual character are ranked as features of the disease.

Dr. PUTNAM asked with how great a degree of certainty in many cases be diagnosed?

Dr. FOLSOM replied that in many patients the symptoms of this grave disease are very obscure. They may consist of three elements: diminution of muscular power; diminution of mental vigor, and derangement of the vaso-motor functions in the slightest degree. When notable changes in character or disposition occur, between the ages of forty and fifty, after the adult character of the individual may be supposed to have been firmly established, the indications are strongly in favor of general paralysis. Symptoms often entirely disappear from observation for a period of many months, but again recur after some trivial cause like loss of sleep or overwork. A sudden change in character and disposition in a vigorous man, without other explanation is almost invariably indicative of general paralysis.

Dr. JELLY asked if the prognosis is always necessarily so bad as has been supposed?

Dr. FOLSOM replied that he had never seen a cure in any case. There is no known record of cure in this disease. The prognosis is entirely hopeless. The therapeutics of this disease offers no encouragement at the present time. The whole question of treatment is in a most unsettled and unsatisfactory condition. The subject is in about the same condition as was that of pulmonary tuberculosis some fifty years ago. Cases generally come under the observation of the physician at too late a period, when organic changes have already occurred in the brain, and degeneration of the nervous and muscular structures have already taken place. At this stage no known method of treatment has ever been of the slightest avail.

Dr. F. I. KNIGHT spoke upon

#### RECENT METHODS OF TREATING HAY FEVER.

We all know how frequently the sanguine hopes aroused by some new form of treatment of disease prove delusive. We read of various suggestions and experiments, but there is a feeling against trying severe and protracted methods of treatment unless there is a reasonable prospect of benefit from such a course.

The history of "hay fever" is generally well known, up to the time when it was first associated with the pollen period of certain plants. There is no longer any question with the majority of observers that the pollen of ragweed and various other pollen-producing plants acts in a large proportion of cases as the exciting cause.

Dr. Beard was the first to make an advance in our knowledge of hay fever, which he did by collecting the history of many cases and examining all the circumstances attending the disease in many subjects and various localities. His researches led him to the conclusion that hay fever is to be ranked among the neuroses, and is the effect of a general or central disturbance rather than of a localized irritation.

Dr. Daly, of Pittsburg, in 1881 proposed a local irritation as the cause of all the symptoms, and advised the removal of the local condition of hypertrophy of the mucous membrane or other tissue by which the nasal passages are obstructed. This he tried in a series of cases and observed that the disease did not recur in the succeeding seasons.

Dr. Roe, of Rochester, uses the galvano-cautery extensively and with great success.

Dr. Sajous, of Philadelphia, considers that any mode of treatment by which an organic change is produced in the substance of the membrane may be followed by more or less complete relief from the disease, due to a modified condition of the anatomical structures at the seat of the local affection. He also recognizes the neurotic element of the disease and unites both theories in his conception of the disease. The local character of hay fever was strongly maintained by Hack, of Freiburg.

Harrison Allen, of Philadelphia, advocated the removal of obstructions, and thought that obstruction would be found in all cases.

Mackenzie, of Baltimore, thinks the name "Hay fever" objectionable for many reasons, and proposes the new appellation "coryza vasomotoria periodica" for the whole class of cases heretofore known as hay fever, rose cold, June cold, etc.

Mackenzie also mentions a case in which reflected irritation from ovarian disease seemed to be a factor in the production of this affection.

These observations are the testimony of reliable observers. There is no mistake as to their accuracy; and they go to show the variety of circumstances and diversity of conditions under which this curious disease is met.

The more recent ideas in relation to hay fever find expression in the systematic and persistent treatment of the local manifestations or complications of the disease, which has for its object the removal of the obstruction to the patency of the nares, whatever may be the seat, or nature of the obstruction, and the cauterization of the sensory areas by means of the galvano-cautery, carefully avoiding the olfactory region. The cautery, especially if preceded by the application of cocaine, is productive of but moderate local pain and its use has, in many cases, been followed by most gratifying results.

An example is the following case: A patient presented himself to Dr. Knight last spring, in whom the disease had recurred each year for seven or eight years in very severe form, obliging him either to remain in bed, or go to Bethlehem. Treatment was commenced by the removal of obstruction on one side, and the free use of the galvano-cautery in the anterior part of both nasal fossae, while the very posterior parts were cauterized by chromic acid. This was deemed advisable on account of the possible danger of exciting inflammation in the middle ear by the use of the galvano-cautery. The result was a most notable relief, though not complete exemption from the symptoms. Instead of going to bed, or even staying in the house, or going to Bethlehem, the patient was enabled to go about his usual business. He says in a letter, "the nasal symptoms were so much lighter that instead of constant flow of secretions and much sneezing, as in former years, this year I have only been troubled by working in the sun, or by very warm, dry days, when the discharge would be copious for perhaps half the day, with no filling up of the nasal passages to prevent me from breathing through nasal passages at any time. Asthma has troubled me hardly any, a very marked improvement, as it has formerly compelled me to sit up many nights. . . . On the whole I have been able to attend to my business every day; with comparative comfort most days, instead of the complete prostration by S. p.

tember 1st, of former years, and catarrhal cough lasting till winter. This year no cough to speak of, and no asthma to care for." He also speaks of the complete relief from nasal catarrh during the early summer, which had been previously quite troublesome. Another thorough cauterization, especially in the posterior region, will doubtless be even more successful.

Correspondence with gentlemen who have heretofore spoken most enthusiastically in regard to the use of the cautery in these cases, shows that the past season's work confirms them in their belief that at least a large proportion of cases can be cured, or radically relieved in this way. Dr. Mackenzie still insists on the importance of specific treatment of the neurosis as well as local treatment of the nose; and Dr. Roe still maintains the essentially local nature of the disease and its required treatment. Dr. Sajous thinks that superficial cautery, as formerly supposed by him, may not be sufficient in all cases, but that some, especially those with markedly nervous character, may require deep destruction of tissue.

We undoubtedly owe our patients who suffer severely from this disease, a trial of galvano-cautery, all serious obstruction having been previously removed.

DR. LANGMAID stated that his experience had coincided almost completely with that so clearly described by Dr. Knight, and he felt quite in the same way in regard to the disease. It is always important to discover the cause before instituting any form of treatment. It is a source of surprise that some practitioners discover such a large number of cases of hay fever. In a large hospital practice in diseases of the throat, there occurred last year but one (probable) case of hay fever. This year thus far, not a single case has appeared in the hospital clinic. In private practice the number of cases is quite considerable, and does not materially differ from the reports of other specialists. The disease is evidently to be regarded as a neurosis, and corresponds in all essential particulars to the observations of Mackenzie and Beard. A simple coryza may reappear periodically, and be produced by some cause which we cannot discover, but this is not necessarily hay fever. In hay fever there is always, either at the time of the attack or previously, obstruction of one or both nostrils; and no method of treatment can result in a permanent cure until this obstruction is removed. This must be done completely and thoroughly in order to be of more than transitory benefit. We are not prepared to say that a person with no obstruction in either nostril cannot have hay fever, but such cases must be extremely rare. The favorite theory of some specialists is that hay fever is due to some irritation of the "sensitive areas" within the nostril. These "areas" may be demonstrated by reducing the vascularity of the mucous membrane by means of cocaine, when many vascular points will still be visible. These are the "sensitive areas." They are very numerous and cannot be treated except by very extensive methods.

If the obstructive nostril is to be made patent, the first thing to decide, is the means to be employed for this object. Of all agents at our command, the galvano-cautery is undoubtedly the best. The crescent, or cold loop, is unquestionably the safer. The chemical caustics, chromic or acetic acids, are not satisfactory. We are not yet prepared to apply so severe an agent as the galvano-cautery to the surface of the entire nasal cavity. The present methods of treatment doubtless are better

calculated to relieve this distressing malady than those of former years, and will probably be of great service in very many cases, while some will still prove refractory to any known mode of procedure. The galvano-cautery is a means too severe to be employed in light or temporary cases. We are not at present inclined to sear the entire nasal mucous membrane in the free interval of a case of slight, or even moderate severity. The whole question of the applicability of galvano-caustic treatment to the majority of cases of hay fever is still *sub judice*. In the meantime, we must not lose sight of the neurotic element in the disease; we must look at the general condition of the patient, his constitutional tendencies, etc. Our information will be more advanced by observation of large numbers of cases than by any prescribed plan of treatment. One of the most remarkable of the phenomena attending the disease is the development of the neurosis at the seashore, and its lack of development in Bethlehem.

DR. DE BLOIS said that he had seen few cases, but those were very interesting. Last summer, he treated one patient by cauterizing the "sensitive areas" by means of chemical caustics, and the more the cautery was applied the greater number of "sensitive areas" were found, until both the operator and the patient were well nigh discouraged. A solution of cocaine was then applied, with the happiest result, the relief being absolute. In this case, there was no obstruction previous to the paroxysm, and nothing to remove. After the attack had subsided, the nostril was entirely free from any obstruction or malformation. It is possible that the formation of cicatricial tissue throughout the nasal cavity might prevent hay fever by destroying the normal textures of the nostril.

DR. F. C. SHATTUCK remarked that Dr. Langmaid had observed that obstruction of the nostril is almost always present. Is not ordinary coryza usually accompanied by obstruction of the nasal passages, and how does hay fever differ from a similar attack of ordinary nasal catarrh?

DR. LANGMAID responded that sensitiveness of the conjunctiva is a recognized feature of hay fever. There is a notable relief when the obstruction is relieved. Given a case of acute catarrh, it is impossible to say whether the case is one of simple coryza or the specific autumnal catarrh.

DR. KNIGHT remarked that for this reason some writers have suggested another name for cases of undoubted hay fever, that is, for that form of catarrh which depends on the specific irritation produced by a particular cause.

Especially irritant in so-called hay fever is the pollen of the rag weed. Bethlehem affords immunity to many because this plant does not grow there.

There appears to be an unusual number of cases at present, owing to the fact that certain practitioners have relieved some forms of the disease by the more recent procedures, and as a consequence, many old and incurable cases present themselves and swell the number of actual cases to surprising figures. Cases of spasmodic catarrh are sometimes observed which are excited by unusual causes. A young gentleman who was married last January has had five severe attacks of bronchial asthma which invariably came on suddenly during sexual intercourse, and have been the cause of much suffering. The patient never had asthma before marriage, and never at all excepting that excited when cohabiting with his wife.

DR. LANGMAID stated that he had known patients in the Rangeley region and in Bethlehem to have a paroxysm during, or after a south wind.

DR. PRINCE stated that one practitioner has reported several cases of inflammation of the middle ear from the extension of the irritation caused by the actual cautery, along the canal of the Eustachian tube.

DR. J. W. FARLOW said that a certain firm of manufacturing druggists had advertised tablets of cocaine for the relief of hay fever, and he had tried the remedy, with the result of a greater degree of irritation than was caused by the hay fever. Cocaine and bismuth diminish the sensitiveness of the membrane to a moderate extent, but they do not alleviate the tendency to sneezing. Cocaine and fuller's earth relieve the distress caused by the exquisite sensitiveness of the mucous membrane, but do not in the least restrain the flow of secretion. Cocaine in solution is quite useless. For the asthmatic distress as well as for reducing the flow of secretion, belladonna is of great service. Acetic acid has been of no service in two cases in which it was carefully applied to the mucous membrane. The actual cautery seems the best agent for most cases. One fact in regard to hay fever seems to be overlooked by the most of those who treat these cases. The susceptibility of the patient varies from year to year. Dr. Farlow employed the remedy so strongly recommended by the Rev. H. W. Beecher, and the patient escaped hay fever.

At a later period the same treatment was absolutely without avail in the case of same patient. The susceptibility varies according to the general health of the patient. When the general health is bad, the attacks of hay fever are usually severe.

DR. KNIGHT'S experience confirms that of Dr. Farlow in respect to the curative power of cocaine tablets. In one case the introduction of a single tablet was followed by the most distressing paroxysm of the entire season.

DR. FARLOW added that the cocaine tablets in the mouth afforded great relief to intolerable itching of the roof of the mouth and the palate, and this may contribute to the comfort of the patient.

DR. KNIGHT remarked that most gratifying results had been observed after the introduction of cocaine into the eye. The pain and lachrymation were quickly and completely relieved.

DR. BLODGETT spoke of a peculiar case which came under his observation, in which very severe attacks of asthma with complete obstruction of the mucus, lachrymation, itching of the mucous membrane, sneezing, and all the other discomforts of typical and severe paroxysmal catarrh were induced in a young gentleman by drinking champagne. No other cause had ever produced the paroxysms in this patient; and recently the susceptibility to catarrh has become so modified that a moderate quantity of champagne can be drunk without the occurrence of a paroxysm.

DR. KNIGHT said that he had known of one similar case.

DR. EDGES stated that ipecacuanha is a substance which causes paroxysmal catarrh in some sensitive persons. Dr. Edges himself is made very uncomfortable by inhaling the smallest amount of this drug.

DR. LANGMAID added that green coffee has a similar effect upon many people, and that some grocers are well aware of this peculiar property of coffee, and usually seek to keep out of its danger. Certain other sub-

stances also possess the power of exciting paroxysmal catarrh in those persons who are peculiarly sensitive, or who suffer from a personal idiosyncrasy in respect to these special irritants.

Adjourned at 10:05 o'clock.

## PHILADELPHIA ACADEMY OF SURGERY.

A MEETING of the Philadelphia Academy of Surgery was held October 5, 1885. Vice-President DR. R. J. LEVY in the chair.

### FOREIGN BODY CAUSING VESICAL CALCULUS.

DR. J. EWING MEARS: I desire to present to the Academy a urinary calculus removed from a patient in St. Mary's Hospital three weeks ago. The patient was a man from the interior of the State, fifty-six years of age, who had been suffering with bladder-troubles for nine months. There had been difficult micturition with pain, and the diagnosis of inflammation of the bladder had been made. Six months ago, in order to relieve the difficulty in passing water, he said that he had introduced a straw some two or three inches long. He was under the influence of liquor at the time, and the straw slipped from his grasp and entered the urethra. His symptoms then became more marked, and he came to this city. I introduced a sound, and discovered in the bladder the stone or mass which you see. The urine was carefully examined, and it was found to contain a large quantity of albumen and also phosphatic deposits. The question arose, in view of the man's habits, his age, and the condition of the urine, whether it would be better to perform lithotomy, or lithotripsy, or litholapaxy. Under the circumstances, I considered lithotomy the preferable operation.

I cut the man, and in so doing opened an abscess in the prostate, evacuating about an ounce of pus. I then entered the bladder and removed this cluster of calculi with a scoop. The bladder was then washed out, and in two weeks the man returned to his home with the wound entirely closed. At the end of this time, examination of the urine showed that its character was greatly improved.

It was certainly fortunate that section of the perineum was decided upon. The abscess was not recognized before operating, although exploration of the perineum was made. There was no pain, no swelling, and no tenderness.

The question arises in such cases as this, where the age of the man, his habits, and the composition of the urine indicate serious vesical and possibly renal disease, whether it is better to perform lithotomy or the crushing operation.

DR. LEVY:—How would the introduction of a straw account for this finfriated character of the mass? If a head of wheat or barley had been passed, it might explain it.

DR. S. W. GROSS:—Close examination will show that this is a spear of some grain, and that these little calculi are formed around the hairs of the grain.

DR. NAYLOR:—Could not the albumen in the urine come from the abscess in the prostate?

DR. MEARS:—It did not seem possible that the abscess communicated with the bladder. When I opened the abscess, I at first thought that it was connected with the bladder; but further examination showed

that such was not the case. The abscess might have been due to the impaction of one of these little masses in the duct of the gland, for I neglected to say that he had passed a number of these masses through the urethra.

#### EXCISION OF THE SCAPULA.

DR. JOHN BRINTON.—I have a specimen which I removed on Saturday last. It is of a good deal of interest: first, from the character of the tumor, and, secondly, for the magnitude of the operation required for its removal. The operation consisted in the removal of the entire scapula, performed on a girl of eleven years of age, for a formidable tumor. I may say here that the operation was unsuccessful as far as the life of the child was concerned, as the patient sank rapidly from shock, and died an hour after the termination of the operation.

The history of the case is simply this: A little girl, eleven years of age, living in the interior of the State, while playing under an apple-tree growing on a declivity, caught hold of one of the branches and swung herself. The branch gave way and she fell backward, rolling some six or seven feet, and striking the scapula upon a little projecting edge of stone. The pain from this continued for about an hour and then passed away, and there was no more trouble until last April, when she began to complain of pain over the right infra-spinatus fossa of the scapula. About the latter part of May or the early part of June, swelling made its appearance, and gradually increased until the tumor assumed formidable dimensions. At the time I examined it, the base of the tumor measured fifteen inches in circumference, and the general thickness of the shoulder was four or five inches greater than on the opposite side. The child was suffering greatly. The pain during the daytime was somewhat paroxysmal, but during the night it was almost continuous. For a number of nights she received from ten to fourteen drops of laudanum to give relief. During the night preceding the operation she was carried in a chair to give her as much rest as possible.

The case was seen in consultation, and the diagnosis of rapidly-growing sarcoma was made. It evidently involved the whole dorsum scapulae. After looking up the statistics of the operation, I decided to attempt the excision of the whole scapula. I ought to state that the parents were fully apprised of the nature of the operation, and all the parties concerned accepted the risks, owing to the urgency of the case.

On Saturday last the child was etherized, and, beginning at the point of the acromion process, I made an incision, carrying it to the posterior edge of the scapula. The incision was not at first carried the entire length, because I wished to divide the acromio-clavicular articulation as soon as possible. The idea was to save every drop of blood that could possibly be saved. I had gathered from the reports of cases that the great peril was from hemorrhage. I therefore commenced with a moderate incision, so as to divide the acromio-clavicular articulation. The incision was then swept across to the posterior portion of the bone. An incision was next made at right angles, and the incision (somewhat curved) was carried below the angle of the scapula and the four flaps dissected up. Then I commenced at the upper part of the bone, dividing the muscles; and then passed slowly down, dividing the muscles, taking the precaution, where there was any

chance of considerable hemorrhage, to include the mass of muscle within a ligature before dividing it. Where there was no danger, a mass of tissue was grasped between two large forceps, such as I formerly used for the extraction of bullets. The incision was then carried along the posterior border and the muscles divided; it was next carried under the inferior angle of the bone and the parts raised. The incision upon the anterior costa of the scapula was carried up, the vessels being compressed; and thus the parts being lifted. I opened the capsular ligament and turned out the head of the humerus. I next divided the heads of the muscle attached to the coracoid process. I had already divided the muscles along the spine. The bone was then readily lifted up and the hemorrhage was comparatively small. Performing the operation in this way, only one or two vessels required ligature after removal of the bone.

Examination of the tumor shows that it consists of two portions: that upon the dorsum, which is incised, and my finger goes directly to the bone, which is entirely destroyed, showing that the growth sprang from the periosteum. In examining the case before the operation, Dr. Gross and myself noticed a mass inside of the axilla. I myself thought that the mass must depend upon a prolongation of this mass of morbid structure. It, however, depended upon a mass of tissue developed from the venter of the bone. These masses are continuous at the junction of the upper and middle third of the inferior costa. It was the posterior mass which projected into the axilla. This lifted the scapula from the chest and increased the apparent size of the tumor on the dorsal surface.

Statistics show that the mortality following the operation is greater where a portion of the bone is left than where the entire bone is removed. In forty cases of entire removal, the mortality was twenty per cent.; after partial removal, twenty-one or twenty-two per cent. Where the scapula was removed after amputation of the arm, the mortality was twenty-four per cent.

The microscopic examination of this growth by Dr. Longstreth shows that it is a well-marked example of round-celled sarcoma.

One other case of complete excision of the scapula was performed by Professor Agnew some years ago. The patient died in a short time from shock. Two partial operations were performed by the late Professor Gross.

DR. R. T. LEVIs.—Once when contemplating an operation of the same kind on an adult with a large tumor, — an operation which I did not perform, — I determined upon an expedient to prevent severe hemorrhage. That was to tilt out the scapula and apply Esmarch's bandage around it, enclosing the axillary artery high up. To prevent slipping a bandage was to be placed in front, under the rubber tube, drawing it to the opposite side.

DR. J. EWING MEARS.—We should not expect much hemorrhage from a tumor which seems, as this does, to be, as it were, encapsulated. In this case the muscles are not attached to the growth. Where, however, there is a malignant growth which infiltrates the tissues and envelops the ramifications of the blood-vessels, the bleeding may be severe and prove fatal.

I would ask Dr. Brinton if, when he turned up the mass towards the axilla, he brought into view the axillary vessels?

DR. BRINTON.—I did not. I saw the subscapular artery and nothing else.

DR. MEARS.—I refer to that point for this reason: that in some cases, where the growth involves the entire arm, it is necessary to extirpate the scapula with a portion of the clavicle, and also the entire arm, and it has seemed to me that in such cases it might be possible, by tilting up the scapula, to reach the axillary artery and surround it with a ligature before amputating the arm. I have not found this method of controlling hemorrhage prior to disarticulation referred to.

In considering the mortality-rate after excision of the scapula, it is desirable to consider the causes for which the operation is performed. It has been performed for necrosis, for gunshot injuries, and for tumors such as enchondromata, sarcoma, and malignant growths. In necrosis of the entire scapula, where the disease is of some duration and where there is great inflammatory thickening of the periosteum, removal of the scapula is comparatively easy. An incision made along the spine to the posterior border and then continued along the posterior border will enable the operator to lift the periosteum with an elevator, periosteome or the handle of a knife. In that way the muscular attachments may be severed. Such an operation gives a better mortality-rate than do operations for malignant growths, and, if I remember, better than for operations for the removal of portions of the bone in compound comminuted fractures, the result of gunshot injuries.

DR. BRINTON.—In this case there was no difficulty in compressing the subclavian artery with the finger. This was done by Dr. Uearn. In some of the reported cases the pressure has been made directly. In some of these cases, as soon as the acromion-clavicular articulation has been severed, the coracoid process has been broken and pressure made directly upon the artery.

DR. LEVIs.—Did the patient seem much depressed by the anæsthetic?

DR. BRINTON.—She came from under the ether very well.

DR. HEARN.—The child was never thoroughly anesthetized at any time. I do not think that the anæsthetic had anything to do with the fatal result.

#### CONGENITAL MALFORMATION OF COLON.

DR. CHARLES B. NANCREDÉ.—I have here specimens of some little interest. They are the terminal part of the rectum and the caput coli, which were removed from an infant, fifty hours old. The child had been delivered with instruments, and seemed to be in perfect health until the second night, when the nurse sent for me and said that there was something wrong; that the child was crying and straining, but had not soiled any napkins.

On examination, I found a well-formed anus, into which I could introduce my finger one-third of an inch. It was a female child, and I could therefore make a thorough examination; but I could detect no bulging at any point. As it was twelve o'clock at night and the distention was not great, I gave an opiate, and the next morning at eleven o'clock, Dr. Ashurst met me in consultation. Neither of us could feel any bowel, but we thought it right to make an effort to reach the bowel. I dissected along the hollow of the sacrum up to the promontory, but could not feel the gut. We then decided to perform the operation in the right

inguinal region, and I opened what I supposed to be the sigmoid flexure; but it proved at the post-mortem to be the caput coli. As soon as the peritoneal cavity was opened, about an ounce of serum escaped, and with it the right Fallopian tube, which was intensely congested. There was marked peritonitis. The child lived four and a half days after the operation. The mæconium passed freely, and afterwards the discharges were natural. The child died from exhaustion, evidently due to the peritonitis.

The post-mortem showed that if I had detected the bulging bowel, which I must have felt, as it was near the end of my incision, I should almost inevitably cut through two layers of peritoneum. There was a space about as wide as a director where the bowel was not covered by peritoneum, and I should have left behind the peritonitis. The question arises in these cases, if peritonitis does set in so early, and if death results, as it usually does, from peritonitis, whether it is worth while to add the double danger of two operations, especially in female children where it is impossible to detect any sign of the bowel.

DR. LEVIs.—Does Dr. Nancréde think well of operating before the sac becomes distended?

DR. NANCREDÉ.—Unless something is done, the patient dies early. I notice that Bryant has called attention to the fact that peritonitis sets in very rapidly, and that in true obstruction, death is frequently due to peritonitis. In this case, the peritonitis was very marked at the end of fifty hours.

DR. LEVIs.—I have never done any operation except in the fundament. I would not like to save a child's life with an anus anywhere but in the fundament. I have always been able to find the sac and to bring it down and stitch it to the skin.

DR. O. H. ALLIS.—At the post-mortem, how far were the two blind sacs from each other?

DR. NANCREDÉ.—I should say about an inch. I must have touched the bowel with my finger, but did not recognize it. Bryant strongly advocates the operation in case of deficient rectum, and the opinion of a man who has had such an exceptionally large experience in the surgery of the bowel in general, having reported eighty-two or eighty-three colotomies, ought to count for a good deal. There seemed to be no more difficulty in retaining the faces in this case than where the anus is in the normal position. Sometimes hours would pass without anything coming. In this case, I think it would have been impossible to bring the bowel down and stitch it.

#### TREATMENT OF CARBUNCLE.

DR. JAMES COLLINS.—I have lately treated two cases of carbuncle on the back of the neck by a method which seems to have some advantages. The patient is put under the influence of an anæsthetic and a linear incision made. I then take a scoop and remove all the necrosed tissue, and wash the parts thoroughly with an antiseptic solution of mercuric chloride. I then put in a drainage-tube, and insert two stitches to bring the central part together. Each day the cavity is thoroughly washed out with the antiseptic solution. The patients have done well, and the cicatrix have been less than after any other method I have tried. The success depends upon the removal of the necrosed tissue and the use of the antiseptic solution.

DR. S. W. GROSS.—The plan of Dr. Collins is, I think, based upon proper principles. I consider it far

the best operation yet suggested. By scraping away all the dead tissue, he gets rid of the micrococci which produce putrefaction, which give rise to the sloughs. The application of the corrosive sublimate destroys the micrococci which line the walls of the cavity, and in that way removes the cause of the disease.

DR. MEARS.—I would ask if Dr. Collins, in scooping out the dead tissue, found anything like a thickened wall limiting the mass to be removed, and if he was able to satisfy himself that he has removed all the dead tissue.

DR. COLLINS.—I keep on scooping out until I reach a denser structure. The difference seems to be in the denseness of the tissue. The healthy tissue seems to be firm.

DR. LEVIS.—The operation of excision of carbuncles in their incipency has been repeatedly advised and practised. In cases of constantly-recurring carbuncles, I think that excision would be of service.

DR. HUNT.—I have been trying to recall a case of carbuncle on the back of the neck of a woman. I cannot recall a case. I would ask if this is the experience of the other members, and, if so, what reason can be given for this peculiarity?

DR. COLLINS.—I remember one severe case.

DR. LEVIS.—I cannot recollect a case.

DR. NANCREDE.—I have seen a fatal case in which the carbuncle was on the side of the neck of a woman.

## THE AMERICAN ACADEMY OF MEDICINE.

The Ninth Annual Session of the Academy held October 28 and 29, 1885, in the city of New York.

The meeting was called to order by the President, ALBERT H. GHON, M.D., of Washington. Prayer was offered by REV. HENRY J. VANDYKE, JR., of New York.

The first paper was read by DR. ROBERT L. SIMBETT, of Carlisle, Pa., and was entitled:—

### THE STUDY OF MEDICINE AS A MEANS OF EDUCATION.

The reader first referred to the various elements in education, considering time the most important of these.

Taking up the subject of medical treatment, preliminary examination, with graded courses and frequent examinations were heartily recommended. A protracted course of academic training is necessary for a proper study of medicine.

The speaker concluded by saying that a State Medical Examining Board with full authority to examine all practitioners, irrespective of the degrees they may hold, would do more to elevate the profession, than all other means combined.

DR. CHARLES MCINTIRE, of Easton, Pa., then read a paper on

### MEDICAL SUPERVISION IN STUDENT LIFE.

This paper assumed that modern life made a greater demand upon the time and energies of the individual to the detriment of his health and development. It was considered impossible to diminish tasks and give more time to rest and recreation. There is no way known to shorten the period of rest, so something should be done for recreation. The plan suggested was the usual one given by students on these subjects.

A careful physical examination at the beginning of school life and a series of graded bodily exercise under medical supervision throughout school life was recommended. The end aimed at is to give such tasks as will tend to strengthen the weaker parts.

DR. HENRY O. MARCY, of Boston, read a paper on

### THE CLIMATIC TREATMENT OF DISEASE, WITH AN ILLUSTRATION OF WESTERN NORTH CAROLINA AS A HEALTH RESORT.

The fundamental factors of the zymotic diseases were first reviewed from our present knowledge of the rôle of the bacteria and the question of the wise adaptability of the individual to his surroundings was considered as the best definition of climate. A *résumé* of the latest investigations of climatologists was given with reference to, and the results obtained by the mountain health resorts of Europe and America. The deductions of the writer were that good must be looked for in the benefit to be obtained to the individual in the improvement of his resisting vital powers and invigoration of his cellular tissue regeneration, rather than in the escape from his bacterial enemies. The larger portion of the paper was devoted to the consideration of this new and important phase of the question of climate.

The higher Alleghanies in Western North Carolina were described at considerable length as offering mountain health resorts of a character well suited to a variety of diseases. The deductions were based on a long tour of personal investigation made during the last summer as a sanitary study.

The meeting then adjourned.

### EVENING SESSION.

The President, DR. ALBERT H. GHON, A.M., M.D., read his annual address, entitled:—

### WHAT IS MEDICINE?

He said that the place of the Academy was not to be sought among the pathological, clinical, sanitary and other national associations. It antagonizes none of these, but seeks to cement all into a compact unity.

Referring to the slow growth of the Academy, it was stated that one of the reasons was to be found in the fundamental condition of membership, restricting fellowships to graduates in medicine who have received degrees in letters. As the coöperation of every educated man interested in the objects of the Academy is desirable, he was of the opinion that the time had come when every limitation to fellowship should be removed, except the solitary requirement that the candidate shall be in fact, as in title, "learned in medicine," and in all else that this term implies, but he would make it impossible for any one unfit or unworthy to enter, though he come with an armful of diplomas, have subscribed to the most inflexible of codes, and no matter what faculty, society or institution he may be delegated to represent. The nomination should be accompanied with the fullest record evidence, and be made long enough in advance, from six to twelve months, to enable the council to determine each man's fitness.

A second reason why the Academy had not met with more pronounced sympathy and support was its necessarily hostile attitude to institutions and individuals who defy the principles of its constitution.

The Academy encounters a third obstacle in the lukewarmness of its quasi-friends; some damning it with faint praise, others exuberant in private but chary of public endorsement. Reference was made to the case of a medical editor, who could not follow his wish in this respect on account of policy. The editorial columns of the medical press were preëminently light-toned, but the publishers were inconsistent in permitting under the same cover, advertisements of medical concerns, drug factories, and proprietary clap-nets. Why should the business venture of men who get up sham colleges be advertised in reputable journals? The *New York Medical Record* commends the recent action of the Florida Medical Association in resolving against the advisability of establishing a medical college in that State. These are encouraging signs, offsetting the fact that thirty-nine of the eighty-seven regular schools in the United States are only fifteen years old, and twenty-one not over five years. Reference was made to the fact that trashy communications of illiterate M.D.'s, were published simply because they were subscribers. The journals only reflect sentiment. Let us ask ourselves the question "What is medicine?"

If we look to this Academy for the answer, we shall find that it is the most profound and ennobling study which can engage the intellect of man. This is not the popular idea, which is, that medicine is only something in a box or bottle that is prescribed by a man or woman who has acquired more or less skill in administering the particular remedy appropriate for each disease. Like other professions whose offices are called for by the disagreeable incidents of humanity, it is only tolerated as a necessity. Sham aristocrats look down upon it, others hire its members as they do their cook and cabman. In military and naval services it is sought to degrade them. The ministry of the suffering and afflicted is nowhere regarded as an outcome of the study of the stupendous and sublime mysteries of existence. In the national councils, in military and naval organizations, in civic administrations, who thinks of giving a first place to the physician, although his are the mental attainments which fit him best for counsel in all that concerns the welfare and progress of the human race?

The science of medicine involves the knowledge of everything that relates, however remotely, to the existence of man, his place in nature, his origin, growth and development, preservation and continuance. The prevention and cure of those abnormal conditions which tend to his destruction, are but one chapter in the volume, which coming near the end, cannot be read understandingly without the thorough comprehension and diligent study of all that precedes. Medicine is so far-reaching in its sources and so connected with every other branch of knowledge that he who would begin its study must first have drunk deep of the well-spring of human knowledge. Medicine is a science of such proportions that only a well-educated man can master it. Is this the view entertained by the profession at large? What are the facts?

Let us see how the profession is recruited. Ordinarily a youth becomes a doctor, as it were, from a whim, and there are others, no longer young, and having failed in other occupations, who hope to make money by this, knowing nothing of its responsibilities and requirements, without aptitude, ignorant, illiterate, etc. Such a one goes to a college and as a first-course student listens to lectures on anatomy, practice, chemistry,

surgery, etc., one after the other, without understanding a word of the technical language. Seventy-nine colleges require evidences of preliminary education. In most this is only nominal. Recent instances of illiteracy on the part of graduates before examining boards are the following, "volume of mureurey," "cours at Belevieu," "anylitic," "assend," "admission," "diamete of the earth ninty-two thousand miles," "the field of the cloth of gold, some kind of tapestry," "an alternative acts like food on building up system, and are favored in their action by stonachic, or anything which arouses the system to action." Could the man who after graduation says "was began," and spells "gravatation, feneral, superating, corpsels," etc., have ever comprehended the language used by the teachers?

Why should medicine be cheapened to every purchaser and the college debase its teachings to their limited understanding. A collection of these presented to American medical colleges during the last five years would be more entertaining than "English as She is Spoke." Only the utter ignorance of elementary chemical principles on the part of the men who study medicine, has made chemistry one of the seven chairs. It belongs to an academic course.

What then, can medicine be to the ignorant numbers who are annually mustered into the ranks of the profession? To these men, it can have no other aspect than that of a trade. Many enter upon it as a money-making vocation. It was taught them as a source of pecuniary profit, and they practise it for the fees they get. Manifestly, then, medicine is not the same to all men, even medical men. If improper men can be excluded from national services, why not from state, county, and city medical societies? This should be done for the protection of the community. Where a drug clerk kills one victim by his carelessness, he saves a hundred by recognizing errors in physician's prescriptions. (Examples from apothecaries' files were given.)

The debasement of medical education to the capacity of the ordinary purchaser of a diploma, will eventually cause the profession to deserve the reproaches of its friends. The public gauge the profession by the men with whom they most frequently come in contact. The wise physician does not hesitate to say, "I do not know." The typical doctor affects an omniscience in inverse ratio to his knowledge.

Until the mystery of the first departure from health is made clear, all our therapeutics must be empirical, and fundamental methods of cure be speculative. If we have not learned where disease begins, we have at least learned that the follies and weaknesses of man have in their wake a multitude of ills, and these we can prevent, and the wise physician, learned in all that pertains to the normal life of the body, aims to protect it from these evil influences, which his experience has taught him will do it harm.

Preventive medicine has at last attained recognition as the highest aim of the physician's art. It establishes new relations of the physician to the social system. It is not creditable to the intelligence of the age that in the department controlling material affairs, among bureaus of labor, statistics, agriculture, education, and so on, there is no bureau of public health. Preventive medicine has more to do than warding off epidemic visitations of great scourges. Its most important duty is to consider the impairment of health of growing children through the sanitary defects of our school system, the prevention of insanity, the repress-

sion of crime. It is too much to expect antidotes for every microscopic germ. The tiny swarms around us are at once our friends and foes. If we do not antagonize them, they purify the air we breathe, the water we drink, the dirt we tread, and prey upon our natural waste; it is only our own folly that causes them to turn and rend us. We are too prone to hasty generalizations. We inconsistently denounce the doctrinaires, who affect to believe in the paenagoric virtue of similars, and ourselves find cure-alls in quinia, cocaine, germicides, etc.

Hence the greater need of impressing upon the tyro in medicine the fact that there are underlying principles never to be lost sight of. The chair of Institutes of Medicine has gradually been supplanted by that of principles and practice. If he were to banish chemistry and physics from medical colleges, he would establish a chair of the philosophy of medicine, to include the history of medicine, medical literature, medical jurisprudence, and medical ethics.

Reform has been hampered by adherence to existing methods. It will not do merely to establish adjunct chairs. The starting point must be the requirements of a thorough preliminary education. Four annual terms are necessary. Descriptive anatomy and materia medica are enough for the first year. Histology and practical microscopy, physiology in all its relations, and the mechanical processes of pharmacy, should occupy the second year. Hygiene, general pathology, and general therapeutics for the third year. Special pathology, special therapeutics, the philosophy of medicine, medical history, jurisprudence and ethics, for the fourth year. A fifth year may with advantage be devoted to clinical experience under supervision.

Medicine has no need to rear its superstructure on any other foundation than the broad basis of fact. It has been dragged down to the level of commonplace occupations by the dissensions incited by the dogmas of theorists. When all physicians stand on the plane of higher medicine, there will be less tendency to diverge into extremist classes.

Is our estimate of medicine visionary, and have we sought the impracticable? Must we silence our voices because few care to hear, and cease our efforts because the task is difficult? Must we tread the beaten track, lest we offend prejudices, antagonize pecuniary interests, and upset established orders? Not on this account shall we hesitate, if the truth be with us. The ethics of medicine rightly denounces fraternity with charlatans and quacks. Is the dishonor less if we degrade a noble profession by admitting to its rights and honors those who are ignorant, illiterate and incompetent?

In notes on the aboriginal tribes of South Formosa, contributed to the Medical Reports of the Imperial Chinese Customs, it is stated that a tribe called the Amis believe that thunder and lightning are caused by two spirits, male and female, named Kakring and Kalapiet. A domestic row arises, the husband in his anger knocks about the household effects, thus causing thunder; and the wife, in the height of her effort at retaliation, moves herself, which gives origin to the lightning. Uncovering the person is a favorite way of showing anger, scorn, and contempt among the Amis-females. Earthquakes, they say, are caused by a pig scratching itself against an iron bar stuck in the earth.

## Medical and Surgical Journal.

THURSDAY, NOVEMBER 5, 1885.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly, by CUPPLES, UPHAM & CO., Boston. Price, 16 cents a number; \$5.00 a year, including postage, to subscribers in the United States and Canada. Foreign subscribers are charged the postage in addition.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.*

CUPPLES, UPHAM & COMPANY,

283 WASHINGTON STREET, BOSTON, MASS.

### ANTISEPTIC SURGERY IN AMERICA.

THE interest in antiseptic surgery in this country since the first introduction of the method has been very great. It has had many earnest advocates, but it has made its way into general use somewhat slowly. The effects of Listerism upon those who have failed to practice it, have been much the same here as in the older countries in enforcing a much greater dread of dirt and a much stricter meaning to the term cleanliness, and the benefit to surgical practice has been, in this way, very great indeed. Antiseptic surgery, strictly speaking, has been often attempted in certain severe operations by those who have failed to use it habitually, but not always with that faith necessary to the carrying out of all its details, and not always with the success that encouraged further efforts. Indeed, it is doubtful if it is possible to carry out the details properly unless it is practiced so habitually as to render the details a mere matter of routine.

The signs of the times, if we read them aright, show that the system is becoming a part of American surgery; we refer to certain papers which have recently been reported, and particularly to that of Dr. Stephen Smith, read before the New York Academy of Medicine; Dr. Bolles recently read before the Boston Society of Medical Improvement, and the Annual Address of Dr. Paddock before the Massachusetts Medical Society.

Dr. Smith shows the results of the change from the older methods at Bellevue Hospital, and claims results that are almost beyond belief. He appears to speak for his colleagues as well as himself, and to show that antiseptic surgery is the rule of the hospital, and not merely the whim of an individual surgeon.

The paper of Dr. Bolles, an abstract of which appeared in our last issue, with the discussion that followed, also shows that antiseptic surgery has obtained a strong hold in Boston, especially among the younger surgeons.

These two papers show that sustained and systematic efforts are made in two of the chief cities of the eastern portion of the country to carry into effect the

improved treatment of wounds, and that the results of such efforts are found in the practical banishment of septic diseases, high temperatures and excessive suppurations, while Dr. Paddock's address, which was published in this JOURNAL in July, was a plea for the use of antiseptics among practitioners who are only occasionally called upon to act as operative surgeons. One thing is especially noticeable—the increasing simplicity in the methods employed. Many who revolted from the use of the cumbersome spray, take kindly to the simpler methods. This comparative simplicity is well exemplified in the closing sentences of Dr. Smith's paper:—

"Cleanliness is the one great object sought to be attained in all operations. Whatever may be the final conclusion of scientific students as to the cause of putrefaction in wounds, practically it is determined that the surgeon may, with the most absolute certainty, protect an ordinary open wound from suppuration. To effect this object he finds that he has simply to resort to those measures which are known to secure perfect cleanliness of the wound. The agents now relied upon and found efficient are: 1. Soap and water to external parts. 2. Carbolic solutions for the instruments. 3. Bichloride solutions to all surfaces and tissues. 4. Iodoform for external dressings. We may summarize the conditions regarded as essential to success as follows, that is: *A clean operator; clean assistants; a clean patient; clean instruments; clean dressings.*"

It is interesting in this connection to quote from one who believes himself an opponent of antiseptics. In the last edition of his surgery, which has but recently issued from the press, Dr. Ashhurst remarks that "results quite as good as those of Professor Lister's followers are obtained by surgeons who rely simply upon enforcing cleanliness and attending to the constitutional and hygienic conditions of their patients without adopting any exclusive mode of dressing."

The most spirited opponents of a movement often contribute greatly to its progress by their criticism. They make plain the difficulties and dangers of the movement they criticize, and the absurdities into which its advocates may have fallen, and contribute in their turn, by their opposition, to the establishment of the truth. On the same page from which we have quoted, Dr. Ashhurst shows that the antiseptics have occasionally forgotten their patients in their attempts to destroy the disease germs.

The necessity for scrupulous cleanliness is the common ground on which antiseptists and their critics agree. The difference lies simply in the manner of securing it. How much of the present methods will survive even ten years is very uncertain. Probably new methods and new antiseptic substances will be introduced. The conscientious cleanliness will without doubt remain. It is gratifying to know that American surgeons are working at the question of the best method of treating accidental and operative wounds, and they give promise of valuable aid in its solution.

## PERINEAL LACERATIONS.

THERE is no accident connected with the accoucheur's art more dreaded than rupture of the perineum: there is no subject more fruitful in discussion at medical meetings than the means of prevention and treatment of the accident.

As for the frequency of this lesion—excluding the slight tears which in primiparae are generally unavoidable, and the more serious rents, which still spare the posterior part of the perineal body occurring, according to Olshausen, in twenty-one per cent. of primiparae, and four per cent. of multiparae—lacerations extending quite through the perineum and including the sphincter are comparatively rare in the experience of most practitioners: many old accoucheurs have never had a bad case in their lifetime.

The causes of this accident are manifold. There are dyscrasic causes, producing a friable state of the tissues; anatomical, including strained pelvis, cicatricial contractions, and rigidity of the vulvar outlet; physiological, due to mal-presentations and to the mechanism of the labor, which may be so tedious as to destroy by pressure the elastic resistance of the perineum, or so rapid as to expel the head before dilatation has been effected.

As for prevention: it is noteworthy that the antiquated custom of "supporting the perineum" during the stage of expulsion has undergone modification in the direction of a more equable distribution of pressure upon the periphery of the vaginal orifice. The support is now applied, not so much to the perineum as to the presenting part, according to Hohl's method, as endorsed by Olshausen and Lusk. The patient is enjoined, as far as possible, to refrain from voluntary effort, and, ergot, if given before the birth of the child, is given with great circumspection. Goodell advises "in order to remove the strain from the thinned border of the vulva, and promote the elasticity of the tissues, to hook two fingers into the anus and draw the perineum forward during a pain." If laceration seems inevitable, it may sometimes be proper to avert this misfortune by slight lateral incisions<sup>1</sup> through the tense ring of the vulva.

If a laceration involving the entire perineum has taken place, there can be no doubt as to the propriety of immediately putting in a sufficient number of silver sutures to keep the torn parts well together till union shall have been effected. This is not always possible;

<sup>1</sup>This operation (episiotomy) is a favorite one at the Vienna Lying-in Hospitals. Michaelis was the first to perform it in 1799. The name episiotomy was suggested by Child, in his treatise on Midwifery, in 1812, though it had not then been attempted, where it is an elaborate article on the subject by Code and Code in the Arch. E. Chir. for 1854. "Cases of rupture, in spite of episiotomy, sometimes occur one and four tenths of Code's cases—a very rare percentage." Dr. Wilcox, of New York, in the New York Medical Journal, August 15, 1885, advises to choose the left lateral position. "The operator, controlling the advance of the child's head with his left hand, takes the blunt pointed straight bistoury in his right. He inserts it at the commencement of a labor pain between the presenting head and the thinned border of the vulva, and, as the pain subsides, he makes a deep incision. The bistoury is held in this position till the apex of the pain, immediately after the apex has been reached, the edged bistoury is turned at a right angle to the edge of the vulva, the head being prevented from being forced out by the pain, the incision is made outwards to one inch and some much through the resisting structures. The labor is now conducted as usual, the head, as a rule, passing out at the next pain."

in fact a great proportion of primary operations are unsuccessful, owing to the irritation of the lochial discharges, which cannot readily be kept from infiltrating the flaps of the wound. Numerous expedients, such as packing the vagina with absorbent cotton, have been proposed to remedy this evil, but none of them are very practicable.

With regard to the details of the operation, no great amount of skill is requisite. The sooner after the rupture ligatures are applied the better. Silver sutures are better than silk, being less irritating; they can also be kept in several days longer than silk, a real advantage in many cases. If, however, silver wire be not at hand, carbolized silk may be used, but the old-fashioned quilled suture is not to be insisted on. In fact many surgeons have abandoned the quilled suture in perineal operations, as the bits of bougie used for this purpose are apt to cause irritation and sloughing. A very good way is to pass in three deep sutures—the first directly in front of the anus,—and three superficial ones, the latter being necessitated by the gaping of the superficial portion of the flaps which results from the deep stitches.

With regard to the after-treatment, the utility of drawing the urine by catheter the first few days is apparent, but there is not entire agreement as to whether the bowels should be kept confined or soluble; though the weight of authority seems to be in favor of maintaining a constipated condition the first seven or eight days, by means of diet and opiates. There is no doubt that excellent results have been obtained by this practice, and at the same time failures have been attributed to it. Dr. Granville Bantock reports in the *London Lancet* (Part II, 1880) several cases of ruptured perineum in which the primary operation was unsuccessful owing to long confinement of the bowels; union seemed good and the perineum sound at the time of removal of the stitches, but the evacuation was so solid, and came with so much force, that the whole gave way. In subsequent operations (immediate or secondary) Dr. Bantock pursued a different course.

The quietude of the bowels for several days was ensured by their thorough evacuation prior to the operation, and by a light diet. On the fourth day he began to administer some mild aperient, and for this purpose a pill, consisting of one grain each of the compound extract of colocynth and hyoscyamus, was given every four hours till the bowels acted. He believes it of importance to get the bowels to act before the sutures are removed, as the sutures strengthen the perineum and anal opening.

The immediate operation may be unsuccessful as far as the restoration of the perineum is concerned, and yet the functions of the rectum may be restored, even in cases where the sphincter has been torn. Under the most unfavorable circumstances considerable repair is likely to take place; a torn sphincter may unite and a rectal fistula may heal. There has of late years been much difference of opinion as to the real function of the perineum; some, as Emmett,

holding that to support the uterus and keep it in place is not one of the offices of the perineum, that "a simple laceration of the perineum, even to the fibres of the sphincter and produces no inconvenience after the parts have healed, and only occasionally do we find disturbance of a reflex character due to the presence of cicatricial tissue." Others, on the contrary, and notably, Dr. T. Gaillard Thomas, teach that the perineum is the chief support of the pelvic viscera; "it sustains and prevents prolapse of the anterior wall of the rectum, and of the anterior wall of the vagina; . . . upon the posterior vaginal wall rests the anterior, upon this the bladder, and against the bladder the uterus, all of which depend in a great degree for support upon the perineal body."

There is much to say in favor of the view of Emmett, as every physician in large practice has in mind cases coming under his observation where complete loss of the perineum has never, through long years, entailed any grave discomfort or inconvenience. Nevertheless such experiences pertain rather to the earlier years of women when the health is vigorous, the tonicity of the tissues good, and the pelvis has its usual amount of adipose tissue. Later in life when there is a loss of this adipose, and a general relaxation of the tissues, with a spongy state of the connective tissue, prolapse of the vagina is exceedingly likely to take place, and with it, displacement of the bladder and uterus, perhaps also of the rectum; it is needless to say that no condition more powerfully predisposes and contributes to this train of calamities than loss of the perineal body.

Hence it is that there is everywhere a predominant interest in the prevention and cure of perineal lacerations. Hence the desirability, where a first attempt to repair the mischief has failed, of trying again at an early date.

#### MEDICAL NOTES.

— It is announced that the number of candidates for the vacancies in the medical school at Kieff, Russia, is so great that an order has been made, restricting the privilege of studentship to those who have received their previous education at a gymnasium. The Russian medical schools are becoming so crowded that some method must be resorted to for diminishing the number of applicants. It is impossible to give clinical instruction satisfactorily to such large numbers as there are at present. It is also stated by a Russian political journal that all students who are not Christians are to be deprived of their stipends. This is specially directed against Jews, who mostly belong to the medical faculties, and who, it is said, form a tenth part of the whole number of medical students.

#### NEW YORK.

— Two cases of small-pox have broken out among the patients in Charity Hospital, Blackwell's Island. Both the patients are male adults.

— Dr. Cyrus Edson, Chief of the Second Sanitary Division, recently seized at various meat markets in

the city the carcasses of 28 hogs which had been suffering from hog cholera when they were butchered.

—At the eightieth annual meeting of the Medical Society of the County of New York, held October 26, the following officers were elected for the current year: President, Dr. Daniel Lewis; vice-president, Dr. Lawrence Johnson; secretary, Dr. Wesley M. Carpenter; treasurer, Dr. Orlando B. Douglass.

—Three cases of yellow fever arrived at Quarantine on board the steamship Niagara, of Ward's Line, from Havana, on the 20th of October. The patients, who are all seamen, were removed to the hospital on Swinburne's Island, where one of them afterwards died.

—The Society of St. Luke's Hospital, held its annual meeting October 18. The annual report showed that 1,561 patients had been treated in the past year, at a daily cost per capita of \$1.14½. The largest number of patients in the hospital at any one time was 192, and the average daily number was 164. The number of days of hospital care was 59,782, and of this number 51,554 were gratuitous.

—The ninth annual commencement of the training school for nurses of the Charity and Maternity Hospitals on Blackwell's Island was held, under the auspices of the Commissioners of Charities and Correction, at the Carnegie Laboratory in East 26th Street, on the 29th of October; when there were eleven graduates. Addresses were made by the Rev. Dr. McGlynn, ex-Mayor Wickham, Dr. F. N. Otis, of the Board of Visiting Surgeons, and Dr. L. L. Seaman, Chief of Staff of Charity Hospital.

—Information has been received by the Board of Health that a number of milch cows on a dairy farm near William's Bridge, a short distance from the city, were suffering from pleuro-pneumonia. The farm being in Westchester County, beyond the jurisdiction of the board, notice was sent to the State Board of Health and the health authorities of Westchester County. Professor Liantard, veterinary surgeon of the State Board of Health, is now making an investigation of the outbreak.

—The first annual meeting of the Montefiore Home for Chronic Invalids, was held October 25. It was opened a year ago with 7 patients, but the number was soon increased to 25, the present capacity of the institution. Care and treatment are entirely free. The annual meeting of the United Hebrew Charities of the city of New York was held October 29, and the report showed that during the year ending September 30, the executive committee had acted upon 2,615 new applications for aid, and 2,377 cases for re-investigation. The physicians connected with the society made 1,927 visits and gave 2,252 prescriptions.

—Prof. Samuel G. Armor, Dean of the Faculty of the Long Island Hospital Medical College, died October 27, at his home in Brooklyn. He had not been well for some time, but was seriously ill for only a few days. Dr. Armor became connected with the Long Island Hospital School, as Professor of Thera-

peutics, Materia Medica, and General Pathology, in 1866, and the next year he succeeded Dr. Austin Flint, who had resigned, in the chair of Practice of Medicine and Clinical Medicine. During his residence in Brooklyn he contributed frequently to current medical literature, and built up a large private practice; while he was universally esteemed and respected in the community. Before coming to the Long Island Hospital school, Dr. Armor had gained a reputation as a medical teacher through connection with Western medical colleges for nearly twenty years. He practiced at Rockford, Ill., for three years, beginning with 1844, and was then invited to deliver a course of lectures at the Rush Medical College of Chicago. In 1848, he became Professor of Natural Sciences at Cleveland University. In 1853 he became Professor of Physiology and Pathology in Ohio Medical College at Cincinnati, and three years afterwards he was called to the chair of Pathology and Clinical medicine in the Missouri Medical College (his Alma Mater), at St. Louis. He remained there until 1861, when he went to Detroit as Professor of the Institute of Medicine and Materia Medica in the University of Michigan, in which position he remained until 1866, when he was invited to Brooklyn.

## Miscellany.

### SMALL-POX IN MONTREAL.

THE hospital accommodations for small-pox patients are being constantly increased in Montreal, and are still inadequate. Hospital accommodation for eight hundred more patients has just been ordered by the Board of Health. The records of the Board show the existence at the present time of at least two thousand five hundred cases in the city. But it is believed that the actual number would be nearer twice that.

This is the seventh month of the epidemic, and the daily number of new cases continues very large. The law for compulsory vaccination is not enforced, but the Richelieu and Ontario Navigation Company, which has been a financial sufferer by the interference with travel, will have a mass celebrated in the Church of Notre Dame de Lourdes for the cessation of the epidemic.

### A CORPSE IS NOT PROPERTY.

THE *New York Herald* says that the Supreme Court of South Carolina has recently rendered an elaborate opinion on a question which appears to have been decided for the first time in that case. It was an action brought by an administrator against a railroad company to recover damages for the mutilation of a corpse, caused by the negligent running of a train over it. The referee found for the plaintiff, and fixed the damages at ten thousand dollars. The case went to the Supreme Court on the question whether "there is such property or interest in the dead body of a human being as to sustain an action for its wilful or negligent mutilation, and, if so, whether the right of action belongs to the administrator of the deceased."

The Court decides that, while the next of kin have

recognized rights touching the dead, there is no such property in a corpse as is claimed in this case. It says: "While the remains of the dead should be tenderly protected, their interment carefully guarded, the mutilation of their bodies and the disturbance of their sepulchre severely punished, and while all laws necessary to that end should be passed and strictly enforced, yet, even for this purpose, to make such remains the absolute property of any one in the sense of objective appropriation would be abhorrent to every impulse and feeling of our nature."

But this view, the Court proceeded to explain, does not apply to the clothes in which the body was clad, and the watch on it. These were articles of personal property to which the administrator had a legal claim, and as they were destroyed he was entitled to maintain an action for their value.

## Correspondence.

### INTRODUCTION OF ANIMAL VACCINATION INTO AMERICA BY DR. MARTIN.

MR. EDITOR.—One point in Dr. Waterman's letter should be made a little clearer. Dr. Ephraim Cutter's vaccination of cows to which he alludes, was not true animal vaccination at all, but simply retro-vaccination with humanized virus. It is proper that there should be no misunderstanding about this.

A word of personal explanation. I am not aware that my letter "slandered a competitor." I merely stated such facts (principally the sworn statements of Dr. Cutter himself) as seemed necessary to illustrate the position of the two regular physicians involved. That my statements are true is not disputed. That the facts are discreditable to the parties concerned, is no fault of mine. If Drs. Garceau and Waterman, in response to my inquiries, had told me "an honest tale, plainly told," I should never have troubled you with the matter. No expression in my letter to you can be tortured into an advertisement of myself. My sole object was to thoroughly expose, and explode once for all, a false statement, deliberately made, tending to impair the credit justly due to my father for an honorable professional achievement. This I have accomplished, and am content to leave the matter to the impartial verdict of the profession. Very respectfully,

STEPHEN C. MARTIN, M.D.

Boxbury, Oct. 30, 1885.

### DEATH FROM UNDELIVERED PLACENTA.— CASE OF MALPRACTICE.

NANTUCKET, October, 1885.

MR. EDITOR.—A case has recently been brought to my attention as "medical examiner," which may be of interest to the medical profession; it indicates the desirability of regulating the practice of medicine. I will submit extracts from the view and autopsy with a portion of the testimony of the witnesses and that of the accoucheur himself. I have been careful to exclude nothing which I believe to be of importance in the case in question.

On September 4, 1885, I was notified that Mrs. H. had recently been delivered of a dead child, and the mother dying soon after, it was the wish of the family of the deceased that an examination should be made to determine if possible the cause of death. Accordingly, accompanied by Dr. Harold Williams, of Boston, on September 5th, I repaired to the home of the deceased.

We found the body well nourished and free from marks of violence, saving two small punctures on the abdomen, which had been made by the trocar used in embalming.

The face and body were markedly anemic, nails bluish, no ecchymoses. Rigor mortis had supervened.

About eight inches of the umbilical cord protruded from the vulva. At my instance Dr. Williams, as an expert, delivered the placenta, which he found partly in the cervix, partly in the uterine cavity. The delivery of the placenta was easily accomplished and was followed by a large quantity of fluid blood and several large coagula.

The placenta, on careful inspection, was found to be free from all evidences of adhesions, and was entire.

From Mrs. M., mother of the deceased, I learned that Mrs. H. was a primipara, aged thirty-one years, of good health; that she was delivered at term. That the pains were first noticed about 4 P.M., September 1st. That C. D. Marsh, who delivered the deceased, arrived about 9 P.M. the same day. That Mrs. H. was delivered by forceps at 5.40 A.M., September 2d. That the child was alive at delivery but died. That C. D. Marsh made no satisfactory attempt to deliver the placenta. That C. D. Marsh left the house and came to the town of Nantucket, some six miles distant, within an hour after delivery. That there was much bleeding at the time of delivery and great pain. That C. D. Marsh did not return until about 3 P.M. of the same day. That when he did return he made no satisfactory attempt to deliver the placenta, although Mrs. H. had bled profusely during his absence. That C. D. Marsh assured the family that the woman was in no danger, and that there was no need of professional assistance, although the family desired a doctor's aid. That C. D. Marsh again left for the town of Nantucket about an hour later, the placenta still being undelivered, and the woman bleeding, and that he did not again return until about 9 A.M., September 3d. That Mrs. H. died about 11.30 P.M., September 2d, her death being preceded by bleeding, great pain, and convulsions. That Mrs. H. became very pale before she died.

I immediately reported these facts to the Hon. H. M. Knowlton, District Attorney, who advised an autopsy. Accordingly assisted by Dr. Williams, with Dr. Pitman and Wm. Lawrence, Esq., as witnesses, a careful autopsy was made.

The cerebral, thoracic and abdominal cavities were bloodless and normal in appearance on careful inspection; the uterus was large and flabby, unruptured, as was the vagina. On opening the uterus it was found to be empty, save one small clot about three-eighths of an inch in diameter and some small shreds of decidua reflexa. The placental surface was on the left side, extending from about one inch above the internal os into the upper third of the uterine cavity. Corpus luteum of pregnancy in right ovary. I might add, no blood was found in heart or lungs, and but a small amount of sanguine fluid in the thoracic cavity.

Our opinion as recorded was:—

"From these facts observed in the autopsy and view, we are of the opinion that death resulted from uterine hemorrhage. From the evidences gathered from this autopsy and the view preceding it, and from the statements of those who were present from the delivery to the death of H.—, we believe this hemorrhage resulted from the non-removal of the placenta, which neglect prevented uterine contraction, nature's means of arresting hemorrhage. And there has appeared to us no satisfactory reason why the placenta should not have been removed."

C. D. Marsh, the accoucheur, is an irregular practitioner of newspaper fame, his doings being recorded in the *Boston Globe and Police Gazette* in the year 1879. I believe. C. D. Marsh under oath deposed:—

That he used Codrnan & Shurtleff's pattern of forceps; that he attempted to complete the third stage of labor by pulling on the cord, and the placenta not yielding he was convinced there was hour-glass contraction; that he did not know the Credé method; that before he left he considered the woman in danger, but that with the traction already mentioned and the addition of stimulants, he did all that any physician could have done; that she had recovered from the shock of delivery, and that he left about 8 A.M.; that he returned about 2 P.M. the same day; that had he attempted to deliver the placenta it would have

brought on hemorrhage, and the woman was too weak to stand it.

"Q. What is the proper course when the placenta resists traction upon the cord? A. To cause a pressure on the abdomen over the womb, rubbing and blowing, let the patient blow, the physician holding on to the cord. Q. What supposing it does not then yield? A. Let it remain, as I did, that is the way physicians generally do. Q. How long? A. From one day to four days, and sometimes a week, and sometimes let it decay and come away."

That on the second visit he stayed about two and one-half hours and left the patient comfortable; that he resorted to the means already mentioned, and the placenta still remaining undelivered he returned to town, six miles distant, leaving orders that if anything happened to send for him.

"Q. Is it considered among physicians the proper thing

to leave a woman in the condition you left that woman, so that you could not be recalled in less than fifty-two minutes? A. I considered it so." When asked further questions he refused to criminate himself.

This evidence, together with the opinion of an eminent specialist, who said, after reading the view and autopsy: "I am compelled to state that in my opinion such neglect to deliver the afterbirth was either gross and criminal ignorance, or gross and criminal malpraxis"; and the opinions of Dr. Williams and myself, in which we reiterate the verdict given at the close of the autopsy, being laid before the Grand Jury, an indictment could not be found, and C. D. Marsh considers himself justified.

Is it not the duty of the Legislature to form such laws as will at least protect the ignorant from such malpraxis? Other States have done this long ago.

Yours respectfully, J. ALBAN KITE, M.D.

## REPORTED MORTALITY FOR THE WEEK ENDING OCTOBER 24, 1885.

Cities.	Estimated Population.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Population by State Census, of May 1st, 1885.

Deaths reported 1,190: under five years of age 501; principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrhoeal diseases) 272; consumption 247; lung diseases 126; diphtheria and croup 50; diarrhoeal diseases 70; typhoid fever 50; malarial fever 22; whooping-cough 11; scarlet fever 10; cerebro-spinal meningitis eight; erysipelas five; puerperal fever two; small-pox one; measles one; typhus fever one. From malarial fever, New York 10, Baltimore, nine, Philadelphia, Nashville, and Charleston one each. From whooping-cough, New York 10, Philadelphia one. From scarlet fever, New York five Philadelphia three, and Boston two. From cerebro-spinal meningitis, New York three, Philadelphia two, Providence, Worcester and Haverhill one each. From erysipelas, Baltimore three, New York two. From puerperal fever, Boston two. From typhus fever, New York one. From small-pox, New York one. From measles, New York one.

In 103 cities and towns of Massachusetts, with a population of 1,312,471 (population of the State 1,911,465), the total death-

rate for the week was 11.38 against 15.57 and 14.06 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,906,116, for the week ending October 31, the death-rate was 17.06. Deaths reported 3,007; infants under one year of age 797; acute diseases of the respiratory organs (London) 205; diarrhoea 126; whooping-cough 52; scarlet fever 19; measles 16; diphtheria 65; small-pox 26; diphtheria one seven.

The death-rates ranged from 12.3 in Bolton to 26.0 in Oldham; Birkenhead 12.9; Birmingham 14.6; Brighton 15.9; Hull 11.0; Leeds 18.5; Liverpool 23.5; London 10.0; Manchester 22.4; Nottingham 13.6; Sheffield 20.0; Sunderland 16.2.

In Edinburgh 11.8; Glasgow 18.7; Dublin 11.1.

For the week ending October 31, in the Swiss towns, there were 10 deaths from consumption, diarrhoeal diseases, 18, lung diseases 11, typhoid fever four, scarlet fever two, diphtheria and croup one, whooping-cough one, erysipelas one.

The death-rates were: at Geneva 15.7; Zurich 9.7; Basle 9.1; Berne 21.8.

The meteorological record for week ending October 24th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole of the United States Signal Corps:—

Week ending	Barometer.	Thermometer.		Relative Humidity.			Direction of Wind.			Velocity of Wind.		State of Weather. <sup>1</sup>			Rainfall.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM OCTOBER 24, 1885, TO OCTOBER 30, 1885.

HUNTINGTON, D. L., surgeon and major. Detailed on Board to inspect army and navy hospital buildings at Hot Springs, Ark. S. O. 245, A. G. O., October 24, 1885.

MCLDERBY, HENRY, surgeon and major. Granted leave of absence for four months from November 1, 1885. S. O. 246, A. G. O., October 28, 1885.

PATROL, J. H., assistant surgeon and captain. Appointed member of Board to meet at Fort Jackson and St. Philip, La., on November 5, 1885, to select a site for the new quarters for the ordinance sergeants at those posts. S. O. 230 Department East, October 28, 1885.

TOMLEY, G. H., assistant surgeon and captain. Granted leave of absence for two months, to take effect after the return from leave of absence of Surgeon J. C. Bailey (major). S. O. 87, Division of the Atlantic, October 24, 1885.

RAYMONS, C. C., assistant surgeon and first lieutenant. In charge of the Medical Director, Department of Arizona. S. O. 102, Department of Arizona, October 17, 1885.

EWING, C. B., assistant surgeon and first lieutenant (Fort Leavenworth, Kan.). To accompany congressional committee, of which Hon. W. S. Holman is chairman, in its visit and inspection through Indian Territory. S. O. 160, Department of Missouri, October 23, 1885.

EVES, F. J., assistant surgeon and first lieutenant. Relieved from temporary duty at Fort Laramie, Wyo., and ordered to Fort D. A. Russell, Wyo. S. O. 106, Department of Platte, October 22, 1885.

MORRIS, E. R., assistant surgeon and first lieutenant (recently appointed). Assigned to duty at Fort Bayard, N. M. He will continue on detached service under orders of district commander. S. O. 160, Department Missouri, October 23, 1885.

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE FOR THE TWO WEEKS ENDING OCTOBER 24, 1885.

LONG, W. H., surgeon. To proceed to Detroit, Mich., and assume charge of the service, October 23, 1885.

ALLEN, H. W. To proceed to Albany, N. Y., on special duty, October 11, 1885.

WILLIAMS, L. L., assistant surgeon. Relieved from duty at Norfolk, Va., to proceed to Washington, D.C., for temporary duty, October 20, 1885.

#### SOCIETY NOTICES.

MASSACHUSETTS MEDICAL SOCIETY, SUFFOLK DISTRICT. The section for Clinical Medicine, Pathology, and Hygiene will meet at 19 Boylston Place, on Wednesday, November 11, at 7.15 o'clock. Papers: Dr. S. C. Martin, of Roxbury, "The Inoculation, Propagation and Preservation of the Virus of Animal Vaccine, with a Description of the Appearance of Kimo-pox, and Demonstration of the Vaccine Vesicle upon Horses." Dr. E. W. Churchill, of Boston, "The Specific and Infectious Character of Tuberculosis, with Exhibition of the Bacilli of Tuberculosis, and those of Malignant Postule anthracis." Dr. Vincent V. Bowditch, "A Case of Phthisis with numerous Bacilli, Complete Arrest of Disease."

F. E. KNIGHT, Chairman.  
ALBERT N. BLOOMFIELD, Secretary, 138 Boylston St.

BOSTON GYNÆCOLOGICAL SOCIETY. — The next regular meeting of the Gynecological Society of Boston will be held at the Medical Library Rooms, No. 19 Boylston Place, November 12th, at 4 o'clock, P. M. Papers: "The Relation of Certain Bacteria to Puerperal Septic Processes," by E. W. Cushing, M.D.; the discussion will be opened by H. O. Marcy, M.D. A short paper on "Natural Constipation in Women: Its Causes and Effects," by H. J. Harriman, M.D.

H. J. HARRIMAN, M.D., Secretary.

Boston, November 2, 1885.

#### A NEW SOURCE OF CERTIFIED WET-NURSES IN BOSTON.

OUR BOSTON readers will be glad to learn that mutual arrangements have been entered into by the Directory for Nurses and the West End Nursery with the object of properly furnishing good wet-nurses. The Lying-In Hospital has hitherto been the only medical source of supply, so to speak, for this important need. The Directory for Nurses has kept a list of wet-nurses, but has never undertaken to assume any responsibility as to the qualifications of the women offered; leaving no means of keeping them under observation. The good work of the West End Nursery has been so unobtrusive that it will doubtless be news to many that this institution keeps wet-nurses as inmates, and is ready to part with them to private individuals requiring the services of such persons. While in the Nursery the women are, of course, under constant and skilled supervision by physicians and nurses, and ample opportunity is afforded to test their qualifications.

It is hoped that physicians will send the names of women desirous of taking a place as wet-nurse to either the Directory for Nurses, 19 Boylston Place, or to Dr. Haven, West End, 37 Blossom Street. The nursery will admit suitable women either with or without their babies, and will undertake in cases where it has furnished a wet-nurse to change her in case her milk does not prove satisfactory.

#### BOOKS AND PAMPHLETS RECEIVED.

The Essentials of Histology, Descriptive and Practical. For the Use of Students. By E. A. Schäfer, F.R.S. Philadelphia: Lea Brothers & Co. 1885.

Milk Analysis and Infant Feeding. A Practical Treatise on the Examination of Human and Cows' Milk, Cream, Condensed Milk, etc., and Directions as to the Diet of Young Infants. By Arthur V. Meigs, M.D. Philadelphia: P. Blakiston, Son & Co. 1885.

Forty-Fourth Annual Announcement of the St. Louis Medical College. Winter Session, 1885-86.

Moisture and Dryness, or, the Analysis of Atmospheric Humidity in the United States. By Charles Denton, A.M., M.D., Denver, Chicago: 1885.

The External Therapeutics of Pulmonary Consumption. Third Paper by Thomas J. May, M.D., of Philadelphia. (From Medical News, August 22, 1885).

Note on the Use of Cocaine in Hay Fever. By Roberts Bartholow, M.D., L.L.D.

Von Ziemssen's Handbook of General Therapeutics. In Seven Volumes. Vol. III, Respiratory Therapeutics. By Prof. M. J. Gertel, M.D., of Munich. New York: Wm. Wood & Co. 1885.

Lectures on the Principles of House Drainage. Delivered before the Suffolk District Medical Society (section for Clinical Medicine, Pathology and Hygiene) and the Boston Society of Architects, at the Massachusetts Institute of Technology. By J. Pickering Putnam, Architect. Boston: Ticknor & Co. 1886.

## Lecture.

### LOCOMOTOR ATAXIA—ANYOTROPHIC LATERAL SCLEROSIS—LATERAL SCLEROSIS.

A CLINICAL LECTURE DELIVERED AT THE HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

BY H. C. WOOD, M.D., LL. D.,

*Professor of Materia Medica and Therapeutics and of Diseases of the Nervous System in the University of Pennsylvania.*

GENTLEMEN, this patient comes to us with the statement that every two or three weeks, or sometimes at longer intervals, he has frightful attacks of abdominal pain accompanied with vomiting. Under these circumstances, attention is naturally directed to the condition of the stomach. We learn that these attacks are not provoked by any error in diet, that they are apparently spontaneous, and that between the attacks there are no symptoms of dyspepsia or indigestion. The attacks are exceedingly violent. The patient came to the hospital two weeks ago. When I first saw him, he appeared to be suffering from no severe symptoms. A day or two later, I found him in bed, groaning and moaning as though in agony. There was frequent vomiting of mucus tinged with bile, or of a liquid so thin as scarcely to be called mucus. These attacks of pain with persistent vomiting lasted three or four days and kept the man from sleeping, in spite of the free use of opium. Such attacks are evidently not dependent on irritation of the mucous membrane of the stomach.

The pain would suggest the passage of gall stones. Careful examination, however, shows that the pain lacks the sudden cessation which is characteristic of biliary colic. It is a steady, unbearable pain, lasting for hours and days and unaccompanied with jaundice, disturbed digestion, or any other manifestation of the passage of biliary calculi. You will call to mind the case of the woman with attacks of pain, similar to these, occurring in the rectum, which I showed you last week. When you have brought to your notice a case of horrible, recurring, violent, unaccountable pain, remember the possibility of its being one form of crisis occurring in locomotor ataxia. Sometimes these paroxysms of intense, shooting, darting, tearing, boring pain attacks the genital organs.

When I found this man sitting at his bedside, my attention was at once directed to his pupils. I found that they were very small, in other words, he had a distinctly myotic or contracted pupil. When I shut off the light with my hand, I found that the pupil did not dilate. It was, indeed, insensible to light. I then tried the pupillary reflex, but there was no dilatation of the pupil produced by pinching the skin of the neck. Then I asked him to look at my finger held close to his face and a moment later to look at a distant object, and found that the pupil which was immovable to light, and responded not to peripheral irritation, reacted normally to the movements of accommodation. Our patient has, therefore, that comparatively rare pupil known as the Argyle Robinson pupil, because first described by that gentleman.

Before going further with this case, I wish to say a few words in regard to conditions of the pupil as seen in nervous affections. We have as the afferent nerve, so to speak, going from the eye to the centre within the brain, the optic nerve. We have two centres, connected as motor centres with the pupil, the oculo-motor centre and the spinal dilating centre, situated high

in the neck. What happens when a person's neck is pinched? An impulse is sent through the sensitive nerves which reaches the cervical centres, lying in the upper part of the spinal cord. As a result, there goes out from the cervical sympathetic ganglia, an impulse causing dilatation of the pupil.

Again, the pupil contracts with exposure to light, and dilates when the light is withdrawn. This is especially accomplished through the oculo-motor centres. The optic nerve is the afferent nerve. Its fibres run through certain centres in the neighborhood of the thalamus opticus and then pass down to the corpora quadrigemina and oculo-motor centre. As a result of exposure to light, there is oculo-motor stimulation and the pupil contracts.

Then as to the movement of accommodation. When a near object is looked at, the eyes are brought convergent as to their axes, and at the same time, the pupil contracts and the shape of the lens is altered for the purposes of distinct vision. These are so-called consensual or associated movements, that is, movements which habit or the original construction of the nervous system has brought about as always being performed together. They apparently take place through the oculo-motor centre. An impulse from the upper cortical region of the brain is sent down to the oculo-motor centre for the act of accommodation, and the centre sends out an impulse which contracts the pupil, and at the same time, converges the eyes.

Besides these various movements of the pupil, there are others associated with emotional conditions, but we have been unable to study these in this case.

In the Argyle Robinson pupil, there is want of response to light and to reflex irritation from the skin, but the pupil does respond to alterations of accommodation. Wherever this pupil is found, there is almost of necessity serious organic nervous trouble, and the probabilities are always in favor of the idea that the patient is suffering from locomotor ataxia. The Argyle Robinson pupil has, however, been found in a certain number of cases of general paralysis of the insane, and perhaps, in a few other diseases, but it marks especially the presence of locomotor ataxia. Where in any given case, as here, there exists violent gastric crises, along with the presence of the Argyle Robinson pupil, you have even without further examination, sufficient grounds for the diagnosis of locomotor ataxia.

The explanation of this peculiar condition of the pupil is not difficult. We know that the optic or afferent nerve is perfect because the patient sees. There is no evidence of paralysis of the oculo-motor nerve and the pupil is contracted. Supposing the man to be suffering with locomotor ataxia, it is plain that the reason why there is no response to light is that the fibres which connect the optic centre with the oculo-motor centre are involved in the diseased structures.

There is interruption of the pathway and there can be no passage of the impulse from the centre of the optic nerve to the oculo-motor centre. The reason that the pupil does not respond to peripheral irritation is because the sensitive nerve connected with the upper spinal region is also involved in its passage through the cord. You will remember that in locomotor ataxia, there is a chronic inflammation and atrophy or hardening of the posterior column of the spinal cord, and hence these sensitive fibres are cramped and squeezed and their function abolished. When the skin is irritated, no impulse reaches the centre. It is interest-

ing to observe in connection with the gastric crises, these other signs that the disease is high up in the spinal cord, even in the medulla, for the medulla, although placed within the skull for purposes of protection is nothing more than the upper part of the spinal cord.

When the man is examined further, other evidences of locomotor ataxia are found. In the first place, he has lost the patella reflex. He has darting and shooting pains through the legs, unaccompanied with soreness, or with pain on motion. Remember that bilateral, darting shooting pains, without soreness and without pain on motion, are in nine cases out of ten, if they are persistent and not due to gout, the result of locomotor ataxia. When with this there is loss of the patella reflex, the diagnosis is almost positive. I have also found some disorder of coordination in this case. The man has a somewhat ataxic gait. He walks with the feet spread wide apart so as to give a firm base of support. The movement of the legs are irregular. With some difficulty he can stand on both legs with the eyes shut, but is unable to stand on one foot with the eyes shut.

We are therefore able in this case to arrive at a positive diagnosis of locomotor ataxia.

Leaving this case for the present, let me briefly call attention to the various forms of local inflammation of the spinal cord with which we meet in practice. In the so-called system diseases of the cord, the sclerosis or chronic inflammations involve certain tracts of the cord, running up and down, but do not invade widely scattered foci. In the centre of the cord is the gray matter. Then we have the lateral tracts. In the centre of the anterior portion of the cord is a small tract which corresponds to these lateral tracts physiologically. Then we have the posterior median columns or the columns of Goll. So far as system diseases are concerned, we know of two sclerosis especially, which produce definite symptoms. In the first place the posterior region may be involved, especially the region where the posterior nerve roots emerge, constituting *locomotor ataxia*. In the second place, the lateral columns of the cord may be affected, constituting *lateral sclerosis*. There are one or two cases in which the symptoms have been said to have been due to sclerosis confined to the columns of Goll. This is, however, rare, and I have never met with such a case. In the anterior portion of the gray matter there are certain groups of large cells. These are the motor cells whose function it is to convey the nervous impulses which shall cause contraction of the muscle, and it is also their function to preserve the nutrition of the muscle. When a muscle is cut loose from these cells it wastes and its electrical reactions change. When this portion is diseased, we have, if the affection is acute, infantile paralysis or acute muscular atrophy; if it is chronic, we have progressive muscular atrophy. When in spinal affection, there is rapid wasting of the muscles and rapid changes in the electrical reactions, there is disease of these cells; whatever else may be present in the spinal cord these cells are involved.

There is an affection of the spinal cord, in which there is disease of the lateral columns associated with disease of these motor cells. This is known as *amyotrophic lateral sclerosis*.

In the consideration of the case before us, I have called attention to most of the symptoms of locomotor ataxia. They are disorders of locomotion and coordi-

nation and pain without loss of motor power or wasting of the muscles.

Let me now call attention to this second case which represents another form of spinal affection, namely, lateral sclerosis. The symptoms of locomotor ataxia are sensory and afferent. The lack of the power of coordination is due to the failure of afferent impulses to reach the brain. In lateral sclerosis, the symptoms are disorders of motion, but not of nutrition of the muscle, nor of sensation. There is no wasting of the muscle and no lack of coordinating power. There is simply disorder of the motor function of the muscle. These are chiefly the result of irritation, so that there is more or less permanent spastic muscular contraction. With this there is excitability of the reflexes with a certain amount of loss of power, because whilst the fibres are irritated, there is also interference with the passage of currents down from above.

This case exhibits the symptoms of lateral sclerosis. Although I lift the leg and support it at the thigh, there is no bending at the knee, and it requires considerable force to flex the leg. Tapping the tendon of the patella, I find that the patellar reflex is abnormally increased. I cannot at this time develop ankle-clonus, although it has been noted in this case. There is, then, excessive rigidity, increased reflex activity, and, in addition, a peculiar gait. When the disease is fully formed, the gait is characteristic. The patient cannot get his toes from the floor, owing to the spasm of the calf muscles. Examining the legs, no muscular wasting is found. The electrical reactions are normal. The arms are sometimes affected in lateral sclerosis, but in this patient the stiffness is very slight at the arm. There is, however, great loss of power in the arms. On exploring the arms, fibrillary contractions are noted as abundant. These are never seen in pure lateral sclerosis. Moreover, there is great wasting of the shoulder and arm muscles. These symptoms, we are told, came on gradually, they are evidently due to disease of the motor or anterior cells of the grey matter of the cord, and we have an instance of the chronic spinal disease, known as *amyotrophic lateral sclerosis*.

Turning now to the third patient, we find the following history. This girl is twenty-six years of age. She was in good health until three and a half years ago, when she developed the symptoms with which she now suffers. The affection has come on gradually. There was, she stated, at one time partial loss of power in the left arm and leg, and she was unable to work for four weeks. She then obtained an easy place and returned to work.

You observe the same stiffness of the legs, seen in the previous case. When I raise the thigh from the bed, there is no flexion at the knee. The muscles of the calf are contracted. The patellar reflex is increased. There is some rigidity of the arms, most marked on the left side.

We have then, in this case, either lateral sclerosis or something simulating it. There is an affection known as hysterical contracture in which there is loss of power, with heightened reflex activity, rigidity, or more or less permanent contraction of the muscles, a disease which very closely simulates lateral sclerosis, and in some cases it is almost impossible to make the diagnosis. Two years ago I had a case in the Philadelphia Hospital which well illustrates the difficulty in diagnosis. This woman suffered with Pott's disease of the vertebrae which had produced angular curvature.

It is not uncommon to have secondary sclerosis following the transverse myelitis of this affection. With a pronounced history of disease of the vertebrae, there were the typical symptoms of lateral sclerosis and an almost entire absence of hysterical indications. The diagnosis of lateral sclerosis was made. On one occasion, she was given some powders of bismuth for a slight derangement of the stomach, and she began to rapidly improve, so that in a few days, instead of being confined to a rolling chair, she was able to walk about. That was largely a case of hysterical contractures.

This woman before us is not distinctly hysterical. If in a decidedly hysterical patient you have symptoms like these, especially if they have developed suddenly, the probabilities are that you are dealing with a case of hysterical contracture. Although this patient is somewhat nervous, she is not distinctly hysterical. The disease has come on slowly. Hysterical contractures are more apt to come on suddenly, but not necessarily so. This woman has another symptom which I believe is characteristic of organic disease, and at present, I should always make the diagnosis when I found it distinctly present. During the past two months she has complained of having the feeling of a bandage around the waist. This she spoke of herself. Of course if you ask an hysterical patient if she has a band-like feeling around the waist, she will be very apt to say that she has, when she had never dreamt of it. Another point I wish to allude to, and that is, that chronic nervous diseases, especially in women, are often associated with hysteria. If any one of us were shut in a room for months and months, over-shadowed by a great cloud of approaching troubles, it is probable that we would develop hysterical symptoms. The point is always to be borne in mind, that underlying the hysterical manifestations, there may be a real organic trouble.

There is in this case, a slight inequality of the pupils. Everything, therefore, points to the existence of lateral sclerosis and the prognosis is unfavorable. We should, however, not pronounce a too positive prognosis, but should leave a way of escape in case the condition should prove to be largely hysterical.

### A CASE OF INFANTICIDE.<sup>1</sup>

BY W. H. FAYLOR, M.D., SEN. HENRIETTA, *Medical Examiner.*

M. R., aged a few years over thirty, gave birth to her fourth illegitimate child at some time during the night succeeding April 21st, 1881. She was employed as a domestic in a gentleman's family, and as she did not appear at her customary duties on the morning of April 22d, search was instituted, and she was found in bed suffering from the effects of her delivery. The physician to the poor being summoned, found a dead child lying upon the floor, closely wrapped in a shawl, together with the results and debris of the labor. Not being satisfied that the child was still-born he referred the case to me, and gave a very full account of the appearances of the room, mother, and child, which caused in his mind the suspicion that all was not as it should be. Upon arrival at the house I found the woman in bed in a room at

the farther end of the attic from the stairway, which stairway was shut off from the story below by a door. She occupied this attic alone, and had neither medical nor other attendance during her labor.

Upon the floor in front of the bed, and a foot or a foot and a half from it, was a waterproof overgarment of india rubber, the edges of which had been carefully turned over to make a sort of trough three feet by two perhaps. Upon this garment was a chamber-vessel filled completely with bloody fluid and a placenta with membranes attached. Four inches of the umbilical cord remained upon the placenta, and the extremity of the cord was ragged. Beside the chamber-vessel the garment had upon it the body of a new-born child (wrapped in a red and black checked shawl), a blue flannel skirt, and a large quantity of human feces, meconium and bloody fluid.

The mother on being questioned concerning her labor, stated that she went to bed as usual on the night of the 21st, not expecting to be confined. At eleven o'clock, p.m., she had a desire to urinate, and rose to perform this act. Upon resuming the bed, she had a few slight pains not sufficient to prevent sleep. At midnight, as near as she could judge, she had a desire to stool, and, rising for the purpose, while in a squatting posture by the bed, she gave birth to her child, then fainted and fell to the floor. At one o'clock, a.m., she regained consciousness, and, throwing a shawl over the child, she went to bed, where she remained until found in the morning. She did not know how the cord became ruptured, or how the placenta came to be in the urinal, and the child upon the floor. She did not hear the child cry or manifest any sign of life.

Examination of the child's body revealed the following appearances. The body was well smeared with meconium, and a considerable quantity had escaped from the child. The face, hands and feet were cyanotic. The body was cold with hardly any rigor mortis. The portion of umbilical cord attached to the child was twenty-five inches long and had one turn about the child's neck, leaving a free end fifteen inches long. The extremity of the cord was ragged and bulbous, and had clot behind the incurved extremities of the vessels. The cord had not compressed the neck to leave any depression or mark, and could not have compressed it except by strong traction of the maternal end. A little whitish froth was noted about the left nostril. There was a slight erump succedaneum over the occiput and a little to the left. No marks of bodily injury were seen on inspection. The cavities of the body opening externally, contained no solids or fluids except what might naturally occupy them.

Autopsy showed a fat male child at term, twenty inches long and weighing seven and three-quarters pounds. Both testicles were in the scrotum, and the nails had grown to the ends of the fingers. No fluids escaped on inverting the child, and none were found in the respiratory passages.

On opening the body, the diaphragm was found at the level of the sixth rib. The lungs removed with the heart and thymus gland, floated high above the surface of water. Sections of all parts of the lungs floated after being subjected to heavy pressure. Sections made from the edges of the lungs with the freezing microtome by my friend, Dr. Wm. N. Switt, who kindly assisted me, showed the air-cells to be everywhere fully dilated. The lungs were rosy red anteriorly, darker posteriorly. They contained much dark

<sup>1</sup> Read before the Massachusetts Medical-Legal Society.

blood, and were somewhat congested centrally, and posteriorly. The cavities of the heart, particularly the right ventricle, contained a good deal of dark fluid blood, as did also the entire venous system. The liver was much congested, dark blood flowing copiously on section. The kidneys were much congested, but otherwise were normal. No uric acid infarction was observed on gross inspection. The stomach contained a drachm of yellowish fluid and some air. Air was seen in the intestines as far down as the transverse colon. The urinary bladder contained a few drops of fluid. The brain was much congested but otherwise was normal, and the same remark will apply to the upper two inches of the spinal cord.

It is certain that the child did not die of hemorrhage. It is equally certain that it was a well-formed and normal child capable of carrying on its existence with ordinary care. No marks of injury to cause death were anywhere apparent. The appearances were those of death from suffocation, and an opinion was given to the proper legal officers that the child came to its death from suffocation, exposure, and neglect. At the inquest the justice of the district court held the woman to appear before the grand jury for murder of her child. Upon taking testimony, the grand jury found no bill against her.

Certain points of interest appear in this case which it may be profitable to discuss. First, as to the truth of the woman's story. It is evident from preparations made that she *did* know of approaching labor, and the caput succedaneum shows that the labor was not quite tumultuous. She could have summoned aid had she been so disposed. How came the child upon the floor and the placenta in the vessel? How was the cord ruptured? If the woman fainted immediately after extrusion of the child, she must have fallen into the surrounding filth. Nothing was found upon her clothing but a little ordinary lochia discharge. The extraordinary movement of the placenta is hardly consistent with the statement of fainting. Upon inquiry, the woman stated that at time of delivery, her buttocks were not more than a foot from the floor. The cord had a free end of fifteen inches in length, and the child weighed only seven and three-quarters pounds. With regard to the sustaining power of the cord, the only reliable statement at my hand is that of Robin, quoted by A. Flint, Jr., who puts it at ten to twelve pounds. Taylor says nothing definite about it, and Tidy refers to the experiments of Nægrier and others as being inconclusive, without giving any definite views of his own. I wished to make some experiments in this direction before presenting this case, but have not been able to do enough reliable work as yet to warrant notice. If members feel so disposed, I would suggest that a good spring-balance would occupy but little room in the obstetric bag, and any information sent me will be gratefully received and acknowledged in a subsequent paper. A broad tape might be used to attach the fetal end of the cord to the hook of the balance, and the balance being fixed, traction upon the cord to the point of rupture be made. The index of the balance could be made self-registering in many ways, which readily suggest themselves. It is almost superfluous to say that such observations should be made immediately after birth of the child, as the changes going on in the cord may make delayed experimentation useless. Reports giving the length of time after delivery, the weight required to break the cord,

and the part of the cord broken, would be of value in the present uncertainty on the subject. Where possible, the effect of weight combined with falling from a known distance would, if noted, be valuable, but naturally such experiments would be more subject to error than simple ones.

How long did the child live? Tardieu, quoted by Tidy, says that the presence of air in the alimentary canal indicates an existence of ten or fifteen minutes, the length of time being in proportion to the depth to which the air has penetrated. In this case, the opinion was given that the child lived some minutes. It is not probable that in this case the child breathed in the maternal passages, as the presentation was of the vertex, and the labor was not delayed.

Could the child have been strangled by the turn of the cord about its neck? The turn was what is commonly called a half-hitch, necessarily exercising no constricting power in absence of a strong pull upon the maternal end. The cord was of unusual length (twenty-nine inches) and, as has been before noticed, the position of the mother would preclude the possibility of strangulation after birth. With regard to strangulation before birth, it is evident that the full dilatation of the lungs and the air in the alimentary canal would have been lacking. Taylor very justly says, that the term strangulation should not apply to those cases where by constriction or knotting of the cord during labor the maternal oxygen is withheld from the fetus. Though the child dies in the same manner as in strangulation, still the term is better limited to subjects which have breathed. My view of this case is that the woman knew of her approaching labor, that she ruptured the cord by pulling upon it after the child was born and before the placenta was delivered, that she removed the placenta and placed it in the chamber-vessel, and, rolling the child snugly in the shawl to avoid warning the family of what had taken place—if for no more unworthy purpose—she went to bed, leaving the child to succumb, which it soon did by suffocation. How much exposure may have favored death it is difficult to say. The temperature of the outside air was about 33° F. during the night. It is hardly reasonable to suppose that the mother was ignorant of the care necessary to be given to a neonatus, as she had had three children previously.

#### ON THE ABUSES CONNECTED WITH GRATUITOUS MEDICAL TREATMENT.

BY HASKET DEBRY, M.D.

It may be taken as a maxim that gratuitous medical attendance is to be exercised with discrimination. The obtaining from their profession a means of support for themselves and their families will always be a necessity to the great majority of practitioners. The difficulties in the way of this would evidently be enhanced if they were forced to compete with those whose desire of increasing their clientele led them to reduce their fees far below the usual standard; or whose private means enabled them to practice without remuneration, for the sake either of extending their knowledge or spreading their reputation.

Every physician, therefore, owes it to his brethren to limit his gratuitous practice to certain classes of people. It is his right and duty thus to treat members

of his own profession, unless they have reasons for desiring the contrary, and his privilege to extend his unrequited services to his immediate relatives, and perhaps even to a few most intimate friends. And, over and above this, he expects throughout his life, and especially if connected with any hospital or public clinic, to constantly prescribe for a large number of the poor.

The multitude of those classing themselves under this head, and applying for free medical attendance, is increasing at a considerable rate; and even more than keeps pace with the clinics, public and private, that now open their doors. In Boston, the Eye and Ear Infirmary alone treated 1,911 out-patients in 1852, 3,580 in 1867, 11,027 in 1884. In the same year the total number applying at this institution, the Massachusetts General Hospital, City Hospital, Carney Hospital, and Boston Dispensary was 56,908. When we add to this the number treated at their homes by medical men connected with the above charities, as well as those applying at other clinics scattered through the city, it is evident that these figures would be largely added to. And, considering the population of Boston and the surrounding country, the question naturally arises as to whether the percentage of those receiving free medical and surgical attendance is not abnormally large, and whether a greater degree of discrimination ought not to be exercised by those prescribing for the poor.

I am well aware that this is a threadbare theme on which to submit a paper to this Society, and that much has already been said and written on this subject by those more competent than myself to discuss it intelligently. I venture, however, to again bring it forward, believing as I do that it has thus far largely fallen into the wrong hands, and that it is not for the directors and trustees of our public institutions, whose management of their finances may be admirable, but whose knowledge of their medical and surgical workings might be superficial, to deal theoretically with so grave a question, and frame regulations for the government of an out-patient Utopia. It belongs to the profession, who devote their skill, energies and time to the extension of this relief, to decide on the cases to which it is applicable, as well as to adopt practical measures for the restriction of its abuse. No principle is more false than the one that a physician should be compelled, at the bidding of the lay directors of any medical institution, to treat gratuitously any patient from whom he might with justice accept a fee, had he applied at his private office rather than at the hospital.

The throng requesting medical aid at the out-door department of any public institution may ordinarily be classed as follows:—

*First.* There are those able and willing to pay for treatment. They are attracted to the institution by its established reputation, as well as by reports of the skill of its staff. They neither expect or desire to be treated gratuitously.

*Second.* Those able to pay a fee less than the ordinary one; but anxious to have what they consider the best talent brought to bear on their cases, and deterred from consulting the same privately by a fear of the expense.

*Third.* Those able to pay but unwilling so to do; hoping to steal an opinion and pass unnoticed among the crowd.

*Fourth.* The deserving poor.

The problem for solution is how to deal with these various classes; to define those really entitled to relief, as well as to arrive at a practical plan for their ready selection. My own solution I offer with all modesty. It is based on twenty years' experience at the Eye Infirmary. Here we have at present an out-patient department of over eleven thousand, recruited from all over New England, and more largely perhaps composed of our native population than would be the case among those applying from the city proper.

The first class, or those able and willing to pay, find placards hung at conspicuous points in the waiting-room, informing all comers that the institution is a public charity, that "it is designed wholly for the poor and needy, under no circumstances for those who are not proper subjects for charitable treatment." These notices prove entirely sufficient and bring about the withdrawal of such people as those above described.

Those able to offer a fee less in amount than that ordinarily demanded are more difficult to deal with. They at once admit, on being questioned, that they do not care for charitable treatment, and expect to pay something. But they have been informed that they will get "the best advice" here; or they assume that professional ability depends on the length of time a man has been in practice, but fear that a private consultation with the older members of the profession will be beyond their means. It is hardly possible to lay down a hard and fast rule applying to all such cases, and yet I believe that this class should, in the great majority of instances, be refused treatment. An honest statement of their circumstances to the private practitioner will almost invariably result in an arrangement by which the fee will be proportioned to their means. And, what is of much importance, the withdrawal of this class of patients from the profession at large, works a distinct injury to the struggling beginner, whose time has not yet become sufficiently valuable to oblige him to always insist on a full honorarium and whose possible absence of private means compels his entire dependence on his professional income; an income largely recruited, during the earlier part of his practice, by the smaller fees derived from patients of relatively humble means. Wealthy hospitals and well-appointed clinics, by absorbing such cases, render the upward path of the medical beginner more difficult year by year.

This whole question of fees, large and small, is both delicate and distasteful. Its discussion lays us open to the imputation of mercenary motives; its casuistry is objected to as unworthy the disciples of a great and beneficent science. But if the laborer is worthy of his hire, if those who serve the altar are to live by the altar, the devoted physician has surely a right to a decent support from the community whose well-being is intrusted to his care, and to whose service he often sacrifices health, and sometimes life itself. Nor can he regard the matter from the airy height of disinterested benevolence, but must keep his books and collect his dues on the same business principles that govern his relations with his own creditors.

The above classes being eliminated, there remain those seeking to obtain advice or treatment by fraud, and those legitimately entitled to both. How to distinguish between them, and in the case of the latter, how to determine that precise degree of absence of worldly possessions that entitles one to free medical treatment, is the great out-patient problem.

The ingenuity of those who seek to disguise their resources must have been experienced to be credited. We were once surprised by a handsome legacy from the estate of an old lady, who had for weeks enjoyed the hospitality of the Infirmary and there been relieved of a cataract: an excellent thing for the institution itself, but not calculated to raise the spirits of the surgeon originally in charge of the case. Another free patient, treated for the same disease, was afterwards discovered to have been the mayor of a New England town, and a large real-estate owner there at the time of the operation. "I prefer to see you at your office, Doctor," said a young man to me once, "as I get more of your time. But I suppose I might go to the infirmary as uncle does." "Is your uncle a very poor man?" I asked. "O, Uncle owns a factory." "But how does he manage to pass at the infirmary?" "Uncle's sly," said the youth, with an exquisite enjoyment of the fact: "he puts on old clothes and dirties his hands, every time he comes down." A well-known lawyer of this city once emerged from the waiting-room, and sat down in the patient's chair. On being remonstrated with for attempting to impose himself on a charity, he coolly informed me that all he wanted was an examination and opinion, having obtained which he proposed to place himself under private treatment outside. He had evidently thought he would escape recognition. A well-to-do merchant, being similarly detected, informed us that he had been a tax-payer for forty years, and demanded treatment as a right. Finally, one day, a very respectable and well-dressed lady from New Hampshire presented herself for treatment, and disclaiming poverty, was refused an examination. The next patient, evidently in good circumstances, hailed from the same place. So did the four succeeding, all unfit cases for relief. At last it transpired that we were dealing with the members of a cheap excursion, where one of the attractions offered by the enterprising agent had been a free call at the Eye Infirmary.

Various have been the expedients proposed for the sifting out of these cases justly entitled to free relief, and numerous the rules laid down for the purpose of defining them. It has been sought to draw the line at a certain sum earned weekly; all in receipt of smaller wages being accepted, the rest rejected. The absurdity of such a test is borne on its face. A weekly income, large for a single man, may mean absolute want to one with a family dependent on him; while certain occupations involve an expenditure for personal appearance that leaves very little of the modest salary for other than the most urgent wants, even to the man who has but himself to care for. Attendant circumstances are therefore as important as the gross amount of wages earned. Again, it has been sought to test the good faith of applicants by an adaptation of the detective system, employing a trained official to cross-examine them in the outset, and ultimately to investigate doubtful cases at their homes. Were the city poor alone to be considered, such a system might not be without its advantages, but it is evidently inapplicable to a clinique whose material is collected over a wide territory. But little more than half our Infirmary patients are residents of Boston, many of the remainder coming from distant parts of New England. Information might, it is true, be obtained from their town authorities, but the necessary correspondence, besides involving us in the expense of an increased

clerical force, would bring upon the really deserving poor a publicity both unpleasant and unmerited. This would be especially true in the smaller towns.

Passing over other plans, the solution of the whole matter seems to me so simple that I mention it with diffidence. It is but to accept the principle that the out-patient department is for the benefit of those whose lack of means would prevent their obtaining relief elsewhere, and to leave the application of this principle to the physician in attendance. He alone has the responsibility of examination and treatment, he alone should have the privilege of deciding whether his services are well bestowed. If charged with the direction of an important clinique, he is ordinarily an older man than any of his subordinates, has a larger experience of human nature, and, from previous work among the poor, has acquired a more intimate knowledge of their modes of thought and action. Bound by no arbitrary and inflexible rule, he will be able to judge humanely and act promptly. We shall at once be met by the objection that police work of this description is not only distasteful, but no part of the duty of a medical man. A little reflection will, however, show that it can never be very onerous. About the great majority of patients that throng the waiting-rooms of our hospitals, there can be no manner of doubt. And when anything in the dress, manner, or statement of the individual causes hesitancy to be felt, a few questions, put with tact and kindness, will readily resolve the matter; or if doubt should still be felt, the applicant for aid should certainly receive its benefit. It is not pretended that the medical examiner will be infallible, but we claim that fewer mistakes will be made by him than by any other to whom this task may be delegated, and that he should not be hampered by a set of arbitrary rules, in the framing of which he has had no voice, and from the principle of which he may even dissent.

We would not, however, give him unlimited powers. The claim is sometimes made that, for purposes of medical instruction, all should be fish that comes to the net, that valuable material for demonstration is on no account to be thrown away, and that a rare and interesting form of disease may be retained and treated, even though the patient belongs to the better classes. But the end justifies the means as little in medicine as in theology. Such a patient has no claim whatever on an institution endowed for the benefit of the poor. His withdrawal from the ranks of those on whom the profession at large depends for support, works a distinct wrong to the private practitioner, into whose hands he would otherwise fall. If the chief of the clinique elects to utilize in that way his own material, if he conscientiously diverts patients from his office to the hospital, and forgoes his just remuneration for the benefit of his class, all honor to him who thus immolates himself on the altar of science. But he has no right to assume that his professional brethren are equally disinterested, or to aid the individual who is in fraudulent search of gratuitous treatment.

This abuse, however, sinks into insignificance by the side of one to which I wish, in closing, to call particular attention. It is the requirement, on the part of the lay-governing board of a hospital, that their professional staff shall attend and, if required, operate free of charge on any patient, whatever his means, who may choose to occupy a private room at the institution, and pay the rate of board demanded for the same. The charging a fee is, under these circumstances,

strictly prohibited; the invalid pays his twenty-five or fifty dollars a week, and receives in return the free attendance of the best medical and surgical talent that can be found in the community.

A case in point will show the practical working of this state of things. And I would call attention to the fact that what follows is a simple narrative of an actual occurrence. In a New England city, a surgeon, eminent for his skill, was consulted by a woman from the country, who had a tumor of the breast requiring removal. She was accompanied by her clergyman, who proceeded to make the necessary arrangements on her behalf, for the operation. After some inquiry into the patient's circumstances, a fee was named that she declared herself quite able to pay. A boarding-house was engaged, and the day fixed upon. The two left the office, congratulating themselves on having obtained the desired professional skill on terms that met with no objection. Two days later the clergyman appeared alone.

"Doctor," said he, "I am come to tell you that we will not have you perform the operation. You are not, however, to infer that we doubt your skill, or are dissatisfied with your fee of one hundred dollars, but Sister Blank has visited the So-and-So Hospital, and there learned that, by taking a room at twenty-five dollars a week, she can have the operation performed for nothing. She can readily find other uses for the money she would have paid you, and feels it to be her duty to save the amount."

So the matter ended. The surgeon lost his fee, the hospital got its board, and Sister Blank swindled the profession. Comment is here superfluous. We see the reputation, wealth and influence of a powerful institution pitted against the private practitioner, who naturally goes to the wall. And this state of things will continue until the profession takes a firm stand in its own defence, and enacts that its members, who serve a public charity without emolument, shall deny their gratuitous services to all save those who are really unable to meet a fair charge from their own resources.

#### RUPTURE OF MALE URETHRA AND CORPUS SPONGIOSUM DURING COITUS.

BY F. S. WATSON, M.D.

Cases of rupture of the urethra during coitus are of such comparatively rare occurrence, that I have thought it worth while to report the following case, which came under my notice last summer, at the Genito-Urinary Clinic of the Boston Dispensary.

R. D. presented himself at the clinic with the following story.

Six days previous to visit, while drunk, had connection with his wife, coitus occurring on postillon, the man suddenly felt a severe pain in the penis, hemorrhage from the urethra followed and persisted as a slight oozing for two days.

A swelling surrounding the urethra, and extending from about one inch behind the meatus, to the perineum appeared immediately after coition. Two days after the accident micturition became difficult, owing to a diminution in the size of the stream, and at the end of the next two days there was complete retention of urine. He then sought relief.

The bladder was distended, reaching two-thirds of the way to the umbilicus. A swelling as already de-

scribed occupied the tissues surrounding the urethra, and greatly increased the size of the penis; there was no discoloration; the swelling was hard and tense. A No. 12, English catheter was passed into the urethra, and met with an obstruction two inches behind the meatus; slight pressure easily overcame this obstacle, in passing which the impression to the fingers was as though the instrument had slipped over a ridge of ruptured mucous membrane. Immediately after the eye of the catheter had passed this point, the urine began to flow through the instrument. About forty ounces of clear urine were allowed to drain slowly away through the catheter, and the patient thus relieved was sent to the Carney Hospital. In the evening the patient being unable to urinate voluntarily, the house officer drew off thirty-one ounces more of urine.

The obstruction to the outflow of urine being complete, a soft rubber catheter was tied into the bladder and retained there; on the following day pus discharged itself freely from the meatus. The urethra was now irrigated several times daily with the following solution: Potass Permang. .04; Aqua 200. The patient continued to wear the catheter, which was frequently changed, for twenty-six days, during which time the discharge of pus slowly diminished, and the swelling decreased in size. He then removed the catheter himself, and tried to urinate. Only a little urine came, the stream suddenly stopped, the swelling became at once very large and tense again; during the night he had several chills, and high fever.

On the following day, I freely incised the swelling from without, in the mediary line on the raphe. About an ounce of fetid pus was evacuated from an abscess cavity lying on either side the corpus spongiosum, and beneath the corpora cavernosa. A ragged transverse rent was seen to occupy the floor of the urethra, about two inches behind the meatus. The abscess cavity and the urethra were thoroughly washed out with a solution of corrosive sublimate, 1-10,000. Iodoform was blown into the wound, a drainage tube inserted, and the wound dressed. Directions were given to catheterize the patient at each call to micturate, and that the urethra be washed out after each catheterization with corros. sub. sol. 1-10,000. Two days later the drainage tube was removed, and the wound had entirely closed two weeks later, except a minute fistula, which persisted for a month.

The temperature fell to normal on the day of the operation, and did not rise again. At the seat of the rupture of the urethra, a traumatic stricture resulted, which was very dense, and showed a tendency to very rapid contraction.

The patient was last seen two months after being discharged, when he was advised to have internal urethrotomy performed, which he refused, and was lost sight of. This case besides being interesting from its rarity presents a few other points worthy of attention.

*First.* The accident caused rupture of the urethra and corpus spongiosum only. As shown by the hemorrhage occurring from the urethra, and no discoloration of the penis taking place.

*Second.* The obstruction to the flow of urine and consequent retention, was probably caused by a valve-like action of the ruptured mucous membrane, and not by pressure from the surrounding infiltrated tissues. This was illustrated by the ease with which the catheter No. 12, Eng., passed the obstructing point.

*Third.* The pressure caused by the urine accumu-

lated in the bladder was sufficient to hold open both sphincter vesicae, and compressor urethrae, shown by the fact that as soon as the eye of the catheter passed the seat of injury the urine began to flow through it, and continued to do so until the bladder was somewhat relieved of its contents, when it had to be carried on into the viscous to obtain the rest.

*Fourth.* Suppuration occurred in the tissues about the urethra, from the entrance into them of urine through the rent in the urethra, and its subsequent decomposition. This took place in spite of the retention of a catheter in the bladder.

*Fifth.* As soon as the healing process had gone on far enough in the urethra to make drainage from the abscess insufficient by that road, retention of pus with fever at once announced itself.

*Sixth.* The case serves as an illustration of the well known rapidity of formation of traumatic stricture, and its great contractility. And the inefficiency of dilatation as a means of keeping such a stricture open, especially in the anterior urethra. (In spite of the passage of a steel instrument every few days, the calibre of the urethra had contracted to twenty-one *peræ* at the end of two months.)

The treatment to be adopted in such a case is, I think, emptying of the bladder *very slowly*, using several catheterizations and occupying a number of hours before all the urine be drawn off. An overdistended bladder should never be suddenly emptied!

Subsequent catheterization at each call to micturate, each operation to be followed by irrigation, of the urethra, by an antiseptic solution, introduced through a retrojecting soft rubber irrigator.

If suppuration occurs, and abscess formation takes place around the urethra, external incision, drainage and cleansing of the wound.

The passage of a full-sized steel sound or bougie, every few days, until such a time as the stricture formation calls for operation, and then the employment of internal urethrotomy, dividing the obstruction to the size of the urethra one has to deal with.

## RECENT PROGRESS IN PATHOLOGY AND PATHOLOGICAL ANATOMY.

BY WILLIAM F. WHITNEY, M.D.

### THE CONTEST BETWEEN THE CELLS AND BACTERIA.

At the present time, when the rôle played by the micro-organisms is attracting so much attention, Virchow<sup>1</sup> has well chosen the above subject for the opening paper of the one hundred and first volume of his *Archiv*. With the beginning of that journal, he departed from the old epigenetic explanation of many pathological phenomena and established in its place the theory of descentence. This he formulated in the sentence of *omnis cellula e cellula*. The plastic material and evulution was replaced by the idea of the inherited continuance of the cell. From this time, the unicellular plants and animals began to assume a prominent place in scientific botany and zoology. As years have gone by, the conception of these organisms has been greatly modified; but each year has more clearly proved that the vital peculiarities and powers of a single cell of a complex organism must be placed in the closest parallel with these lowest forms of life.

From this has resulted a sort of personification of the cell.

As new and different aspects of vital activity were demonstrated, there were those who thought the cellular theory was to be set aside. Even as instructive and convincing a fact as the independent movement of the white blood corpuscles has been regarded as making a breach in it, while in reality it only substantiated and expanded it.

It was otherwise in respect to the external influences to which the cells were subjected. Etiology, it cannot be denied, was a long way behind phenomenology, and this became more clearly recognized when parasitic micro-organisms began more and more frequently to be associated with pathological processes. From this, many are willing to conclude that the older knowledge is worthless. But before going too far in this direction, it would be well to see if the relations of these same micro-organisms to disease are as clearly and precisely known as they should be.

The tendency to assume a parasitic origin for all infectious diseases dates from the discovery of the bacillus of anthrax by Davaine in 1854, the micrococcus of variola and vaccinia by Keber in 1868, and the spirillum of relapsing fever by Obermeier in 1873. These are to be regarded as the first proofs of specific diseases due to bacteria. From that, much has been done; but still more remains. For the whole series of the commonest infections and contagious diseases, the proof is wanting of the specific organism, which is presupposed to exist in them. And this is but the first step in the difficult path of a true knowledge of the entire disease.

For with the simple proof of the existence of a bacterium or micrococcus but little has been gained. Neither pathology nor therapeutics can be satisfied with this. In what way is recurrent fever better understood or treated now that a spirillum has been discovered in it? What influence has the presence of a micrococcus in the lymph and tissues on the knowledge of small-pox and vaccination?

If the results claimed by M. Pasteur in the production of an attenuated virus had not drawn attention to them, all the practical interest would have been concentrated in Listerism. And this, it must be remembered, was due more to a divination of genius than a strict scientific prescience.

Nevertheless, the micro-organisms have occupied the foreground of medical attention, and the cells appear almost forgotten. Any one who, by means of his Zeiss-Abbe microscope, has made them invisible and sees nothing but the colored bacteria, might well be justified in believing that they were to be disregarded. But they are there, and they are — let it be openly said — still the chief point of interest. But they are patient and can wait. Their time will come again as soon as the physician has filled some of the gaps in botanical knowledge. Then will they again take the first place in scientific and practical interest.

Perhaps this may seem to some a little too strongly expressed. But with the discovery of each new parasite, the same road is gone over again. First, its detection; then the investigation of its habits of life; then finally, the question, how does it produce the disease with which it is associated? In this third stage, it comes back to pathology and to the very same pathology that was already there. Nowhere is this more apparent than in the history of phthisis. When Dr.

<sup>1</sup> Virchow's *Archiv*, Vol. 101, page 1.

Koch had found the tubercle bacillus, there were some who imagined that all the patient work of the past was superfluous. Unity of the bacillus, unity of phthisis! Tuberculosis of the lungs is identical with cheesy degeneration, tuberculosis of the glands with scrofula, etc. But this beautiful unity has not long held together. Tuberculosis has remained, as it was, an ambiguous process, which commences in many ways; sometimes starting in the mucous membrane of the air passages, sometimes in the interior of the alveoli, sometimes in the parenchyma of the lungs. And further, its products differ greatly; some are simply inflammatory, while others are specifically tuberculous, and whoever will rightly understand its true nature, must learn something more than how to color bacilli. Indeed, the bacillus has done so little to elucidate the problem, that attention has been turned back again to the investigation of predisposition and immunity.

In leprosy this is still more evident. The discovery of the bacillus lepre has shut out an entire series of other possible explanations. But a positive extension in the direction of diagnosis, prognosis and treatment, has not been made. And it will not, until the territory of the previous knowledge of the local affection has been more enlarged than by the addition of a few bacilli to the cells.

Their relation, the explanation of which form the proper nucleus of special pathological, or more widely expressed, medical investigation, can be designated as the struggle between the cell and the parasitic micro-organisms (bacteria, for short.) At this time, two living micro-organisms are in the field against each other. The microscopic cells, the vital elements of the body, on one side, and the yet smaller fungi, the lowest plants, on the other. Each is supplied with its own life, its own activity, its own powers. Which of the two is the attacking party? How is the attack conducted? How is the defence made? Which of the two is destroyed? These are the questions that are to be answered.

Provisionally, more is known of the peculiarities and action of the cell than of the vegetable parasite; but by far, not enough. Haply, however, the activity of the living cell is more easily studied than that of its guest, and scientific interest will thus be naturally turned in this direction.

Furthermore, a distinction is to be made between the action of the bacteria as such upon the cells and their products, especially the poisonous substances formed by them. The isolation of the ptomaines, (or alkaloids of putrefaction), shows the importance of this, and what was originally a purely botanical question, is becoming more and more a chemical one.

On the other hand, it will be the work of the future to investigate the living cell in respect to its powers of resistance and the mechanism of its offensive and defensive weapons.

A step in this direction has been taken by Metschnikoff,<sup>2</sup> who describes the way that bacteria are taken into cells, and who has followed their subsequent history, especially their digestion in the cells. Though the ability of the invaders to penetrate the cells has not been clearly proved, still the method which he has employed is a decided advance. He has chosen for his object of study one of the lowest forms of marine life, which from their great transparency and the fluid

medium in which they lived, could be easily observed under normal conditions.

So the question comes back logically to the cellular pathology. And there is no need of a rearrangement of knowledge for the new facts to assume their proper place in the territory of experience already acquired. It is only to be hoped that the new array will be a large one. But it must never be forgotten that aetiology is but a preparatory step to pathology, and that the task of the latter will never be accomplished until the entire course of the disease, that is, the process of the disturbance of the vital activity, is laid bare.

#### ON THE NATURE OF THE GIANT CELLS IN TUBERCULOSIS.

Weigert<sup>3</sup> gives a good illustration of the method of investigation insisted on by Virchow in an article with the above title, in which are embodied his own original views.

Although giant cells had been occasionally noticed in connection with tuberculous products, it was the work of Langhans to establish their proper relations. The name was given, not only from their size, but also for the numerous nuclei which they contained. These last usually occupy a definite position in the periphery of the cell, leaving the central portion free. In some cases they form a continuous mantle, in others they are arranged like a girdle or circle, or are massed together in one part. Their shape, in general, is more oval than round. Many observers have interested themselves in their mode of origin, and it seems to have been proved that they are derived chiefly from the fixed connective tissue elements. Their peculiar appearance has still, however, to be explained.

This was more easily done when they were supposed to represent portions of occluded vessels, in which the thrombus had become cheesy. As this view became untenable, a confluence of cells was invoked; but from this there could only result the pseudo-giant cells of the French; and even this was only possible where the pre-existing cells were arranged in districts, as, for example, in glandular canals. The true giant cell not only has the nuclei arranged in a regular manner, but also shows that they have resulted from proliferation. That is, that they are not separated from each other by any appreciable amount of protoplasm.

Whatever may be their mode of origin, one thing is certain. Whereas, it was formerly believed that they were the product of an excess of "formation irritation," now, from what is known of the formation of division of the nucleus and cell, they are rather to be regarded as the result of a defect. For, if the first was the fact, the protoplasm would have been divided also, and as many distinct cells would have resulted. Now the process has stopped short of this, and has only given rise to many nuclei in a single cell.

There may be very widely different causes for this, but in the author's opinion, the tubercle bacillus is a very important one, and best explains the failure of division of the protoplasm as well as the peripheral position of the nuclei.

The presence of the bacilli within these cells has been accorded by all, but Weigert goes a step further and holds that they also have a particular position, which is on the line separating the free central part of the cell from the outer portion containing the nuclei. The meaning of this is best understood when the rela-

<sup>2</sup> Virchow's Archiv., Vol. 96, page 177, and Vol. 97, page 502.

<sup>3</sup> Deutsch. Medizin. Wochenschr., August 27, 1885.

tion of the bacilli to a large cheesy centre is considered. All agree with Koch that such a centre is, as a rule, poor in parasites. On the other hand, they are found in tuberculous products, which are well supplied with nucleated cells. But it is fair to assume that they must also have occupied at some time the cheesy places from which they have disappeared (on the formation of spores) after having accomplished their work. While on the periphery of such places their growth still takes place. The bacteria have been destroyed in the centre because their supply of nutritive material has been used up. And the fact that they grow well in cavities does not disprove this, as with a free supply of air, new histological and chemical factors have come in.

If, now, the giant cells are looked at in the light of what has been seen in the cheesy foci they are found to present identical conditions, only on a minute scale. This likeness is strikingly shown in the nodules occurring in the livers of tuberculous fowls. Here there are giant cells which assume an irregular cylindrical form with the nuclei all confined to one end. The other end is gradually lost in the cheesy central mass of the entire tubercle. From this the conclusion is justified that a partial necrosis of a single cell can also occur. And in accordance with the present views of the relation of the nucleus to the life of the cell, it is hard to conceive how such large non-nucleated areas could be capable of life.

It may seem as if it were going beyond bounds to speak of the partial destruction of so small a body as a single cell. But this arises from the habit of regarding the cell not only as a unit but as an anatomical one. This, however, is not so, for a consideration of normal changes teaches that a part of a cell may cease to live and be cast off, while the rest persists. The "goblet cells" of the muciparous glands are a striking example of this. While pathologically it is seen in the coagulation necrosis of renal epithelium, in which only the interior of the cell is changed while the external part containing the nucleus remains intact.

But an *a priori* doubt might be raised as to the ability of the bacilli to bring about this incomplete death. It has been usually supposed that after they have once entered a cell they kill it entirely, either by using up its material for their own nutrition, or by the action of their poisonous productions. Such would be likely to take place with a rapidly-growing parasite, but where one is of such slow growth and uses as little food as the tubercle bacillus it is probable that it would kill only that part of the cell which lies in immediate contact with it; while the rest still remains capable of life.

The facts in the history of the tuberculous process seem also to bear this out. For it has been shown that in cases of inoculated tuberculosis the giant cells were not formed at the point of impregnation when many of the rapidly growing ones were introduced. But this only took place when those of slow growth as from the tuberculosis of cattle had been employed, or in situations where only a few could be introduced, as in the lymph canals of the cornea. The fact furthermore, that giant cells are especially to be found in slowly progressive forms of the disease in man stands in accordance with this, as well as that in these forms a proper cessation from the death of the entire cell may be wanting, as occurs in leprosy. On the other hand, acute processes (meningitis, cheesy pneumonia, and tuberculosis of children, monkeys and rabbits) can

run their course without the formation of giant cells, but are prone to diffused caseation from the death of entire cells.

This assumption best explains also the peculiar grouping of the nuclei and bacilli. In this regard, however, an assertion of Koch's must be recalled, namely, that the giant cells are quite persistent structures, while the bacilli are short lived, and can only hold their own by a succession of generations. Bearing this in mind, the cells may be regarded as representing three stages:—

*First stage.* The parasites have killed only a circumscribed part, and the production of nuclei still goes on. These surround the necrosed portion which is not easily to be differentiated. This stage is best seen in the tuberculosis of fowls.

*Second stage.* From the continued action of the microorganism a larger and larger area is destroyed, until the nuclear zone is clearly marked off from the central portion. The bacilli are still scattered everywhere in the cell.

*Third stage.* Here the nutritive material in the necrosed spot has been used up, as is shown by the gradual disappearance of the bacteria from the centre, while they still abound in the periphery. This stage is the one generally found in man.

As long as a new formation of living material on the outside can keep pace with the destruction going on within, the cell can continue to increase in size. But when the latter gains the ascendancy and the last remnant of living tissue is used up, then the cell sinks into a diffuse caseation. At first its shape can still be recognized, but finally it is melted into an ill-defined mass and blends with the general granular detritus.

Occasionally there are found giant cells in which remnants of bacilli can still be made out in the centre, while the peripheral zone is free from them. Such can be regarded as persistent forms in which these cells have conquered the parasitic microorganisms.

#### ON TUBERCULOSIS OF THE MAMMARY GLAND.

Within the last few years it has been shown by microscopic examination that certain cases, which from a clinical standpoint had been regarded as cancer of the breast were in reality tuberculosis. The number of those recorded up to the present time is not large; but now that attention has been directed to the subject an increase will naturally be expected. Orthman<sup>4</sup> adds two to the number already published.

The first was in a woman forty-two years of age. At first, a nodule of the nature of a feruncle was noticed in the left breast. Upon opening this a little pus escaped. In spite of this the tumor increased in size and a fistulous track was established. Later the axillary glands became swollen and they were excised together with mammary glands six months after the disease was first noticed. Preparation made from the immediate neighborhood of the sinus failed to reveal the presence of bacilli, although the structure was regarded as characteristic of tuberculosis. In the axillary glands, however, the presence of the parasite could be readily demonstrated. Disease of no other organ could be detected at the time when the patient left the hospital.

The second was in a woman forty-four years old, who died with symptoms of dyspnea and dropsy. The autopsy revealed general tuberculosis of the internal

<sup>4</sup> Virchow's Archiv. Vol. 100, p. 365.

viscera, and in one breast a tumor which was said to have existed about fifteen months. The gland itself was atrophied, and was traversed by numerous opaque lines, following the course of the ducts. These were of firm consistency, due to thickening of the walls. The interior was filled with inspissated or cheesy material, recalling the condition found in tuberculous of the epididymis. Numerous bacilli were found lying in the cells.

The first case is to be regarded as one of primary tuberculous, while in the last one it is doubtful where the original seat of infection was.

The author thinks the giant cells which were found in the tissues originated in part from the epithelioid cells and in part from the union and subsequent fusion of the epithelium lining the glandular alveoli and ducts.

#### A CONTRIBUTION TO THE ANATOMY OF THE PAROVARIAL CYSTS.

Killian<sup>5</sup> gives the results of a study of a series of five cases. As a rule, the peritoneal covering was found to be smooth, although in two cases the remains of adhesions were evident. These are certainly rare and their existence has been denied by some. In all the cases the infolding of the internal surface was very distinct. This has been explained as due to a contraction of the involuntary muscular fibres of the wall. But these were so sparingly present that they could exert but little influence, while the microscopic examination showed the internal layer of the connective to be thrown into ridges. The Fallopian tube lay in close proximity to the cyst and was apparently increased in length. The fimbriated extremity was somewhat elongated as well as the ovary.

The end of the ovary turned towards the uterus was always found at some distance from the cyst wall. And this is not accidental, as might at first sight appear, for it must be remembered that the parovarium is normally situated near that end of the ovary which is farthest removed from the uterus.

In regard to the cells lining the interior, it is to be remarked that the ciliated ones, which theory demands, were not found. Well-marked cylindrical forms, however, were seen in these cases, but these were always associated with the lower and more cubical ones. The latter were the most constant, being present in all cases. In two cysts there was a single layer of flat epithelium. All stages from high to low forms of cell were found in the same specimen. These are supposed to arise from a thinning of the cyst wall, by which means the cells covering it are pulled out.

In one case a sort of papillary form was found like that occurring in a true ovarian cyst; and in another an unquestionable formation of gland tissue. It has usually been supposed that the accessory cysts which are occasionally found, were derived from other canals, as the normal parovarium has from ten to fifteen in all. But the author is inclined to regard them as retention cysts, from the glandular form mentioned above.

If one wishes to decide whether a cyst is of parovarian origin or not, there must be taken into account, first, whether its position in regard to the neighboring organs is analogous, and second, whether its anatomical structure is referable to it. In regard to the latter point, the author was unable to find any structure that was absolutely characteristic of it, unless it is ciliated epithelium, which must occur very infrequently.

He is therefore forced back upon its position, as before stated, in relation to the tube and ovary, as the chief point in diagnosis.

## Hospital Practice and Clinical Memoranda.

### CASE OF GLANDERS. BOSTON CITY HOSPITAL.

OCCURRING IN THE SERVICE OF E. H. BRADFORD, M.D.  
REPORTED BY ROBERT W. LOVETT, M.D., *House Surgeon.*

W. C., twenty-three years old, an Irishman by birth, had been employed for some months as hostler in the stables of one of the city horse-railroads. He was an intemperate fellow, and so often involved in rows and disputes that he was discharged from the company's employ August 4, 1885. During the last few weeks of his work in the stables he had been given the care of a horse, sick with what appeared to be influenza. Patient was in the habit of picking the scabs from this horse's nose, beside giving him pills and washing away the thick nasal discharge. But the horse grew worse and was sold as suspicious and unprofitable, probably about July 20th, but this date is uncertain. At this time the horse had developed no ulcerations or other positive signs of glanders, but he was regarded with so much suspicion that the patient had been cautioned as to the danger of inoculating himself, especially as he had at that time a sore hand which was generally bandaged.

After his discharge from the stables the patient went upon a considerable spree, secluding himself in his room and drinking heavily, but August 9th, he declared himself sick and took to his bed, complaining of pain in his back and of fever. He had no chills, but some vomiting, and August 11th, he was seen by a physician who pronounced the attack lumbago, and sent him to the City Hospital, where he was admitted.

At the time of admission he presented the appearance of a man in the early stage of typhoid fever. His temperature was 101; he complained of pain in his left side and his back, and his tongue was thickly coated. He had no cough, and the examination of his lungs and heart showed nothing abnormal. There was tenderness over the epigastrium and flanks, and a markedly tender point in the back over the tenth dorsal vertebra. The urine was normal.

He was given rum and quinine in moderate doses, but his fever gradually increased and his general condition became worse. August 15th there were found a few sonorous rales in both chests, and in the left side of the back there was an area of marked dullness extending from the ninth to the twelfth ribs and to the left of the spine for about two inches. This area was tender and slightly bulging.

For about a week there was no marked change, his condition was typhoidal but his mind was clear. His fever was still high, and August 21st a swelling of the dorsum of the right hand, looking like a cellulitis had appeared. There was also a small abscess upon the left calf and acute pain in the left foot was complained of. On August 22d, sixteen days after the first attack, one or two pustules were noticed upon the shoulders looking not unlike large acne pustules, and there were some reddish diffuse swellings upon the dorsum of the left hand. The sweating had begun to be profuse and

<sup>5</sup> Arch. fur Gynaekologie. Vol. 26, p. 160.

the breathing was becoming more rapid. At this time there was no noticeable nasal discharge and there had been no nosebleed. Both heart sounds were weak and variable and there was a systolic murmur at the apex of the heart. The glands of the neck were not swollen, nor was there any glandular enlargement, except in the inguinal glands.

August 23, the eruption was much more noticeable: the pustules were larger, and vesicles and papules were to be seen. There were not more than ten pustules in all this time, and these were situated upon the face and arms. The swelling in the left lumbar region was more prominent and fluctuation was felt. There were several reddish nodules, the size of a cherry, noticed upon the thighs and legs to-day, and reddish blotches with induration upon the feet and hands. He had a slight nosebleed at this time, and sniffed from time to time as if a mild coryza had begun. Examination showed uniform redness of the pharynx. At this time the patient was taking his nourishment very well, being fed every hour, and in addition to this he was given twelve ounces of brandy, and thirty grains of quinine daily. His breathing was rapid and rather shallow and his sweating was profuse. Altogether his appearance was that of a man suffering from severe septic poisoning. He answered questions intelligently although slowly and thickly, and seemed glad to be let alone and lie in a sort of half doze. There had been no diarrhoea and no tympanites.

Between the 23d and 25th of August the development of the eruption was very marked. Upon the 24th, vesicles, pustules, and papules abounded upon the arms and face while tubercles predominated upon the legs. The papules became vesicles and these in turn pustules, very rapidly, and throughout the eruption this seemed to be the course. The tubercles did not break down. Some of the vesicles and pustules were umbilicated, and on the right shoulder a number of pustules had united and broken down, leaving an ulcer with ragged everted edges.

Toward the night of the 25th, low typhoid delirium came on, and respiration became very shallow.

The morning of the 26th the patient was very much weaker and semicomatose. Tracheal rales came on at once and the patient became a little cyanotic. He died at 6 p.m., August 26, twenty days after the onset of the disease and four days after the appearance of the eruption.

From first to last there was no marked glandular enlargement, and no severe coryza, symptoms of septic poisoning seemed to predominate over everything else, accompanied by markedly rapid breathing and profuse sweating. The development of the eruption was surprisingly rapid.

The accompanying chart indicates the course of the temperature, pulse and respiration.

An autopsy was made twenty-two hours after death by Dr. Gannett. Pustules, vesicles, and ulcers abounded upon the surface of the body, the ulcers evidently the result of the breaking down of pustules. The nodules and tubercles upon incision proved to contain pus between the subcutaneous fat tissue and the muscles. One of these nodules had reached the size of a walnut.

An incision made over the swelling in the left lumbar region showed nothing abnormal in the superficial layers, but the deeper layers of muscles from the spine of the left scapula downward were infiltrated with

pus over an area the size of the hand. Between the ninth and tenth ribs an opening from here communicated with a cavity in the perivertebral connective tissue to the left of the vertebral column from the

ninth to the eleventh ribs and along those ribs for a short distance to the left of the vertebral column. In addition there was found cloudy swelling of the heart, liver, and kidneys, and acute hyperplasia of the spleen with a certain amount of chronic endoarteritis.

Some pus was taken during life from a pustule upon the left arm by Dr. Ernst and cover glass preparations made from it showed large and small micrococci and a number of small bacilli. Cultivations made from the pus of a nodule taken from the same arm after death, gave rapid and vigorous growth upon the second day as two distinct colonies: the first was yellow, glistening, and raised above the surface of the culture medium, the second was white. Under the microscope both colonies were seen to be made up of micrococci. About the seventh day a third colony made its appearance, growing very slowly, and of a brownish yellow color. Under the microscope this colony was found to be made up of fine rods about the size of the bacillus of tuberculosis, which answered to the description of the bacillus of glanders, both under the microscope and under cultivation.

— "Luminous doctors' signs are prominently advertised in the pages of a contemporary. That is just the kind of doctors who run the least to such things. As a rule, it is where the "inward and spiritual grace" least abounds that there is the greatest ostentation of the "outward and visible sign."

## Reports of Societies.

### THE AMERICAN ACADEMY OF MEDICINE.<sup>1</sup>

THURSDAY.—MORNING SESSION.

The Academy was called to order at ten o'clock.

A resolution expressing the sympathy of the academy with Dr. H. P. Farnham, in his painful illness, was offered by Dr. H. O. Marcy, and adopted.

The following resolution was adopted:

*Resolved.* That a committee of three be appointed by the president to report at the next annual meeting, and instructed to prepare a statement of the best preliminary education for medical students, and also a statement of the minimum attainment which medical schools should require of students before admitting them to the study of medicine.

It was also resolved to appoint a committee of two whose duty it shall be to report the requirements for a preliminary education of the various medical colleges in the United States and Canada.

The following officers were elected for the ensuing year:—President, Dr. R. Stansbury Sutton, Pittsburg, Penn.; vice-presidents, Drs. Lewis P. Bush, Del., S. J. Jones, Ill., R. L. Sibbet, Pa., and F. H. Gerrish, Me.; secretary and treasurer, Dr. R. J. Dunglison, Philadelphia, Pa.; assistant secretary, Dr. Charles McIntire, Easton, Pa.

Pittsburg was selected as the next place of meeting. The time, the third Tuesday of September, 1886.

The following gentlemen were elected fellows of the academy:

S. M. NELSON, Cambridge, Mass.; J. H. W. CHESTNUT, Philadelphia; RUFUS W. BISHOP, Chicago; E. E. MARIOTT, Springfield, Mass.; GEORGE N. ACKER, Washington, D. C.; H. V. LOGAN, Scranton, Pa.; H. W. ELMER, Bridgeton, N. J.; H. F. HANSELL, Philadelphia; E. W. CUSHING, Boston, Mass.; J. S. WRIGHT, Brooklyn, L. I.; WILLIAM OSGOOD, North Yarmouth, Me.; C. A. PACKARD, Bath, Me.; W. K. OAKE, Auburn, Me.; A. MITCHELL, Brunswick, Me.; D. A. ROBINSON, Bangor, Me.; C. A. KING, Portland, Me.; J. A. STIMULSON, Portland, Me.; G. W. MARSHALL, Milford, Del.; WM. A. HIGIE, Charleston, S. C.; J. B. SHAPLEY, St. Louis, Mo.; M. H. POST, St. Louis, Mo.; C. E. BRIGGS, St. Louis, Mo.; J. S. ALLEYMAN, St. Louis, Mo.; N. S. DAVIS, Jr., Chicago, Ill.; CHARLES EDGAR COOK, Ill. Dr. HENRY H. SMITH, and Dr. S. WEIR MITCHELL, of Philadelphia were elected to honorary membership.

### MEDICAL EVIDENCE.

By THOMAS J. TURNER, Medical Director U. S. N.

The paper had its origin in the writer's duty in connection with the naval retiring board. The positions of the medical member of the board are that of an ordinary witness, that of an expert witness, that of a concurrent judge of both the facts and the law, but with the execution of the verdict the board has no authority whatever.

In the first instance the medical officer makes a physical diagnosis, in the second place he makes a rational diagnosis based upon subjective phenomena. Combining these he arrives at a conclusion. On questions of science, skill, art, and the like, persons instructed on such subject matters, known in ordinary language as experts, are permitted from the necessities of the case, to give "matters of opinion" in evidence; and as to the necessity which permits the introduction of such opinions, each tribunal determines for itself at the time. Herein the expert differs from the ordinary witness who testifies as to "matters of fact."

The boundary line where ordinary testimony ends and expert testimony begins, is not always well defined.

As far as relates to opinions on medical questions, any one at present may be permitted to testify, the question of the special amount of knowledge being left to the jurors to determine. It follows from this that there is no evidence which varies so immensely as so-called expert evidence. It has been decided that a medical opinion may be received as evidence if it is based upon study without practice, or upon practice without study, and it has been ruled that it is not absolutely necessary that one should have studied or practiced medicine.

The opinions of medical men are admitted in courts, upon the condition of the human race; thus, is or was a certain person sick? upon the nature and cause of the disease; the cause of death; the cause and effect of an injury; the effect of medicine or of a particular treatment; the likelihood of recovery; the mental condition of the person; and upon the examination of the party whose condition is under inquiry.

It was the speaker's opinion that the term "expert testimony" was somewhat misleading, and he preferred the term "opinion evidence" as used by Best, as preferable, for opinions may be admitted in evidence by those who could not be classed as experts. The test of the admissibility of opinion evidence seemed to the writer to be this: has the expert witness any peculiar knowledge or experience not common to the world which renders his opinion founded upon such knowledge or experience upon the subject matter under inquiry, of value to the court in determining the truth of the matters at issue? The degree of credence given to opinion evidence should be founded upon the professional skill, the quickness of perception, the powers of discernment, the aptitude, the acquirements and the education, as well as the experience and observation of the expert in the matters upon which his special expert knowledge arises.

### REPORT ON LAWS REGULATING THE PRACTICE OF MEDICINE IN THE UNITED STATES AND CANADA.

By RICHARD J. DUNGLISON, M.D., of Philadelphia, and HENRY O. MARCY, M.D., of Boston, was read by Dr. R. J. Dunglison.

The doctor said that so little change has taken place within the last twelve months with reference to legislative restriction of the practice of medicine, that your committee might in a few brief sentences dismiss the subject with the statement of the actual work accomplished in this direction. The honest efforts of medical men and of others during the past year to accomplish creditable results in the States for the repression of quackery have been unabating, but in several cases, disappointment has been the only issue of their labor. Indiana and North Carolina are the only States in which any alteration in existing laws have been made.

Your committee entered into correspondence with medical gentlemen in the different States with regard to the working of laws for the regulation of the practice of medicine, and their replies are submitted.

The following is a synopsis:—

From New York it was reported that the act of 1884, had not been effective in excluding from the profession grossly incompetent and uneducated men.

Massachusetts has no satisfactory law on this subject.

In Pennsylvania the registration act is executed

<sup>1</sup> Concluded from page 156.

about as well as any law of the kind could be without an executive head. It has stopped the non-graduated class from practicing.

From Michigan, it is reported that the present law is defective.

In Tennessee, there is no law regulating the practice of medicine.

In Ohio, the only law is one passed fifteen years ago, requiring a diploma or a certificate from a chartered medical school. Several bills for regulating the practice of medicine have been proposed, but none have been adopted.

Wisconsin has adopted no law for the regulation of the practice of medicine.

Kentucky requires a diploma or a certificate from a State Examining Board. This law is working well.

Dakota, last winter passed an act establishing a Territorial Board of Health, the function of which is to grant licenses to practice medicine and surgery in the territory. There are however several difficulties in the satisfactory enforcement of this law.

Texas is practically without any law upon this subject.

In North Carolina an act has recently been passed making it a misdemeanor punishable by fine or imprisonment or both, to practice medicine in North Carolina, without a license from a board of examiners elected by the State medical society. The results of this law have so far been satisfactory.

In New Jersey, the registration law has proved of little service.

Nebraska has a registration. While its results are not evident, yet it seems to be preparing the way for more effective action.

Iowa has no law regulating the practice of medicine.

Two years ago, Virginia passed a law establishing a State board of examiners. This is working satisfactorily.

Maine has no law on this subject.

In New Hampshire, the law regulating the practice of medicine has not accomplished very marked results.

In Maryland, the law works very badly.

In closing, Dr. Dunglison said, "From this sketch of medical legislation, the inference is fairly deducible that the legislation upon the subject of medical practice is not yet placed upon a sufficiently firm foundation to gratify the advocates of restrictive enactments, and that the obstacles to such healthful results are still operative but not insurmountable."

Dr. BENJAMIN LEE, of Philadelphia, read a paper on HEALTH OFFICERS, ANCIENT AND MODERN.

The important position assigned to hygiene and State medicine during the past decade is an evidence at once of the advanced stage of civilization and of the dense and rapidly increasing population. It also indicates that long occupancy of the land by successive generations has at length overtaken the regenerative and self-purifying energies of the earth, and that extraordinary methods have now become necessary. Reference was then made to the honors bestowed on the officers of public health in ancient Rome, and the high esteem in which they were held. To this was largely attributed the excellent sanitary condition of that city.

The second portion of the paper was occupied with a consideration of the organization of boards of health.

The first point made was that in selecting the material for boards of health, politics, in the bad American sense of the term, should be rigidly excluded. Where it is possible to avoid it, the members should not be elected by the people; especially is this the case in large cities.

*Secondly.* Boards of health should be composed chiefly of physicians, but at least one member should be a man eminent among his fellows for prudence and judgment in trade and commerce, for doctors are, proverbially, bad business men.

*Thirdly.* As it is desirable that there should be harmony of action and of sentiment between the municipal government and the Board of Health, there should be a representative of the one on the other.

*Fourthly.* It is essential for the practical working of the Board that it should employ a paid agent who shall devote as much time as is necessary to inspection and investigation of the sanitary conditions of the locality, and carry into execution the orders of the Board.

*Finally.* Every member of the Board should receive a fair, and even generous compensation for his labors.

Adjournment of Morning Session.

#### AFTERNOON SESSION.

Dr. SAMUEL N. NELSON read a paper entitled

#### MICRO-ORGANISMS AND THEIR RELATION TO DISEASE.

Dr. Nelson began by saying that the importance of the subject, already much discussed, was the only apology offered for presenting it. That these minute organisms make up what they lack in size, by the interest they are causing in the scientific world. That great numbers of observers are at work on both Continents in the solution of the germ theory of disease. Their history is related to that of spontaneous generation, to that of the fermentations, to the pathology and therapeutics of a great number of virulent and contagious affections, and in a more general manner, to all the unknown field, which, notwithstanding the efforts of modern science, still surrounds the origin of life and its preservation.

The bacteria belong to the vegetable kingdom and are the lowest of organisms, being merely cells of a globular, oblong, or cylindrical form, reproducing themselves partly by spores and by transverse division. The best authorities now adopt the simple classification into (a) bacilli, or the rod forms, and (b) micrococci, or the round forms. The first observer who recognized them was Loewenhoeck, as early as 1675. Their study has advanced with the improvement of the microscope, until now, many forms are only seen by the best of lenses aided by special condensers. The more delicate and exact methods of the most recent observers with regard to their nature, show that there are many varieties of them, each of which has its own conditions of growth and varies in its susceptibility to different temperatures and chemical reagents. Apparent identity of form does not necessarily indicate identity of nature. They may be cultivated in both solid and liquid nutrient media.

The theory of a causal relation between bacteria and diseased processes has recently received a wide acceptance. In some diseases this relation is demonstrated, while in others, it is presumed on the ground that bacteria are found in the blood and diseased products. It is not only necessary that the germs should

be isolated and grown in pure cultures, but by inoculation the disease should be produced in healthy men or animals with a reproduction of the bacteria. Reference was then made to the various diseases that have been studied from this standpoint, and the present status of our knowledge was remarked concerning tuberculosis, cholera, variola, scarlatina, measles, diphtheria, erysipelas, etc. Dr. Nelson related some of his own experience in cultures of the micro-organisms of many of these diseases, with which he has made many thousands of experiments the last five years, both at home and in Germany, under the supervision of Professor Koch in his laboratory in Berlin.

The next paper was on

#### OBSERVATIONS ON THE RELATION OF BACTERIA TO CERTAIN PUERPERAL INFLAMMATIONS.

By DR. ERNEST W. CUSHING, of Boston.

These observations were based on the results of examinations of the bodies of such women as died from these maladies in the General Hospital at Vienna, last spring. He called attention to the great difference between the customs and rules governing the obstetric assistants and students in Berlin and in Vienna. In the former city, every precaution is taken to avoid not only direct infection, but also any possible carrying of germs in the hair or clothing, as if bacteria were freely present in the air. In Vienna, although the possibility of so finding them is admitted in theory, yet in practice, the assistants and students are allowed to be present at autopsies. Obstetric operations and laparotomies are performed before the whole class, without spray, and the chief assistants give operative courses on the cadaver every afternoon, relying for safety on washing, bathing, and change of clothing. Practically, sepsis arising in the hospital is very rare, and the results obtained by avoiding direct infection through the fingers and instruments, were regarded by the speaker as an argument in favor of the view that puerperal fever is not an entity, the poison of which is carried about in the air and enters the system through the lungs, etc.; but that such fevers are the result of the invasion and multiplication of bacteria, arising from the infection of the uterus or abraded vagina, as a rule, directly from hands, instruments, or applications.

Discussing the results obtained by the examinations above mentioned, the reader stated that the most frequent cause of infection was the streptococcus; the next the staphylococcus, with which is frequently associated the bacillus pyogenes fortidus. The first occurs in chains not distinguishable from those of erysipelas, the cocci usually lying in pairs, each pair representing a link. The staphylococci occur in bunches, like those of grapes. One or the other of the above were found in all acute cases examined, and were present in the uterine or iliac veins. In pelvic abscesses, they were found in the lungs and joints, and, in fact, wherever metastatic abscesses occurred. Microscopic preparations of the above were shown and three specimen cases described. Finally, puerperal inflammations were compared to infected wounds. The powers of the system to resist, fence out, and kill the invading bacteria when the latter are not continually reinforced, were emphasized, and an active hopefulness was advised in regard to treatment, which to be successful, should be analogous to that of surgical wounds, that is, prompt removal of decomposing matter, evacuation of pus, cleansing and disinfective douches, and drainage.

DR. R. STANSBURY SUTTON said that while there was no question as to the success achieved by the use of antiseptics in general surgery, yet in abdominal surgery, the best results so far had been obtained by strict attention to cleanliness without the use of any antiseptic agencies. He agreed with Dr. Cushing that when the poison enters the abdominal cavity in laparotomy, or into the vagina or uterus in puerperal cases, the germs are not carried by the atmosphere, but by the hands, the forceps, ligatures, or instruments. As far as abdominal surgery was concerned, he thought that all chemical agents could be discarded, but cleanliness could not be lost sight of. He then referred to the injurious effects which had at times resulted from the absorption of such agents through the peritoneum.

DR. HENRY O. MARCY related a case bearing on the introduction of antiseptics into the peritoneal cavity. It was that of a child four years of age, whose abdomen was filled with pus, in which the streptococcus was found. The pus was evacuated and the peritoneal cavity thoroughly washed out with bichloride of mercury solution. The patient recovered without a bad symptom.

#### MEDICAL LICENSES AND MEDICAL HONORS.

was the title of a paper read by DR. EDWARD JACKSON, of Philadelphia.

A comparison was made between the requirements of the medical colleges of this country when first organized and the requirements of to-day, and the gradual lowering of the standard with the corresponding decrease in the honors conferred was noted. While the population had increased twenty times, the number of graduates had increased five hundred times. Part of this increase is due to the fact that men who formerly practiced without a degree, now attend colleges and receive the degree.

In 1881, the medical diploma was put to a new use and became a license to practice. The inefficiency of the registration law, as well as the lessened honor which attaches to the medical degree, was shown by the fact that in fifteen hundred registrations, only forty-eight were destitute of the doctor's degree, and these belonged to the poorest order of irregular practitioners. The speaker thought it doubtful if any system of State license to pursue any calling should be looked on with favor. If adopted, it must be removed from all possibility of lowering competition, and surrounded by every guarantee of honest enforcement which disinterested examiners and full publicity can give.

A paper entitled "The Physician and his Patient," by Dr. J. D. Kelley, of Erie, and one by Dr. Lewis P. Bush, of Wilmington, Del., on the "Physicians of Delaware in the Eighteenth Century," were read by title.

The President-elect was then introduced and made a brief address.

The Academy then adjourned.

—The *British Medical Journal* in answer to the query of a correspondent, says that "the sinew of the hip upon the hollow of the thigh which the children of Israel eat not of," is the ischiatic plexus of nerves with all its branches and ramifications from the pelvis down to the foot.

# PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL OBSERVATION.

H. L. BURRELL, M.D., SECRETARY.

NOVEMBER 2, 1885. DR. J. H. MCCOLLOM in the chair.

DR. H. DERBY read a paper

## ON THE ABUSES CONNECTED WITH GRATUITOUS MEDICAL TREATMENT.<sup>1</sup>

DR. HENRY I. BOWDITCH said that the paper was an instructive one and showed some evils existed with which he thought it would be hard to deal.

As to the apparent increase of the number of beneficiaries in the Eye and Ear Infirmary during the progress of years, he thought that in order to be sure of such increase some consideration at least should be given to the large increase of population in the city and to the great numbers that were daily brought to the metropolis by the various railroads—during the later years. If this could be done, the *apparent increase* of beneficiaries would probably be lessened.

DR. C. E. STEDMAN remarked that several years ago Dr. O. F. ROGERS contributed several able and pointed letters on the subject so cleverly handled by the reader to the *Boston Medical and Surgical Journal*. They were replied to, or commented on by the *Journal*. The difficulty of effecting any reform in the matter seemed to be owing to the teachers of medicine who felt that they must have all the available material of the dispensaries and out-patient departments; and that the young men who were so rash as to try to get a living by the practice of medicine must look out for themselves.

DR. C. H. WILLIAMS said that in an out-patient service it was not right to expect the physician to give his time to the questioning of patients as to their means in the endeavor to eliminate the unworthy; it was entirely apart from their medical work, and often took more time than the ordinary examination of the patient. The managers of our large institutions, when they ask their medical staff to devote a great deal of time and skill to unpaid work at a hospital ought to take some measure to protect their staff from imposition while carrying on the work.

DR. C. P. PUTNAM said that free patients were wanted by practitioners for instruction. He did not believe that gentlemen served in hospitals as a sense of duty, but as a pleasure, and not the practitioners so much as the managers are the ones who invite the patients.

Regarding operations, he thought that surgeons did not object to caring for private patients in hospital, as it was usually a rare and interesting operation that they were called upon to do, and he thought that surgeons were glad to do the operation for its own sake.

There is a class of people who are not very rich nor very poor, who expect to pay their ordinary bills to the grocer, butcher, etc., but do not feel like paying a doctor's bill; they are a cleanly set, and are more agreeable to treat at an out-patient's than the ordinary habitué.

DR. PUTNAM thought that doctors rather liked these patients and encouraged their coming.

This middle class, the speaker thought, considered it rather the fashion to receive charitable medical treatment.

Many men do not care to take a small fee, considering that in that way they depreciate their services, and these men send their patients to a hospital.

He further alluded to the possibility of patients paying a fee for the treatment of, for instance, an abscess, whereas if they had necrosis, an affection which would require long and careful treatment, they would be unable to meet their debt.

The custom of charging a small fee at clinics he did not like, and suggested that a certain number of patients could be treated at out-patient departments in consultation; that is, that they should bring with them a note from their own doctor.

The speaker favored the plan of medical assurance clubs, and concluded by saying that he thought that a concerted action on the part of all the different hospitals and dispensaries might result in good.

DR. HAVEN did not feel that there was such a marked injustice done to young practitioners, for if a physician charged small fees he soon acquired the name of being a cheap doctor. He had heard men designated as fifty-cent doctors. This he felt was an injury to the practitioner. Dr. Haven favored the contract system, and believed that poor people who required special skill from specialists would gravitate to the clinics where special material was needed.

DR. E. L. PARKES had listened to the paper just read, with much interest. He had acted as recording officer at the Infirmary, and felt that a just discrimination should be used in directing suitable cases to the junior specialists. He had learned to regard with suspicion the class of patients that came from a distance, experience having taught him that they were frequently able to pay for advice. He called attention to the fact that a clinic varies from time to time, according to what surgeon is on duty, and believed that many patients obtained an opinion in this manner from an especially popular and skillful practitioner.

DR. C. M. GREEN had always endeavored to discriminate in his treatment of charity patients, and had found that one could not depend upon personal appearance as a guide, as to whether the person was deserving or not. He had felt the injustice of the gratuitous treatment of prostitutes. He had always thought that the sending of patients to one's own office from a charity, laid one open to the charge of having a selfish motive in so doing. Dr. Green asked whether the members of the society considered that clergymen were to be considered subjects of gratuitous treatment.

DR. H. I. BOWDITCH said that he always made a discount from his regular fee when it seemed necessary, and explained to clergymen that it was owing to their profession that the deduction was made.

DR. H. DERBY discriminated in reference to clergymen and charged them what he felt that they could afford to pay.

DR. W. A. DENN then read a paper upon

## A CASE OF HYDATIDIFORM MOLE WITH PLACENTA PREVIA.

DR. H. I. BOWDITCH complimented the reader, and thought that it was most fortunate that the case had fallen into such good hands.

DR. C. M. GREEN had never met with a similar case, and spoke of the rarity of the combination of the two conditions of mole and placenta previa.

<sup>1</sup> See page 460.

## Recent Literature.

*Transactions of the American Gynecological Society.*  
Vol. IX, for the year 1884. New York: D. Appleton & Co. 1885.

The address of the President, Dr. Albert H. Smith, is an interesting and comprehensive review of the chief prevailing theories of the aetiology of what is known as puerperal fever. The writers of recognized authority are broadly divided into the essentialists and the infectionists: the former holding mainly the doctrine advanced by Dr. Barker in his *Puerperal Diseases*, "that there is a distinct fever altogether apart from any local lesion, or specific poison other than its own"; in other words, that puerperal fever is an essential disease: the latter school, the infectionists, regarding the disease as a traumatic infectious fever, in short, as septiciæmia. This latter school is further divided, however, into the followers of Semmelweis and those of Pasteur, the former believing that the malady results from the absorption by traumatic surfaces of decomposing animal matter, which may be of either autogenetic or heterogenetic origin; the latter, that the disease is due solely to the entrance of micro-organisms into the circulation, either through the open surfaces of the parturient canal or through the sound mucous surfaces of the lungs or intestines.

While not prepared to say that the views of the pangermists, as the Pasteureans are sometimes called, are not true, Dr. Smith regards them as not proved, and does not hesitate to ally himself with those who believe in the septic origin of the disease. He would, therefore, rely on a careful prophylaxis, and the intelligent and faithful use of antiseptic measures.

Dr. Paul F. Mundé contributes a valuable paper on "Interstitial Cervical Fibroids as a Cause of Dystocia, and their Removal by Vaginal Enucleation." From his personal experience with one case, in which he successfully enucleated at the sixth month a tumor weighing three pounds, the mother recovering, but subsequently miscarrying, and from his comparison of eight other similarly treated cases with the results obtained by Cesarean section, the author is strongly impressed with the superiority of enucleation by vagina. In the discussion of the paper, the opinion prevailed that it is better to wait until labor begins before attempting enucleation, as the danger to the mother is no greater at that time, and perhaps even less; while the chances of delivering a living child are much greater.

Dr. T. Gaillard Thomas read a report of six additional cases of extra-uterine pregnancy, supplementary to the twenty-one cases reported two years ago. The paper and the subsequent discussion are of great value in clearly defining the method of treatment which promises the best results. Dr. Thomas still believes in the use of electricity to kill the foetus in the early months rather than resort to laparotomy. If the pregnancy has advanced beyond four and a half or five months and the child is living, he would wait until the end of the ninth month and then remove it living by laparotomy. If the child is dead, he would wait for the shrivelling of the placenta, unless unfavorable symptoms demand earlier interference. In connection with Dr. Thomas' paper, Dr. R. B. Maury's case of tubal pregnancy, with rupture of the sac in the second month is of interest, in regard to the propriety

of early laparotomy, that is, at the time of rupture. Dr. Maury's opinion is that at the time of rupture effort should be directed solely to the relief of shock, from which, rather than from collapse from hemorrhage, the patient is in greatest danger. Subsequent operation would depend upon the age of the fetus, the amount of extravasated material, and the character of the resulting inflammation.

The paper by Dr. Mundé on the "Limitation of Vaginal Hysterectomy for Cancer of the Uterus," and the subsequent discussion, in which many members took part, constitute a very valuable contribution to the literature of this subject. The essay is intended to controvert the opinion advanced by Dr. A. Reeves Jackson in his paper read at the preceding meeting of the Society, namely, that extirpation of the cancerous uterus is not a justifiable operation. The question as viewed by this Society, is now fairly before the profession. For our own part, we believe that in properly selected cases, that is, in those in which the disease cannot be entirely removed by excision of the cervix, but in which the growth has not extended to the parametrium, vaginal extirpation is a justifiable operation *to try*. What the ultimate decision will be concerning the value of the operation we cannot tell: it is still in its infancy; but, in view of the inevitably fatal result of this disease when not arrested, we believe it not only justifiable for, but incumbent on, the profession to give the operation of vaginal hysterectomy a long and patient trial.

The space at our command does not allow us to notice the other papers in this admirable volume. The title-page is faced by a portrait of the late Dr. James D. Trask, and the volume ends with a worthy memoir of J. Marion Sims, by Dr. Ely Van de Warker. The portrait of Sims which accompanies the memoir is excellent. C. M. G.

*The Use of the Microscope in Clinical and Pathological Examinations.* By DR. CARL FRIEDLAENDER. Translated with the author's permission by HENRY C. COE, M.D., etc. New York: D. Appleton & Co. 1885. 195 pp.

We are glad to see that a good translation of this valuable little book has been made. The author is well known for his original work, and we can feel assured that what he writes must have come from practical experience in the laboratory, and is not simply a product of the "library table."

The first half of the book is devoted to the preparation and staining of specimens for microscopic examination. Of late years, the latter part has been so greatly developed that it has almost become a study by itself, and the beginner is often perplexed in knowing what to choose. Here the selections have been well made, and the particular end aimed at by the method clearly shown.

In the second half, the examination of fluids and such other substances as are readily examined without special preparation, and the aid which such examination can give to clinical medicine, is dwelt upon. We wish that the differential diagnosis between the different ovarian fluids and ascites might have been taken up, but the subject is such a large one that it would have extended the work too far. It is not intended as a treatise on pathological histology, but rather as a practical guide, and as such we can most heartily recommend it.

# Medical and Surgical Journal.

THURSDAY, NOVEMBER 12, 1885.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly, by CUTPLES, UPHAM & CO., Boston. Price, 15 cents a number; \$5.00 a year, including postage, to subscribers in the United States and Canada. Foreign subscribers are charged the postage in addition.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.*

CUTPLES, UPHAM & COMPANY,

235 WASHINGTON STREET, BOSTON, MASS.

## RACIAL CHARACTERISTICS OF THE JEWS.

THE question whether the race of modern Jews is or is not a pure one, which has received considerable discussion in its historical aspect, is taken up on its anthropological and anthropometrical side by Mr. Joseph Jacobs in the *Journal of the Anthropological Institute of Great Britain* for August. The arguments therein advanced are reviewed in an interesting article in *Science*, October 9, 1885.

From his former studies, Mr. Jacobs takes the following statements: 1. Jews have a less marriage rate, less birth-rate (both due largely to the less mortality of Jewish children), and less death-rate than their neighbors. 2. They marry earlier. Cousins intermarry more frequently, perhaps three times as often. 3. Jews have larger families, though fewer plural births. Mixed marriages with foreign races are comparatively infertile. 4. Among Jews, male births are more frequent, still births and illegitimate births less frequent than in the average population. (Amongst the illegitimate births the proportion of still-births is not less.) 5. Jews have a smaller mortality of children under five. (Not true of Jewish illegitimate children.) Deaths over sixty are more frequent; suicides are less frequent than normally. 6. Their claim to immunity from certain diseases (phthisis, cholera) is doubtful. They are apparently more liable to diabetes and hemorrhoids, and have, proportionally, more insane, deaf mutes, blind and color-blind. 7. A vast majority live in cities. They have a larger ratio of poor.

Of these conditions only four are held to be of racial as distinct from social origin, and of these some, as the smaller number of twins and triplets, are at present quite inexplicable. The relatively greater infertility of mixed marriages is based on the following facts:—

In Prussia, between 1875 and 1881, 1,676 such mixed marriages resulted in 2,765 children, an average of 1.65 per marriage; while the average for pure Jewish marriages was 1.41, — *nearly three times as great*. In Bavaria (1876–80), 67 such marriages showed an average of 1.1 against 1.7 for pure Jewish marriages.

Other apparently racial peculiarities, namely, greater

longevity and liability to certain diseases are not as yet established on indisputable grounds. For instance, insanitary modes of life, as in crowded tenements, weaker constitutions and greater proportion of men unfit for military service are against the fact of longevity. Moreover, other factors favoring longevity, such as more healthy occupations, greater care of their women, and tranquilizing effect of their religion and family life, belong rather to social than racial considerations.

Jews, we are told, are shortest and narrowest of Europeans (Moyars perhaps are shorter). Their height is 5 ft. 4 in.; girth 31.6 inches. The importance of social influences is seen in the measurement of 130 English Jews of the better class, whose average height was 5 ft. 7 in., and girth 35.2 inches. As to shape of head, they are brachycephalic, or short headed, the cephalic index being 83.4. They have fewer blue and gray-eyed individuals, and more brown and dark-eyed than their Teutonic neighbors. So also their hair and skin are darker. The statistics on color-blindness are unanimous, making three Jewish children so afflicted where only two would be found in other races. The common notion as to length of nose is supported by measurements, while that of the thickness of the lips is not.

A number of photographs of Jewish boys' faces taken at random from the Hebrew Free School of London are given and also composites prepared by Mr. Francis Galton according to his well-known process. These, by the way, Mr. Galton considers the best composites he has ever prepared. In point of beauty the composite portrait reproduced in *Science* is certainly of a high order, although the children from whom it was formed were all of poor families and the individual pictures are none of them specially fine-looking. Mr. Jacobs thinks that we have in this composite the nearest representation of the lad Samuel, or the youthful David. He also identifies the features of the captive Jews of Lachish in the Assyrian *bas relief* (B. c. 701) with the modern features, thus showing the persistency of the Jewish type. "If these Jewish lads," he says, "selected almost at random and with parents from opposite parts of Europe, yield so markedly individual a type, it can only be because there actually exists a definite and well-defined type of modern Jews."

Historically, Mr. Jacobs holds that the evidence also favors the purity of the race. The effect of proselytism has been exaggerated through neglect of the fact that only one small class, namely, the "Proselytes of Righteousness," so called, had the *jus connubii*. Then the strong penalties attaching to marriage in the early days, and other segregative influences, among them the existence of the *Cabanim*, (about five per cent. of all the Jews), who were forbidden to marry outside the race at all, combined to reduce the foreign element. Furthermore, it is pointed out that in all species, the male varies more than the female; indeed, variation in the latter produces a new species. But the variations of Jewesses are less than those of Jews. Finally, the less fertility of mixed marriages compared with

purely Jewish ones would cause a foreign element, even if introduced to grow less conspicuous. An intermixture of foreign blood amounting to one-tenth per cent. would, from the lessened fertility of mixed marriages, become, he estimates in two hundred years, only one-fiftieth. The popular belief as to the essential purity of the Jewish race would thus seem to have scientific corroboration.

#### THE VITAL STATISTICS OF MASSACHUSETTS FOR THE YEAR 1884.

DURING the year 1884, there were reported in the State of Massachusetts 48,615 living births, 17,333 marriages, and 36,990 deaths, which, with an estimated population of 2,037,390, makes the birth-rate 23.86, death-rate 18.15.<sup>1</sup>

The birth-rate is the lowest, with three exceptions since 1850, and 3.17 lower than the average of the thirty years ending in the year of the last census, 1880. It varied, as usual, according to the population, in the various cities and towns, the extreme this year being in round numbers, 30 in the large cities and 15 in the towns of less than 1,000 inhabitants. The ratio of males to females born alive was 105.4, quite near the average. There were 1,628 still-births, and 891 recorded as illegitimate. Native mothers bore 23,347 children during the year, foreign-born mothers 23,808, excluding 1,460 births of unreported parentage, the last census making 50.61 per cent. of the population of the State of purely native-born parentage. The distinction of native and foreign, however, is fast losing its significance, and 8,671 births in 1884 were of mixed parentage.

The marriage-rate is lower than in any other previous year except during the years 1875 to 1879. The average age of first marriages in men was 26.6 years, in women 24.1. There were 733 fewer marriages than in 1883, the financial depression showing itself, as always before, by a lessened ability in the community to marry.

There were 614 divorces granted, 410 to women, 204 to men; 278 for desertion, 163 for adultery, 79 for intoxication, 58 for cruel and abusive treatment, 22 for extreme cruelty, 9 for neglect to provide, 1 for imprisonment, 1 for impotency. The number of divorces annually, from 1865, has been 333, 392, 282, 339, 339, 379, 325, 312, 419, 617, 577, 525, 553, 600, 546, 580, 409, 515, 655, 611. The population in that time has increased from 1,267,031 (census) to 2,037,390 estimated.

If we assume that the population is correctly estimated (on the basis of 511,997 polls) the death-rate (18.15) is .80 below the average of the four years since 1880, 1.06 below the average from 1876 to 1880, 1.11 less than the mean from 1851 to 1880 and exceeded in every year except 1852, 1856, 1859, 1866, and 1867 since 1850. Of the total number of deaths, 20.91 per cent. were of children under one year of age,

32.33 per cent. under five. The "zymotic" diseases caused 21.1 per cent. of all the deaths, as compared with an average of 24.5 for the past ten years, the mortality from the most prominent nine being as shown in the following table:—

	Dysentery.	Typhoid Fever.	Whooping Cough.	Group.	Diphtheria.	Measles.	Scarlatina.	Cholera Infantum.	Small Pox.	Total.
1875	437	1,059	242	680	1,200	233	1,684	2,696	34	8,175
1876	417	881	192	684	2,610	47	1,292	2,087	31	8,171
1877	580	814	269	544	2,634	135	467	1,927	26	7,496
1878	662	679	490	583	1,354	307	401	1,573	2	6,482
1879	372	637	302	559	1,734	19	850	1,349	8	5,302
1880	355	882	230	625	1,709	236	574	2,118	38	6,867
1881	360	1,052	217	677	1,706	290	397	1,861	47	6,565
1882	338	1,079	265	494	1,250	68	518	2,150	45	6,163
1883	336	860	137	539	1,091	321	575	1,941	5	5,796
1884	254	875	410	562	1,083	75	627	2,081	3	5,951

The death-rate from pulmonary consumption continued its moderate decrease; the great increase in the rates from cancer, apoplexy, paralysis, insanity, heart-diseases and Bright's disease is maintained. From child-birth and puerperal convulsions the deaths for the last ten years beginning in 1875 are 317, 296, 227, 242, 204, 211, 205, 191, 193, 159, with an increase in the population in that time of not quite twenty-five per cent., perhaps indicating a gratifying improvement in medical practice. The total number of violent deaths 1995, shows an increase from 831, the number in 1875, at very nearly the same rate as the increase in population; 112 were from burns and scalds, 39 from poison, 186 from railroad accidents, 426 from loss at sea and drowning, 3 from freezing, 31 from heat, 11 by homicide, 184 by suicide.

The number of deaths attributed to softening of the brain, apoplexy, paralysis, cephalalgia, and unspecified brain diseases has increased from 1,386 in 1860 to 3,669 in 1884, or at a rate *nearly two hundred per cent.* greater than the increase in the population. There can hardly be any assertion that any considerable part of this increase is due to improved diagnosis where the symptoms are so manifest, and it becomes a matter of great importance to ascertain how far it may arise from change in methods of living, immigration of poor stock or emigration of young active natives. The steady annual rise in the number of deaths from Bright's disease from 110 in 1870 to 619 in 1881, with an increase of only forty per cent. in the population, if partly or chiefly explainable by similar causes, must be largely due to greater accuracy in diagnosis. The highest mortality from Bright's disease is between the ages of 50 and 60.

There is a satisfactory improvement in the number of deaths from diarrheal diseases, which have diminished more or less steadily in ten years from 3,920 to 3,514 in face of an increase of about twenty-five per cent. in the population. In diphtheria, there has been an almost unbroken decrease since the height of the epidemic in 1876, but the mortality of the last two years was exceeded in each year from 1861 to 1865.

The mortality from pneumonia was .38 percent, less than the average for the past ten years, a little more

<sup>1</sup> Forty-third Registration Report, edited by Dr. Frank Wells.

than one-half the deaths occurring in children under five years of age and in old people over sixty. In the order of fatality, the months were December 378, January 320, March 320, November 306, February 299, April 264, May 197, October 161, June 124, July 99, September 97, August 81.

The year was, on the whole, a favorable one, from the point of view of the public health. The decrease in the mortality from diseases which boards of health can control must be a gratification to those who have worked in the cause of practical sanitary science, in which our defunct State Board of Health led the way. At the same time, the increase of diseases attributable to the less obvious faults and vices of concentrated populations in overwork, overcrowding, bad air, excesses of all kinds, and deterioration of stock is naturally a source of alarm, and suggests a hopeful result from labor among the young in that most fruitful field of effort, our public schools.

The report is a creditable one to the State and to its various editors whose intelligence and industry have made it what it is. We have always maintained, however, that there are manifest advantages in its being under the management of the State Board of Health, if we can have, as we now hope to have, an independent board worthy of the full support of the medical profession.

#### MEDICAL NOTES.

—A retailer of methylated spirits, in Glasgow, has been fined 20*l.* for each offence, having sold half-a-gallon of methylated spirits as a beverage, to two persons on the 9th of August last.

—A medical man in England recently objected to taking the judicial oath in the ordinary form to wit, by kissing the testament, on the score of uncleanness and risk of infection. The judge refused to entertain this as a "conscientious objection" within the meaning of the act. The witness at length complied under protest. One is inclined to sympathize strongly with the compunctions of the witness on reflecting upon the number and miscellaneous character of the osculations performed upon the volume in an average court-room.

—A correspondent of the *Philadelphia Press* recently visited the dwelling of a poor landlady in Montreal, where he found two children ill with small-pox, and a third, as yet well, playing around the same room. "Why don't you have that child vaccinated?" exclaimed the reporter. "Ah! non, non!" said the mother, and she snatched up the little one in an involuntary fear that the objectionable virus might be surreptitiously introduced beneath the tunic of her offspring. "Have the Board of Health been around?" "Yes, some one came and put up a notice." "Who pulled it down?" "Ah, je ne sais pas," replied the landlady. "Do you know the child is dying?" "Ah, yes, but I have to do the washing for madame's lodgers." "You don't mean to say that you are washing the clothes of an outside family?" "Oui, oui, arrangement."

#### BOSTON.

—An old man at the south end of Boston, grandfather of a girl who was recently admitted to the small-pox hospital, has run away. The Health officers visited the house to vaccinate all who had been exposed to the disease, but just before the old man's turn came, he disappeared, and all attempts to find him have failed. How often it happens that the health and welfare of a whole community lie at the mercy of a single fool.

—There is now only one patient in the small-pox hospital.

—We regret to note that a prominent gynecologist of Boston has been subjected to a suit for malpractice by a woman whom he treated gratuitously, the claim being made that he performed an operation upon her against her will, the operation itself being unnecessary and improper. Moreover, that she was discharged from the hospital where she had been treated, at an unsuitable time. She lays her damages against the physician at \$10,000, and for a like sum against the hospital. The amount of "solace" claimed suggests the possibility that in the future the lacerated uterus may prove a greater source of profit to the professional adventurers than the traditional lacerated affections have in the past. Meanwhile, the physician has our sincere sympathy.

—The Massachusetts Veterinary Association, a body composed of regularly graduated veterinary surgeons, all practising in Massachusetts, held its first meeting at the Medical Library a few days since. Its objects are the elevation of veterinary science, and it will apply for articles of incorporation the coming winter. The officers are: President, Dr. Frank S. Billings, of Boston, now of the Polyclinic School of Medicine, New York City; Secretary and Treasurer, L. H. Howard, D.V.S., of Boston; Executive Committee, W. Dryden, D.V.S., W. T. Simmons, D.V.S., and J. M. Skally, D.V.S., all of Boston. The paper read was by Dr. Billings on the subject of "Tuberculosis." He criticized the present methods of milk inspection, which included only an examination of the milk, and paid no attention to the source of the milk, to wit, the cow. The great frequency of phthisis was considered to be due to a considerable extent to the use of tuberculous milk. The disease has not been found at the actual time of birth, but has been detected in calves in cases of premature birth, and in calves three months of age and upwards. The bacilli have been repeatedly found in milk from cows that had tuberculosis. The disease has invariably been produced in young animals when they were fed with the milk of their mothers so affected. Among cattle, the Jerseys are the most afflicted with tuberculosis. The only way to find a remedy for this disease is by inquiry and observation into its cause and effect. The conclusion was a recommendation that the matter be taken in charge by a board appointed by the State.

## Miscellany.

### ON TUBERCULAR MILK.

THE *Therapeutic Gazette* (Oct. 15, 1885), contains the substance of remarks on this subject by Dr. Bang, of Copenhagen, speaking before the last International Medical Congress meeting of that city. He pointed out that milk taken from the tubercular cow is probably a fruitful cause of tuberculosis in children. It must be admitted that the etiology of tuberculosis is still an obscure subject. Hereditary transmission, malnutrition and confinement, are no doubt, powerful causative agencies, though scarcely able to account for all cases. The fact that milk is the principal factor in the nutrition of children, and that tuberculosis is of such frequent occurrence in the early phases of life, leads naturally to the consideration of the question whether or not milk be one of the etiological factors of tuberculosis.

Bang declares that tuberculosis of the udder of milk-cows is by no means a rare affection, and is characterized by a diffused painless swelling of one, rarely of two portions of the udder proceeding without any constitutional implication. A gland thus affected furnishes in the beginning an apparently perfectly normal milk, while in a simple non-tubercular inflammation the milk is at once materially and conspicuously altered. The affected portion of the gland grows larger and harder, while the unaffected portions gradually diminish in size. The diagnosis is corroborated by the swelling of the supramammary lymph gland. This milk, then, though looking perfectly normal, contains, according to Bang, a great number of tubercle-bacilli. The question whether such tubercular milk may infect domestic animals and man can be only definitely settled by feeding experiments, though *a priori* it would appear quite possible. Of Johne's ninety-one experiments, thirty gave positive, fifty-nine negative results, while Bang's own experiments on five pigs and three rabbits all gave positive results. Besides, Dr. Bang quotes the case of a calf infected by the milk of a tubercular cow. Tubercle-bacilli having been observed by the author in the milk coming from an apparently healthy udder, it is possible that the milk of a cow be tubercular and no local manifestation on the udder be present.

Fortunately, the experiments of Bang showed that boiling of the milk killed the bacilli in every case, hence it is but prudent to resort to this process in every doubtful sample of milk.

### A CASE OF HYSTERIA IN THE MALE SEX.

A REPORT concerning a case of aggravated hysteria in a boy of ten years is given in the *Archives of Pediatrics*, September 15, 1885, having originally appeared in the *Deutsch. Med. Wochenschrift*, 16, 1884. As to the patient's family history, his grandmother on his father's side was epileptic. The patient suffered painful sensations in the course of the trigeminal and other nerves. After a time there appeared irregular action of the muscles, unsteadiness of the intellect, incontinence of urine during the day, and within a year and a half pains in the head, vomiting, amblyopia in the right eye, and emaciation. By the end of another half year all these symptoms, with the exception of irritability and perverseness, had disappeared, and were followed by the following series,

drumming with the feet, dizzy sensations, emprosthotonus, with rapid forward movements of the body, and without loss of consciousness. These symptoms appeared in paroxysms for twelve days. On the thirteenth, in place of the tonic spasm, there appeared spasmodic shaking, spasms of laughter, hallucinations, and loss of consciousness, amaurosis of the right eye, paresis of the right arm. Six days later the blindness and the paralysis had disappeared, and a general hyperaesthesia was developed, then amaurosis of the left eye lasting twenty-four hours was added. About this time the boy was removed from the house of his parents to a public institution. In three days he was well, nothing remaining of his old trouble save a decided excitability.

### AN HISTORICAL INSTANCE OF ALLEGED LATE MENSTRUATION.

PROBABLY there is no more striking illustration of the truth that a man is incapable of judging alleged facts belonging to a department of knowledge which he has never studied, says the *Medical News*, than was given by Gibbon in regard to the death of Asima, the mother of Abdallah. The statement referred to is found in a note to the fifty-sixth chapter of "Decline and Fall of the Roman Empire." Abdallah had for months successfully sustained the siege of Mecca, but was finally compelled to yield, the city was taken, and he was slain. The tidings of his death were borne to Asima, and Gibbon states as a "physical effect of her grief for his death, the return at the age of ninety, and fatal consequences of her menses." The authority from whom Gibbon seems to have derived this remarkable statement was D'Herbelot; and, upon referring to his great work "Bibliothèque Orientale," 1777, it is found that this author not only asserts the return of menstruation in Asima in consequence of the profound emotion caused by her son's death, but that the flow proved fatal in five days.

Our contemporary remarks that a knowledge of human physiology would have saved Gibbon from accepting as a fact so marked a violation of physiological law. Such a flow as occurred in Asima's case was in no proper sense to be set down as menstruation—the very fact of its proving fatal would be an obvious objection, apart from any other, to accepting such view.

If so learned a man as Gibbon, one so little disposed to be credulous that he often leaned to incredulity, could repeat that which every intelligent physician would reject, it is not astonishing that the ignorant will accept the most absurd statements in regard to medical matters, and are so frequently made the prey of designing quacks. The narrative too, has a wider application, as indicated at the beginning of the note.

## Correspondence.

### ABUSES AND MISAPPLICATIONS OF MEDICAL CHARITY.

CHARITY ORGANIZATION OF THE CITY OF NEW YORK, CENTRAL OFFICE, 79 Fourth Ave., Nov. 6, 1885.

MR. EDITOR, Will you kindly give notice in your next issue, that in compliance with many requests from officers in charge of medical institutions, the Charity Organization Society invites the Medical Staffs and the Boards of Managers of the several hospitals and dispensaries of the city, to meet at the hall of the New York

Academy of Medicine, on Friday, November 20th, at 8 A.M., to confer together concerning the existing abuses and misapplication of medical charity, and to consider how these abuses may be remedied, through the registration system and other facilities of the Charity Organization Society. Yours very truly,

CHAS. D. KELLOGG,  
Organizing Secretary.

### COCAINE FOR TEETHING.

MR. EDITOR.—I cannot find that cocaine has been employed to any extent for the relief of the local tenderness in teething children, and should be glad to obtain the experience upon this point of any brother physician. Furthermore, whether any one has derived benefit from the internal administration, in such cases, of any preparation of the hypophosphites would be a piece of valuable information.

Very respectfully yours,

EDWARD WIGGLESWORTH, M.D.

BOSTON, November 7, 1885.

### DEATH FROM UNDELIVERED PLACENTA.— CASE OF MALPRACTICE.

UPTON, MASS., Nov. 7, 1885.

MR. EDITOR.—In your issue of November 5th, J. Alban Kite, M.D., gives a thrilling account of "death from undelivered placenta, case of malpractice." The evidence therein given under oath by C. D. Marsh, shows most lamentable ignorance and carelessness.

Unless such cases as this are brought to light, and the public informed that such practice is *not* the way educated physicians generally do, then this State will swarm with irregulars, quacks and medical tramps of every hue.

I, for one, thank Dr. Kite for ventilating this case, and hope that our Legislature will wake up to the necessity of protecting the people from danger and death at the hands of pretenders and medical frauds.

Yours respectfully,

JEROME WILMARTH, M.D.

### THE CLIMATIC TREATMENT OF PHTHISIS.

DENVER, COLORADO, Nov. 3, 1885.

MR. EDITOR.—If I had the time, and could occupy your valuable space *ad libitum*, I should like to discuss the conclusions of Dr. Harold Williams, which appeared in your issue of October 1st, with reference to: "The Climatic Treatment of Phtthisis." I will, however, by your permission, content myself with a brief notice of the fallacies, or instabilities upon which these conclusions are made to rest. It is indeed, true, that the opinions and published statements of climatologists can, on most every phase of this subject, be made to contradict each other; but that is no fair argument against a given statement of either fact or opinion, as the general tenor of the article in question would seem to assume. I have somewhere seen "one hundred and forty-four self contradictions in the Bible" ingeniously arrayed by some skeptic, who fancied he could convince himself or his readers of these "contradictions" by placing selected phrases in opposition to each other.

It is much to be regretted that the medical profession is not far enough along to be at harmony on this question of the "climatic treatment of phtthisis"; but the value of *climate* and *change* is none the less potent when they are given a reasonable chance to show their influence.

The trouble probably is that too much has heretofore been expected of climate *alone*, and too little has been known of the diseased conditions to be overcome. The writer of this article has strong hopes that some future perfected knowledge of the life, growth and *climate* of the bacilli of tubercle, studied with reference to the experience of invalids under varying atmospheric conditions, will effectually settle these many discrepancies harbored by medical men on the subject of climate and consumption. He is very willing to

submit all he has ever written on climate to such enlightened verdict, for he feels confident he will not be judged to have been very far from right, since the elimination of bacilli tuberculosis, with their source of life and conditions of growth, seems to have been most facilitated by those conditions of climate he has always upheld, chief of which are dryness, cold, sunshine and elevation.

But to return to Dr. Williams's conclusions—"who confers upon me the honor of stating that mine is 'the nearest approach to a theory' he has been able to find 'as to the effect of diminished pressure upon phthisical patients,'" and then goes on to quote that part of my argument<sup>1</sup> based upon the increased "rarefaction" of the air contained in the lungs *during inspiration*, which he attempts to combat *as the whole theory* without ever mentioning the last half the argument, that of increased "pressure" during expiration. To quote my own words, "But expiration follows, and it is during expiration that the respiratory muscles have the greater power—greater because the muscles of expiration are in their normal condition for activity when the thorax is distended, and the thorax is *more distended* because it has to labor with more air."

It is not my purpose to dwell upon the consequences of this rarefied air process—the quickening and correction of pulmonary circulation of both blood and air, and the increased elimination of carbonic acid and the results of disease—but simply to show that my "theory" was not overthrown because it was not considered.

Again, Dr. Williams states that the advocates of high altitudes have not "given sufficient reasons for upholding their belief in the importance of dryness." He is respectfully referred to the writer's report on "Dryness," made to the Am. Climatological Association in 1884.<sup>2</sup> The argument based upon atmospheric dryness rests chiefly on the innocuousness of low temperatures, with a low relative humidity as compared with similar temperatures and a high per cent. of saturation, and on the augmented exhalation of moisture from the lungs, the air going in at a low and coming out at a high per cent. of saturation, and so producing an increased throwing off of inflammatory products, bacilli, etc.

Not being willing to admit the beneficial influence of dryness, which renders considerable changes in temperature comparatively innocuous, Dr. Williams sticks to the old hobby of *equability* in temperature, which, since the air of the sea is generally damp, is a favorable factor for that kind of air. But equability, being governed by atmospheric humidity, must necessarily cease to be the criterion by which to judge of the driest and sunniest health resorts, since these, in the United States, generally give the greatest mean daily and monthly variations in temperature.<sup>3</sup> The "shocks to the nervous system," and ill-effects of daily temperature changes, are unreasonably harped upon by the advocates of seaside resorts when speaking of the dry interior and unusually elevated sanatoria. A great change at the latter places is not more perceptible than a small thermometric change at the former, because of the difference in atmospheric humidity. This is a common experience with residents of Colorado.

As to the electric state of the atmosphere and favorable conditions for living out of doors in elevated sections, we can only account for the perversions of evidence which Dr. Williams shows in his paper, by a determination to believe in nothing, except that kind of climate which is now "knocked out" by his peculiar method of combat, namely, sea-air. As to his statement that mountain air, because the temperature is lower, "is opposed to the principles of hygiene in so far as it admits of less open-air exercise and prevents a suitable ventilation of the houses," there could

<sup>1</sup>The Rocky Mountain Health Resorts. An analytical study of Elevations, with reference to the cure of Chronic Pulmonary Diseases. Houghton, Mifflin & Co., Boston, Publishers. 8vo, pp. 91 to 94. 2d Edition.

<sup>2</sup>"Moisture and Dryness" with eight Signal Service Humidity and Cloudiness Charts of the United States. Rand, McNally & Co., Chicago.

<sup>3</sup>See "Moisture and Dryness," already mentioned, or the Border Tables, on either the Author's Annual or Seasonal Climate Maps of the United States. Rand, McNally & Co., Chicago.

be nothing more misleading; for the evidence of all the physicians from Cheyenne, Wyoming, south through Colorado, and around through New Mexico and Arizona, would be that, despite the cooler temperature and the uniformly cold nights, due to elevation, no section of country half so large has a climate comparable with this for the time that can be healthfully spent out of doors. As to the "prevalence of winds" among the mountains it is as well to bear in mind that the fourteen windiest places, according to the reports of the 136 signal stations in the United States since their establishment, are on the coast, excepting the exposed Pikes Peak and Mt. Washington stations.

I think the statement that the sea air is "purer" than the mountain air is erroneous, for you can rise in the latter till its purity becomes absolute, while in the former you

will have to go north or south till you reach the regions of almost perpetual congelation to find the same absolute freedom from germs. This is in accordance with the analysis of the air made by Professor Miquel at the Observatoire de Montsouris near Paris, who found less germs in the air (namely, none at all), at six thousand feet above sea level than in the air out at sea.

In conclusion, I will suggest to Dr. Harold Williams, and to all others who, like him, are sceptical as to what Colorado, New Mexico, and Arizona can do for phthisical invalids, to visit these sections and personally examine what the evidence is worth, which is deemed by physicians hereabouts to be so conclusive.

Respectfully yours,

CHARLES DENISON, M.D.

86 Massachusetts Towns . . . . .	—	—	—	—	—	—	—	—

Deaths reported 1,143; under five years of age 462; principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fever, and diarrheal diseases) 256, consumption 220, lung diseases 123, diphtheria and croup 115, diarrheal diseases 52, typhoid fever 40, malarial fever 17, scarlet fever 13, cerebro-spinal meningitis seven, whooping-cough seven, puerperal fever three, measles two. From malarial fever, New York eight, Baltimore four, Philadelphia and Charleston two each, New Haven one. From scarlet fever, New York and Philadelphia four each, Boston three, Providence and Salem one each. From cerebro-spinal meningitis, New York three, Fall River two, Philadelphia and Baltimore one each. From whooping-cough, New York four, Philadelphia, Charleston and Boston one each. From puerperal fever, New York two, Boston one. From measles, New York and Providence one each.

In 101 cities and towns of Massachusetts, with a population of 1,228,045 (population of the State 1,911,465), the total death-rate for the week was 15.08 against 11.38 and 15.57 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,986,146, for the week ending October 10th, the death-rate was 17.6. Deaths reported 3,011; infants under one year of age 829; deaths in London 1,300, acute diseases of the respiratory organs (London) 231, diarrhoea 37, whooping-cough 51, scarlet fever 19, fever 42, measles 38, diphtheria 21, small-pox (London) two.

The death-rates ranged from 1.8 in Wolverhampton to 28.1 in Preston; Birmingham 15.6, Blackburn 14.8, Hull 16.8, Leeds 17.7, Leicester 13.8, Liverpool 22.5, London 16.7, Manchester 22.7, Nottingham 51.4.

In Edinburgh 11.4, Glasgow 19.6, Dublin 21.1.

For the week ending October 10th, in the Swiss towns, there were 24 deaths from consumption, diarrheal diseases 17, lung diseases 12, whooping-cough three, typhoid fever three, diphtheria and croup two.

The death-rates were, at Geneva 13.2, Zurich 5.8, Basle 16.6, Berne 25.1.

The meteorological record for week ending October 31st, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole of the United States Signal Corps:—

Week ending	Barometer.	Thermometer.			Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall.

## Original Articles.

ON DEATH BY DROWNING.<sup>1</sup>

BY F. W. DRAFFER, M.D.,

Assistant Professor of Legal Medicine in Harvard College.

THE discovery of a dead body floating in the water, or cast upon the shore, presents to the medical examiner four problems for his solution:

- I. The identification of the person dead.
- II. The cause of the death.
- III. The manner of the death.
- IV. The interval since death.

I propose to discuss these topics very briefly in the light of my own observations during the past eight years. This experience has had as its material the personal inspection of one hundred and forty-nine dead bodies rescued from the harbor, river and other open waters abounding in Suffolk county, or cast upon the land after having been in the water, or found in tanks, privy-vaults, bath-tubs and the like, after domestic submersion. Of this number one hundred and twenty-four were males and twenty-five were females. All ages were represented, from the new-born infant, at one extreme, to the melancholy veteran of seventy-five at the other; but nearly all were under fifty years old. As would be expected, the influence of season showed itself in the fact that a majority of the inspections occurred between May and November, the deaths predominating then because accidents incidental to bathing and sailing are then most common, and because the bodies of persons perishing by submersion during the winter months appear subsequently for the first time when the ice has gone and putrefaction brings them to view as the warmer days approach.

The first question which confronts the medical examiner when he is called to view a dead body recovered from the water is, "Who is this person?" Occasionally it is a question of much difficulty and requires considerable attention. Like other floating material, a dead human body may be borne upon a stream or by the tide many miles from its point of departure, and identification may thus be rendered increasingly difficult by distance. In March, 1879, a boy was accidentally drowned in a creek in Waltham; twenty-seven days later his body was found on the South shore of the Charles River in Boston, ten miles away from the scene of the drowning. Again, time is an element of importance in facilitating identification. Putrefactive changes speedily destroy the facial characteristics and render recognition by the features impossible. But, fortunately, these cases which have to be recorded as "unknown" are very few. The friends of missing persons are on the alert to see all dead bodies which the newspapers announce to have been found, and generally the clothing and personal effects afford a ready means of identification. Of the one hundred and forty-nine dead bodies forming the basis of this paper, only twelve were buried unidentified, leaving out of the account the bodies of new-born infants thrown into the water after premature birth or still-birth.

Sometimes attention to seemingly trifling details in the description of dead bodies and their clothing is repaid by speedy and positive identification. For example, on one occasion, the dead body of a laboring man,

accidentally drowned in the course of a drinking-bout, was recovered after many days in a thoroughly decomposed condition; into the published description of the clothing, I inserted the small matter that one of the shoes was laced with an ordinary shoe-string, while the other was provided with a piece of white cotton twine as a lacing; this peculiarity attracted the notice of the dead man's relatives and led to the prompt recognition of the body. In another instance, a woman's body was brought to the morgue; on her back was a square of belladonna plaster, marked on the outside with the letter and number of a hospital bed and ward; this therapeutic clue served readily to establish the identity. The value of clothing as a means of identification was illustrated, in a negative way, in a case of a man whose body was forced by the tide under one of the wharves which skirt the city's water-front: the body was nude, and though a full description of its characteristics was published, and a sufficient time and opportunity were allowed for its inspection, no one appeared who was able to state the name and home of the unfortunate bather.

But the really important question for our study to-day is the purely medico-legal problem—the *post-mortem* diagnosis of death by drowning. When a dead body is found in the water, the presumption is that the water was the cause of the death and that the person perished by submersion. To verify or refute that presumption by an inspection and autopsy of the body is, under some circumstances, a most responsible and delicate duty. The question is sufficiently easy and simple if the death was recent and the body presents none of the changes due to putrefaction; it is difficult and presently becomes impossible of solution in proportion to the advance of cadaveric decomposition.

Upon a body twenty-four hours after death by drowning, the demonstration of fatal asphyxia by submersion is a satisfactory medico-legal study, with rare exceptions; twice twenty-four hours later, the most valuable and trustworthy signs may have wholly retreated before the skirmish-line of putrefaction. That these fortunately fresh bodies constitute a small fraction of the material offered to the medical examiner for his investigation, the experience of all of us readily attests. Commonly, we are confronted with the hideously inflated, horribly distorted, nauseously infected cadaver, whose stench fills our nostrils and our memories for many days; or we view with any other than the æsthetic sense, the remnant of mortality rescued from the sea, the skull bereft of its natural covering, the eyes long ago gone from their sockets, the nose and the lips likewise departed and exposing a grinning display of teeth, the hands, like the other accessible soft parts, appropriated by the fishes for nutritive purposes; but the clothing and every pocket and fold thereof alive with all manner of skipping and wriggling and slimy marine parasites, rendering a faithful search for the "money and other valuables" mentioned in the law, a critical test of the medical examiner's zeal. Such subjects, vulgarly called "floaters," may well lie under the presumption that they died in and by the water from which they were taken, unless an obvious external lesion, like a pistol-shot wound or a fracture of the skull, is observed upon the body and leads to another course of inquiry and to the demonstration of another cause of death.

What, now, are the *post-mortem* appearances which the examiner may rely upon for a diagnosis of death

<sup>1</sup> Read before the Mass. Medico-Legal Society, June 2, 1885.

by drowning? In the first place, what external indications are of value, assuming that the body under inspection is that of a person who, in drowning, came to the surface at least once before final submersion, that the interval since death is brief, and that the recovery from the water was but a little time before the examination?

The sign which I regard as of the first importance, superior to all others, is the presence of froth at the mouth and nostrils. When it is present in its typical development, it affords, in my belief, sufficient evidence to establish by itself the cause of the death. It is to be distinguished from the coarser gaseous bubbles which putrefaction brings to view at the lips and which the old women who "lay out" corpses note with interest; it is fine, light and delicate, like the foamy lather of the best shaving soap. Sometimes it has a pink tinge, and occasionally a distinctly marked red color, from the blood which has become intimately mixed with it in the course of its formation in the air-passages. It is found after drowning in any kind of fluid and under all circumstances (with the possible exception of cases in which the person drowning sank immediately without once returning to the surface for air, although of this exception some excellent authorities express doubt.) I remember to have seen it very fully developed in the case of a child who was drowned in a privy-vault. It is a very evanescent sign and may not be expected after an interval of four days after death in winter and of sixty hours in summer. Its appearance externally is due to its escape and overflow from the trachea and bronchi where its primary formation occurs.

The color and condition of the skin are of interest. In the recently drowned body, promptly recovered from the water, the condition of the skin so far as lividity is concerned, is not remarkable over regions situated below the clavicles; the face is either deeply injected so that it presents a mottled purplish color, with marked reddening of the conjunctivæ and engorgement of the ears and lips, or there is a dull sodden lividity; or, not uncommonly, there is the same pallor which characterizes the rest of the body. Whatever the hue may be at the outset, it does not persist, but a significant change presently occurs. After an interval varying from a day and a half to four days (or even later in winter), the face, without being swollen, as at a later stage when decomposition is fully in progress, assumes a uniform, dull red or copper color, not mottled or in streaks, but equally distributed. Ogston explains this change as arising from the action of the oxygen in the air or the water, but the precise nature of the process he does not make clear. A little later, but long before the rest of the body, protected by the wet clothing, shows any alteration, the face becomes swollen and distorted, the lips protrude, and the eyelids are distended, in consequence of the advance of decomposition.

*Cutis asserina*, which generally observed upon the bodies of the drowned which have come under my inspection, has, in my belief, very little diagnostic value. Its presence indicates a vital reaction in the skin, but not necessarily caused by contact of cold water with the skin. Casper<sup>2</sup> ascribes its formation to mental shock rather than to the effect of cold on the body, and he states that he has observed it upon those drowned in the heat of summer, and frequently,

also, upon those who have died otherwise than by drowning, though by violence, as by shooting, hanging, stabbing, falls and the like.

The blanching and wrinkling of the skin of the hands and feet and knees, formerly set down as among the signs of death from drowning, are now recognized as simply the physical effect of water upon the cutaneous tissues, whether living or dead.

It has not been my fortune to observe that important sign of drowning—the presence of substances grasped in the hands. Where this evidence exists, it is unquestionably a very valuable aid to diagnosis, providing the matters found in the hands are identical with those growing or floating in the water, and provided, also, the grasp of the hands upon these substances is the grip of cadaveric spasm indicating a vital act. The same rule holds here as in other cases of instantaneous rigidity: that the closure of the hand upon its contents must be more than a mere flexion of the fingers; it must be a true death-grip to give it value as a post-mortem sign.

The situation of the tongue is insisted on by some authors as important, and the examiner is advised to note whether it is engaged and more or less protruded between the teeth, or is in its normal place. In nearly every instance in which I have recorded a note on this point, the tongue has been observed in its normal relation to the teeth; in a few cases, its tip has been found engaged between the teeth, and sometimes it has been swollen and closely apposed to the palate. I have never seen it protruded between the lips.

Let us turn, now, to the appearances which the internal examination reveals. Upon raising the sternum, after the primary longitudinal incision, the increased volume of the lungs at once arrests attention. The organs are fully expanded so as almost to conceal the pericardium. They do not retract when the sternum is lifted, but they bulge forward into, and, to some extent, through the exposed space. This appearance is described by Casper as "truly thanatognomonic," and he explains it as "in part an actual hyperæmia in consequence of very violent inspiratory acts carried on at the momentary emergences of the head of the drowning person above the surface of the water, and partly (and chiefly), in consequence of the inhalation into the lungs of the fluid in which the drowning has occurred." Dr. Ogston has attributed this condition to the presence of water or watery fluid in the pleural cavities; and the protrusion of the lungs is caused, in his opinion, by the buoyant organs floating above this fluid when the controlling pressure of the sternum is removed. This does not seem to me to be an adequate explanation, since in many cases in which I have observed the appearance to a marked degree, the amount of fluid in the pleural cavities was small, wholly insufficient indeed, to float the lungs.

To the touch, as well as to the sight, the lungs present characteristic indications. They feel like edematous tissues, pitting on pressure. They show sometimes, the oblique impress of the ribs.

Careful inspection discovers the air-vesicles to be fully distended at the surface of the organs, and quite extensive areas of ruptured cells are sometimes seen under the pleura, as in emphysema.

The external color of the lungs is not uniform, according to my observation. Sometimes, the organs are of a pale gray color, both anteriorly and posteriorly; more frequently, hypostatic reddening is seen, the an-

<sup>2</sup> *Handbook of Forensic Medicine* (Sydenham Ed.), II, 231.

terior parts remaining pale. In other cases, where the subject is plethoric, the entire pulmonary surface has a red or purplish hue. Much depends on the individual habit, on the interval since death, and on the position of the body in the interval. I remember one case which illustrates the influence of blood-supply. A woman committed suicide by drowning while in a condition of melancholia, induced by the progressive growth of uterine fibroids, which she regarded as incurable; they had caused repeated and profuse hemorrhages, so that at the time of her death she was very anæmic. The lungs presented, on post-mortem examination, a singularly pale appearance throughout, the amount of blood in the body being insufficient to give to those organs any marked reddening, either superficially or upon the cut surfaces.

In the majority of my cases, I have observed punctate sub-pleural ecchymoses, generally few in number and situated in the lower parts of the lungs, and most frequently, in the fissures between the lobes. They vary in size, the largest scarcely exceeding the size of a millet seed.

Upon section, the lungs almost invariably show clear indications of death by submersion. These indications include a more or less intense reddening of the pulmonary tissue; the abundant saturation of the lung with fluid which escapes, as in œdema, on the slightest pressure, from the entire cut surface; and the presence of froth and fluid in the air-passages from the trachea onward to the smallest bronchioles. In a few instances, I have found sand or mud in the trachea and larger bronchial branches. When the body has been recovered early from the water, I have regarded these evidences of the penetration of water and other foreign matters into the respiratory passages as valuable diagnostic indications; but the interpretation of these appearances as signs of vital acts, should, in my belief, be guarded, since we know experimentally that water may penetrate the ultimate structure of the lungs when a dead body is left sufficiently long and in a favorable position in the fluid. But if, with the water, I have found in the air-passages, the fine, foamy froth previously described, I have not been left in doubt concerning the cause of the death, since it is impossible to explain the formation of this product in any other way than by the violent respiratory acts of the person submerged; it is a sufficient proof that the body, now dead, was alive when it entered the water.

The heart has almost constantly been found in a condition indicating death by asphyxia; its right cavities have been filled with blood, its left ventricle being generally contracted and empty. The condition of the heart in this respect was in harmony with the hyperæmia of the lungs usually present and due to the same cause.

The blood has always been found of a dark color, and generally of fluid consistency. In rare instances, I have observed clots in the right ventricle, but they were small, ragged and soft.

The appearances about the abdominal group of organs I believe to be of slight diagnostic importance. One generally finds the vessels of the peritoneum and mesentery fully injected, and engorgement of the spleen, kidneys and liver, consistent with the asphyxia, which was the predominant factor in the cause of the death.

The presence of water in the stomach has been deemed by some authors a sign of much value in the

determination of death by drowning, indicating that the fluid was swallowed in the course of the submersion. When the stomach contains water or other fluid or material identical with that in which the body was found (a matter sometimes of difficulty to determine), it is clearly a very trustworthy evidence, since we know experimentally and upon good anatomical and physiological grounds that water does not penetrate to the stomach of the dead subject, and, hence, that its presence there is a proof of vital action. Thus, when we find salt water, or dock mud, or bits of sea-weed in the stomach, we recognize a good confirmatory sign of death by drowning. But one is not always fortunate in discovering this sign; in many of my cases, the stomach has been found either empty or containing food with very little fluid. In one case of suicidal drowning, a pint and a half of quite clear water was noted; in another case, twenty fluid ounces of watery fluid, mixed with mud, betokened the act of swallowing in the course of the drowning. Where drowning occurs in clear, fresh water, it would require a very nice discrimination to set aside the possibility that the water contained in the stomach had not been voluntarily taken to satisfy thirst a short time before the submersion.

In about half my cases, I have observed a marked injection of the meningeal vessels and appearances indicative of hyperæmia of the brain; but I have not regarded this as among the more reliable guides to a post-mortem diagnosis, since cerebral congestion may result from so many conditions immediately antecedent to drowning but wholly independent of that act.

Now, if I should summarize the various anatomical proofs of death by submersion which my experience and study have taught me to regard as most trustworthy, I should state them thus. They fall naturally into two groups, namely, those indicating the generic cause of death (asphyxia) and, secondly, those especially showing that the death was by submersion. Of the former class of signs, the distended right cavities of the heart, the engorged lungs, the subpleural punctate ecchymoses, the evidences of hyperæmia in the liver, spleen and kidneys, and to some extent also in the brain and its meninges, the reddening of the tracheal and bronchial mucous membrane, the dark, un-oxygenated color and the fluid condition of the blood readily occur to mind as almost uniformly present. Of the second or specific group of proofs that the asphyxia was the result of submersion, I name the following as the more important: Froth at the lips and nostrils and in the trachea and bronchi; water in the bronchi either with or without mud and other foreign matters; extreme distension of the lungs; superficial pulmonary emphysema; water in the small bronchioles and in the vesicular structure as shown on the free escape of the fluid from the cut surface of the lung; thin, clear fluid in the pleural cavities; water, particularly muddy water, in the stomach. As confirmatory signs I would mention *cutis anserina*; the presence of objects held firmly in the hands and clearly derived from the water in which the body was found; blanching of the skin of the palms and soles; marked lividity of the face, with injection of the conjunctivæ.

Close upon the determination of the cause of the death, follows the scarcely less important medico-legal question, its manner. Was the life destroyed with suicidal purpose, or by homicidal violence, or was it lost accidentally. It must be admitted that the solu-

tion of this problem is in great measure a police rather than a medical matter. The phenomena of drowning do not differ materially whether their subject falls into the water, or jumps in, or is pushed or thrown in; and the anatomical appearances, both internal and external, are not susceptible of differentiation from that point of view. The material circumstances of the death, upon which almost wholly a decision concerning its manner must rest, though falling outside a strictly limited medical examination, may nevertheless come to the medical examiner's knowledge through the statements of eye-witnesses; or they may be inferred with sufficient accuracy from the condition of the body when found. Thus, the discovery of a naked body in the water, in summer, leaves little doubt that accidental drowning occurred while the person was bathing; while suicide is reasonably to be inferred when the examiner's search through the clothing is rewarded with the discovery of stones or other heavy objects in the pockets, or when he finds, as in one of my own cases, a flat-iron tied to one of the ankles. Homicidal violence by drowning is a more difficult matter. It is true that this form of homicide is of the rarest possible occurrence, and that the chances that death in any given case was either by accident or suicide greatly preponderate; yet the examiner should not allow himself to be misled by the doctrine of chances, but he should be on the alert perpetually for evidences of crime. These evidences, so far as the anatomical appearances go, are to be found in the presence of lesions indicating resistance. But there is need of caution even here, as one or two illustrations may serve to show. In one case to which I was summoned, the body of a German brewer was found in a large tank in the basement of a brewery; entrance to this reservoir was possible only through a chute or shaft, about two feet square, leading from an upper story. The body showed unequivocal indications of death by drowning; but in addition, there were contusions upon the face and scalp not easily to be explained by the fall through the shaft. It would have been easy to entertain the theory that the man had become engaged in a quarrel with one of his fellow-workmen and had been thrown down the shaft into the water when disabled by the blows on his head. But investigation demonstrated that the ecchymoses about the head were the result of blows received two days before the death in the course of an altercation in a beer-saloon, and letters were found which indicated that the mortification growing out of the punishment which he had received from his opponent was one of the incentives which led the man to drown himself. In another instance, the body of a man was found floating in Charles River. At the inspection, I found behind the ear a contused wound of the shape of the letter H, the longest part of the wound measuring an inch and three-quarters, and its deepest part penetrating to the skull. It was such a wound as a blow with a rough stone or some similar weapon could have made, and its appearances clearly indicated that it was received before death; the skull was not fractured. The other anatomical appearances were those of death by drowning, and the inference was reasonable that the man might have been assaulted, struck heavily on the head and thrown into the water while incapable of resistance. For a month the man's identity remained unknown; and thus the facts relating to his death were also hidden. But, at length, the woman with whom he had lodged identified

his clothing and stated that two days before his body was found, he had come home late at night, very drunk, with his head wounded and bleeding and his clothing much stained with blood, appearances which were caused, according to his story, by his falling down some stone steps. It was learned that, in the course of this latest inebriety he was discharged from his usual place of work, and the fair conclusion was that, being out of money and out of employment, he destroyed himself in the despondency resulting from his financial and alcoholic misery.

Thus the signs of violence are not to be hastily interpreted. Moreover, the additional caution is to be borne in mind that under certain circumstances wounds found upon the bodies of the drowned are the results of injuries received by striking upon jutting rocks or upon bridge-timbers; or were produced upon the dead body in the efforts to recover it from the water. On the other hand, it is not to be forgotten that the entire absence of marks of violence upon the body of a person drowned is not inconsistent with the fact, otherwise established, that the death was by homicide: a man overcome suddenly by more than one assailant, and, by garroting, made incapable of self-defence; a woman similarly overpowered by muffling her head in a shawl to stifle her cries; a child without any such preparation for a violent death, all these might easily be tossed into the water and their dead bodies would reveal to the medical examiner the signs of death by drowning only.

Among the cases of accidental or suicidal drowning that have come under my notice, one or two deserve a word on account of their peculiarities. A man, in low spirits as the result of intemperance, tried ineffectually to obtain a supply of laudanum one midnight under false pretences, and in the morning was found dead in his bath-tub, with only his underclothing on his body, and with his head immersed deeply in a pail of water in front of which he was kneeling. A child, two years old, was left alone in a room in which was a large butter-tub containing five inches of water; after five minutes' absence, the mother returned to find her child head downward in the tub and dead by drowning.

Of the one hundred and forty-nine cases which have supplied the basis of this paper, ninety-two were cases of accidental drowning; and of these ninety-two, twenty-one were bathing casualties, chiefly among boys under fifteen years old. The sudden and furious tempest of July 16, 1879, occurring while many pleasure parties were sailing in the harbor, yielded thirteen of these victims of accidental drowning.

A common and natural question addressed to the medical examiner as he stands over a dead body just brought to land, is "How long has this body been in the water?" Certain writers on legal medicine declare their ready ability to determine this problem by means of the phenomena of progressive putrefaction which the body presents. I have studied this point with considerable care and I confess that the practical fruits of my study are unsatisfactory. I cannot answer the question with any degree of precision except within very narrow limits. In a case of death by drowning, the circumstances of which are wholly conjectural at the time of the inspection, one can say with sufficient confidence, this death occurred within twelve hours, or yesterday, or the day before yesterday; but I contend that one is using his guessing privileges unscrupulously when he tells the reporters, with an affectation of can-

dor, that the drowning occurred a month ago, or six weeks ago, or ten days ago; he really does not know and cannot know with the anatomical appearances as his only guide. I offer one or two instances in illustration. Among the victims of the gale above mentioned, were three men, of nearly the same age and physical condition, and, so far as is known, exposed to identical post-mortem influences; two of the bodies were recovered July 27, eleven days after the storm, and the third was brought ashore two days later; in all three of these, the appearances were the same as Devergie describes as proper for dead bodies recovered three and a half months after submersion, the most striking feature being the entire loss of the soft parts from the skull and from the hands. In another instance, a party of young men were sailing May 30, 1883, and two of their number, H. and B., aged twenty and twenty-one, were drowned by the swamping of their yacht; the body of H. was recovered June 21, and that of his comrade came ashore June 22d, or, respectively, twenty-two and twenty-three days after death. In the case of H., all the soft parts of the head and face were cleanly removed, and both hands were gone; while in the case of B., besides the loss of both hands, the head was missing and the cervical vertebrae were as clean as if they had been macerated and artificially articulated; the skin of the abdomen was adipoceros. These examples serve to teach us caution; they recall the fact that the problem is not a simple one and that, if the processes of putrefaction have begun their work upon the body under inspection, a considerable degree of reserve is requisite in its answer. These views are in harmony with Casper's observations touching the conditions "of which, as yet, we know nothing," which modify the advance of decomposition, and the case which he cites to demonstrate this is sufficiently convincing. "On the 20th of March, 1848," he writes,<sup>3</sup> "I examined the bodies of fourteen, almost all of the same age, twenty-four to thirty years, previously occupying the same social position, all lying together in the same part of our dead-house, who had all met the same death, having been shot on the barricades on the 18th of March, and had all died at the same time. Here there certainly existed those identical conditions so necessary for instituting a comparison, and yet I can testify that in no one case did the signs of putrefaction resemble those of another." With such an authority to teach us moderation, it well becomes us to avoid dogmatic assertions about matters of uncertainty.

—Consular reports show that during the week ending November 4, there were 233 deaths from small-pox in Montreal, and 89 in adjacent municipalities. In Toronto one death occurred October 28, the first from the disease in the city. Kingston is free from the disease.

—According to the last United States census there are 563 establishments in this country devoted to the proprietary medicine business, employing 1,015 operatives, with an aggregate investment of capital amounting to 10,620,000 dollars, and the annual product is valued at 14,682,000 dollars.

UNIFORMLY CONTRACTED, NON-RACHITIC PELVIS. THREE SUCCESSIVE PREGNANCIES TERMINATED RESPECTIVELY BY PREMATURE DELIVERY, VERSION AND FORCEPS. FRACTURE OF THE COCCYX.<sup>1</sup>

BY F. H. LOMBARD, M.D.

MARCH 1st, 1885, I was called in consultation by Dr. J. W. Elliot, to see a patient then in labor whose history briefly is as follows:

Mrs. C., age thirty-six, III para. Born in Halifax, N. S., of English parents. Father died of Bright's Disease of the kidneys. Mother living. Was a seven months baby, the fourth of fourteen children. Learned to walk at nine months, had none of the usual diseases of childhood. Catamenia appeared in thirteenth year. After one year she became regular and has continued so ever since. Menstruation every four weeks, four to five days, abundant. Slight dysmenorrhœa. Was married in September 1878, when twenty-nine years old. August 22d, 1879, after a labor lasting ten hours, gave birth to a seven months child that weighed at birth five pounds, and lived twenty-six days.

March 19th, 1881, Dr. A. T. Cabot, with Dr. W. L. Richardson in consultation, delivered her at full term of a male child weighing eight and a half pounds.

The account of this confinement, which was of extreme interest, was published in full by Dr. Cabot in the *Boston Medical and Surgical Journal* of October 5th, 1882, from which I quote the following extracts:

"Waters broke at the outset, and after twelve hours of good pains, the head had not engaged in the pelvis. Version by Dr. Cabot, assisted by Dr. Richardson. Trunk and arms easily delivered, but the head became arrested at the brim. Forceps to the after-coming head, and as strong traction as possible. Delivery at the end of what seemed to be ten minutes. The child, apparently dead, revived after fifteen minutes of artificial respiration, and still lives. The mother's convalescence was uninterrupted good until the thirteenth day, when the appearance of a sudden chill led to the discovery of a peri-epi-uric abscess, from which she recovered slowly."

I first saw the patient with Dr. Elliot, on Sunday, March 1st, 1885, and learned the following details. On the Tuesday previous the membranes ruptured suddenly as she was getting out of bed, and quite a gush of water came away. From that time there was occasional dribbling of amniotic fluid and intermittent pains. Active pains began at midnight, February 28th, and continued strong and frequent through the following (Sunday) morning.

The head which was presenting would not, however, engage in the pelvis, and as the os dilated very slowly, and the patient began to show signs of exhaustion, the question of etherizing, dilating the os and turning, was entertained.

Under the effect of chloral, however, pains became less frequent and more effective, and at the time of my visit at 3 P. M., the os was three-fourths dilated and the head in the position O. L. A. was well down in the pelvic cavity and fixed.

The outlet of the pelvis was felt on examination to be narrowed both in the transverse and the antero-posterior diameters, the tubera ischii being abnormally

<sup>1</sup> Read by invitation before the Obstetrical Society of Boston, April 11th, 1885.

<sup>3</sup> Handbook of Forensic Medicine (Sydenham Ed.) I, page 32.

near together, and the finger impinging at once upon the coccyx as soon as it entered the vagina.

It was agreed that ether should be given and the forceps applied at once without awaiting complete dilatation of the os. This was done, and as much traction as possible employed. The head, which was small, advanced slowly until it reached the outlet. At this point, the projecting coccyx could be felt grasping the head like a claw, and indenting the scalp. To drag the head by this without fracturing the coccyx was impossible. It snapped with a dull sort of click that was distinctly felt and heard. The head was then delivered without difficulty, the perineum sustaining a very slight tear to the right of the median line, not enough to require sutures. The child was a girl.

Weight 7 lbs.	
Length	51 cm. = 20 in.
Largest circ. of head,	37 " = 14 1/2 "
Occipito Frontal diam.,	11 " = 4 1/2 "
Occipito Mental,	13 " = 5 "
Sub-Occipito Bregmatic,	8 " = 3 1/4 "

Placenta was expelled in ten minutes. Vaginal examination, while the patient was still under ether, showed that separation of the coccyx had taken place at its junction with the sacrum. No crepitus could be detected, and although the detached fragment was freely movable, there was little displacement.

Convalescence was perfectly normal and free from pain. I examined the patient yesterday morning and took the following measurements:

	Maximum weight, 104 lbs.	Normal.	Mrs. C.
Height,	161	143 cm. = 4 ft. 8 1/2 in.	
Circ. of Pelvis,	30	74 "	
Iliac Crests,	28	22 "	
Ant. Iliac Spines,	25	19 "	
Trochanters,	33	25 "	
Ext. Conjugate,	18-20	16 "	
Diag. Conjugate,	13	9 "	
True Conjugate,	11	7 "	
(It. Ext. Oblique,	22	20 "	
(It. " "	22	20 "	
N. B. Tip of Coccyx to			
Pubic Arch,	9.5	6.5 "	
Height of Pubes,	5	5 "	
Post. Sup. Spines,	11	11 "	
Tub. Ischii,	11	6.5 "	

This, then, was a case of uniformly contracted, non-rachitic pelvis. That it was non-rachitic is shown by the fact that the normal relationship between the iliac spines and crests was preserved. Also, there was nothing in the history or the development of the patient pointing to rachitis. That it was a uniformly contracted and not simply a flattened pelvis is shown by the shortening in the transverse as well as the antero-posterior diameters of both inlet and outlet. While the true conjugate of the inlet was reduced from 11 centimeters to 7, and of the outlet, from 9.5 centimeters to 6.5, the distance between the crests, iliac spines and trochanters were reduced from 28, 25 and 33 centimeters to 22, 19 and 25, respectively, and the distance between the tubera-ischii was reduced from 11 centimeters to 6.5.

As to the aetiology. It seems to have been simply a case of incomplete development. She was born at the seventh month. Her form was perfect in every particular, and the pelvis simply kept pace with the rest of the skeleton, which was perfect in every part, but fashioned on a small scale. This pelvis, therefore, was not one of those that preserve their infantile shape in adult life, with straight sacrum, slightly developed alae of the ilia, acute-angled pubic arch, etc. On the contrary, at puberty it broadened out to the best of its ability, and in adult life showed the perfect proportions of an adult pelvis, but of diminutive size.

The chief points of obstetric interest attaching to the third confinement are:

1. Early rupture of the membranes.
2. The question as to the advisability of performing version or delivery with high forceps.
3. Fracture of the coccyx.
4. The fact that adopting the forceps as the method of delivery furnished an opportunity of comparing the results of the three methods—premature delivery, version, and forceps—as exemplified in successive labors in the same pelvis.

The early rupture of the membranes would have added to the difficulties of turning had this been decided upon.

As to the question of preference between high forceps and version, this has been pretty unanimously decided in favor of the latter, the grounds for this preference being too well-known to need mention here.

The fracture of the coccyx was unavoidable, and it would have been as serious an obstacle to the after-coming head as to the head in advance. It was attended by no ill results to the mother, who would not have known of its occurrence had she not been told of it a month after delivery.

On examination yesterday (five weeks after delivery), the coccyx was found to have re-united with the sacrum, though with a slight lateral deviation, which will be favorable rather than otherwise in the event of a subsequent pregnancy.

Should this occur, what method of delivery would be advisable? Nature led the way with a premature delivery at the seventh month. The result for the mother was better than in either of the subsequent confinements. The child was born alive and without injury. It lived twenty-six days; had it had the benefit of two weeks more of intra-uterine life, it might still have been living.

In the second confinement, at term, the head was so large that it refused to enter the pelvis. Version, of course, had to be performed, and the delivery of the after-coming head proved to be exceedingly difficult.

The child, an unusually bright boy of four, still bears the unequivocal signs of the difficulty of the extraction in two deep indentations in the skull, one in the centre of the occipital and the other near the posterior inferior angle of the right parietal bone. There is also a decided droop to the right shoulder due to the atrophy of the trapezius of that side, occasioned undoubtedly by prolonged pressure on the spinal accessory nerve at time of his birth, which Dr. E. H. Bradford, who kindly saw the case with me yesterday, says will probably disappear entirely under treatment.

Would version have been better than low forceps in the last confinement? It seems to me not, and for these reasons:

1. The risk to the mother from septic infection is undoubtedly greater when the cavity of the uterus is entered by the hand.
2. Injury to the soft parts from an after-coming head that hitches at the brim and that meets with obstacles to its progress throughout the whole canal (as is the case in a diminutive pelvis like the present), would be greater than from a head delivered by forceps after it had entered the cavity of the pelvis.
3. The risk to the child would be greater from the danger of prolonged pressure on the cord, owing to the difficulty of delivering the head after the extremities and trunk are born, a danger which is not so prolonged

and not so great where narrowing exists only at the inlet.

In a subsequent pregnancy I should, therefore, advise in the interest of both mother and child, induction of premature delivery at about the thirtieth week. If pregnancy should be allowed to go on to term, I should try to encourage the engaging of the head in the pelvis by binatural manipulation and not perform version unless the fetal heart or the mother's condition made it imperative.

## REPORT ON PROGRESS IN ORTHOPEDIC SURGERY.

BY E. H. BRADFORD, M.D., AND H. L. BURRELL, M.D.

### LATERAL DEVIATION OF THE SPINE.

F. R. FISHER<sup>1</sup> claims that a distinction should be made between deviations and curvatures of the spinal column, and states that much of the confusion regarding causation and the results of treatment is from lack of this important distinction.

Mr. Fisher figures three cases of so-called curvature of the spine; only one of these, he claims, is a curvature of the spine, the two others are deviations of the spinal column.

In a curvature of the spine he considers that there is rotation of the bodies of the vertebrae, whereas in a deviation of the spinal column there is no rotation.

He suggests the term, lateral bending, for a class of cases which occur in young girls who are overworked and underfed, the servant of the lower classes, girls educated at "cheap establishments for young ladies," those working in the second-rate drapery shops, and such like; it is also met with in those who have suffered from long illness of an exhausting nature, and in those affected with that defective condition of health commonly described as general debility.

Frequently accompanying this deformity is that mental condition which tends to exaggerate any bodily derangements. The hysterical complication generally appears at a late, and not at an early, stage of the affection, which must not be confounded with the so-called "hysterical spine."

### LATERAL CURVATURES.

Fischer<sup>2</sup> recommends in the treatment of scoliosis of a light grade, an attempt at correction by an elastic force. A band is placed around the shoulders like a figure of 8, bandages crossing behind and connected to an elastic strap which passes downward from the right side and forward over the breast and belly to a perineal band passing around the upper part of the left thigh.

In this way the right shoulder will be pulled forward and down, and the left hip up—as is desired in the correction of the ordinary form of lateral curvature. If the curvature is of the opposite type, the straps should be placed pulling from the left instead of from the right shoulder and to the right instead of the left hip, and if the curve is a single instead of a double curve, namely, if the right shoulder is raised and the right hip lowered, the strap should pass around the front of the body and the left side and be connected to a perineal band on the right thigh.

Walsham<sup>3</sup> generalizes from ninety-eight cases of

lateral curvature observed by him for two years. He thinks the following points are to be noted in recording cases: (1) The spinous process which deviates most from the median line. (2) The amount in distance of this variation. (3) Amount of the height of the elevated shoulder. (4) The height of the angle of the scapula. (5) Deviation of this from the vertical. (6) Height of the hips. (7) In what direction the thorax rotates. (8) The circumference of the thorax at the height of the vertebrae deviating from the vertical the most.

The cases were treated in a variety of ways and the following conclusions reached: (1) All lighter cases should be treated by gymnastics. (2) Appliances can be combined with gymnastic treatment. (3) Even in the severer cases gymnastics should be employed, and in event of failure corsets can be employed. (4) Corsets alone, however, never result in cure, rarely in improvement, and sometimes do not prevent an increase of deformity.

### OSTEOTOMY FOR ANCHYLOSIS AFTER HIP DISEASE.

The indications for this operation as given by Dr. Poore<sup>4</sup> are first, to correct all adduction of the limb, and second, to reduce or increase the flexion to an angle of 125° to 135° with the pelvis. This angle he has found by experience is the most useful one for a patient's limb to be fixed in.

He states that out of 132 cases of simple osteotomy through the neck of the femur and between and below the trochanters, twelve patients died, a percentage of 9.19. The fatal cases occurred in the early history of the operation, and of late years he does not know of a single fatal case, and he "would place an osteotomy, so far as danger goes, in the same class as a tenotomy."

### DISPLACED SEMILUNAR CARTILAGE.

Mr. Annandale<sup>5</sup> reports a case of this injury in a miner, when he made an incision along the upper and inner border of the tibia, parallel with the anterior margin of the internal semilunar cartilage, and after having secured a few superficial vessels, opened the joint. He then found that the semilunar cartilage was completely separated from its anterior attachments, and was displaced backwards about half an inch.

The cartilage was drawn forward into its natural position, and held there by three chromicised catgut stitches which passed through it and the fascia and periosteum covering the margin of the tibia.

The wound in the synovial membrane was closed by catgut stitches, a splint and a plaster-of-Paris bandage were applied, so as to keep the joint at rest.

Five months later the movements of the knee-joint were perfect.

### OSTEOTOMY.

Alfred Willett<sup>6</sup> gives the results of one hundred osteotomies. For genu valgum and varum, McEwen's or the supracondylar operation and Reeve's modification of Ogston's, or the intercondylar operation were the operations performed; the former by far the oftener, inasmuch as of eighty-two osteotomies upon forty-nine patients, no less than seventy-nine of these operations upon forty-seven patients were performed by McEwen's method, leaving only three oper-

<sup>2</sup> Centralblatt f. Chirurgie, No. 24, p. 417.

<sup>3</sup> St. Bartholomew's Hospital Report, 1881. Vol. xx, p. 195.

<sup>4</sup> United States Medical Journal, May 16, 1885.

<sup>5</sup> British Medical Journal, April 18, 1885, p. 773.

<sup>6</sup> Bartholomew's Hospital Reports, Vol. xx, 1884, p. 50-70.

ations upon two patients as having been submitted to Ogston's operations. Mr. Willett expresses the decided opinion that McEwen's operation fails to give an ideal result in the extreme cases of deformity.

In one case of genu valgum the deformity was so great that the leg formed nearly a right angle in its outward deflection; on this case he did a McEwen's transverse section of the femur, and found that on bringing the limb straight the lower fragment threatened to perforate the integument at the outer aspect of the thigh; he therefore placed the limb in as good a line as possible, lessening the deformity at least two-thirds and in this line allowed it to unite.

This case he believes would have been corrected by Reeve's modification of Ogston's or the intercondyloid method of osteotomy.

In a case of genu varum in which he attempted to divide the femur by McEwen's operations, he failed; he had carried on the operation in the customary way, until he had, as he thought, made a sufficient division of the femur with the chisel, which having been withdrawn, he attempted to fracture the remaining undivided layer on the posterior aspect of the bone, when, to his surprise, the lateral ligament gave way, and the leg at once fell into the desired position. He feels quite sure that he was not using more force than he ordinarily had employed. He has seen the lad recently and the limb is quite straight and useful. He has done eighty McEwen operations under full Listerian precautions. He is zealous in his praise of the safety and effectiveness of this operation. He has had one case where a very thin splinter of bone necrosed and came away; and another where a "considerable-sized piece" of the chisel broke off and was left in the bone—a matter apparently of no moment, for in this, as in another osteotomy, the after-progress gave no indication of anything unusual having occurred.

In one case of genu valgum which he attempted to forcibly straighten by Guérin's plan, shortly after Professor Guérin visited London and explained his method, he was obliged on the fifth day to abandon treatment, as his patient became so ill. Improvement in the patient's general condition quickly followed, but with scarcely any improvement in the position of the limb.

Six weeks later he did McEwen's operation and straightened the limb; the patient recovered without any fever or pain. All of his patients, with a very few exceptions, have perfect use of the limb, but all bear trace of the operation in an outward curve, more or less decided, in the lower fourths of their thighs.

Mr. Willett prefers the section of the neck of the femur by the chisel for the correction of hip-joint ankylosis.

#### BRUISEMENT FORCÉ—SUPPURATION.<sup>7</sup>

Oberst reports a case of ankylosis of several joints without evidence of active disease, ending in acute suppuration and death after forcible straightening. The patient was narcotized, and the ankle, left knee, left elbow and hand, were forcibly straightened. Fever followed and an abscess formed, leading to death by gradual exhaustion. At the autopsy, a fracture of the femur was discovered. In a second case, with old ankylosis of the knee, suppuration followed and amputation was necessary. Two other similar cases were also seen by the writer, and illustrated the point emphasized by the writer, that a slight amount of force will sometime be sufficient to wake up a long dormant

process, and that this method should be employed with great caution in cases of ankylosis after acute tuberculous affection, excision being probably less dangerous.

Szuman<sup>8</sup> mentions an equally serious result of forcible straightening of the knee of a child in apparent health, death ensuing from general tuberculosis following the brisement forcé. Little force was employed, but an elevation of the temperature followed, and rapid loss of weight, with cough. A diagnosis of general tuberculosis was made, which was confirmed at autopsy. A caseous focus was discovered at the head of the tibia.

#### TUBERCULOUS JOINT DISEASE AND GENERAL TUBERCULOSIS.

In a paper on the above subject,<sup>9</sup> Dr. F. S. Dennis summarizes as follows:

*First.* Scrofulous abscesses are dangerous, because in them bacilli tuberculosis may develop, and from these abscesses, as infective foci, general dissemination may proceed in the form of acute miliary tuberculosis.

*Second.* That tuberculous joint disease can produce general infection, or acute miliary tuberculosis.

*Third.* That traumatism may act as one of the many exciting causes to develop tuberculous joint disease, provided the conditions are favorable.

*Fourth.* That traumatism alone will not develop tuberculous joint disease, except when certain conditions are present.

#### TUBERCULOSIS OF THE TENDINOUS SHEATH.

Beger<sup>10</sup> distinguishes between primary and secondary form of this affection, which may be suppurative or not, circumscribed or diffuse, distributed over the whole sheath of the tendon. The prognosis is unfavorable. Of the four cases reported, amputation was necessary in two. In the other cases, extirpation of the tuberculous tissue led to a permanent healing. The conservative, non-operative treatment is of no value, and massage is particularly to be avoided.

#### SPINAL ARTHROPATHICS.

Hamilton<sup>11</sup> states that the joints most frequently affected in cerebral or spinal affections are the hip or knee, and usually only one joint is severely involved, though in rare instances, several joints may be attacked, and reports a case of this sort where the ankle, fingers, thumbs, shoulder, hand, and left knee. The local edema in joint affection of nervous origin begins suddenly, and diminishes as the destruction of the joint proceeds.

#### ON THE TREATMENT OF RICKETS BY PHOSPHORUS.

Meyer<sup>12</sup> reports his results in ninety-two cases of rickets treated by phosphorus (0.1 per cent. solution in cod liver oil or in emulsion).

In twenty-seven, were the digestive disturbances greatly improved. In twenty, the general condition was better to a marked degree. In six, the pain in the bones became diminished. Twelve of the cases still remained under treatment; thirty-eight either died of some intercurrent disorder, or passed out of observation. In forty-two, the result gained was quite satisfactory.

#### RESECTION OF THE VERTEBRAL BODIES.

Mayd<sup>13</sup> mentions the case of a man twenty-six

<sup>12</sup> Wiener Med. Presse, 1884, No. 42.

<sup>13</sup> Centralblatt f. Chir., No. 24, 1886, page 364.

years old, with vertebral disease following an injury with paraplegia, operated upon by him. After experimental dissections on animals, section of the spinal cord, and suture of the dura, he found that some of the animals survived and recovered from the procedure, and was induced to cut down upon the spinal column of his patient, and chiselled out the ninth, tenth, and eleventh vertebral arches, laying bare the spinal cord, which was found compressed by a piece of bone, which was chiselled out and removed. The patient recovered from the operation without difficulty, but the final result is not reported.

#### WRY NECK.

Volkmaun<sup>14</sup> advocates the open incision of the sterno-mastoid in severe cases of wry neck, followed by correction, by weight and pulley extension.

He has been able to examine microscopically portions of the contracted muscle, and from his observations inferred that there was no evidence of cicatricial tissue indicating a rupture of the muscle, which has by some been supposed to cause the deformity. The change discovered indicated rather an extensive previous inflammatory process of the muscle, the muscle in some cases having been completely transformed into fibrous tissue. No fatty degeneration of the muscle or atrophy was seen.

The advantage claimed for the direct incision of the sterno-mastoid is, that more thorough division of the deeper tissue is possible than by subcutaneous incision.

#### TUBERCULOSIS OF THE KNEE-JOINT.

Willmer<sup>15</sup> has collected the cases of knee-joint tuberculosis in the Göttingen Clinic in seven years, and generalized from the statistics. The treatment varied and is grouped as follows:

Plaster-of-Paris bandage preceded by extension and with or without incision of abscesses, curetting of sinuses, 35 per cent.

Partial resection, typical resection, amputation, 65 per cent.

The mortality in the cases not resected or amputated was 28 per cent., for the cases so operated, 32 per cent., and the mortality directly due to operation, 25 per cent.

The cases are grouped according to the age at which disease began—

49 per cent. were treated without resection or amputation, and 51 per cent. with, where the disease began before ten years of age; 23 per cent. without operative interference, 77 with, in cases where the disease began between ten and twenty years of age; and where the disease began after twenty, 74 per cent. were resected or amputated and 26 per cent. conservatively.

Classing the cases together, 40 per cent. made a good recovery; 20 per cent. made a poor recovery, or the result was uncertain; 30 per cent. died; 10 per cent. underwent amputation and removal. In regard to the shortening following treatment, the writer found that it was often not worse after conservative than after operative treatment (that is, excision). The contraction of the limb, which frequently takes place, appears to exercise an interference in the growth of the tibia, in a few cases a lengthening of the femur took place, but not usually. In regard to the time

necessary for cure in cases operated on and in those not operated on, accurate statistics are with difficulty obtained; the writer classifies his results as follows:

Of those not operated upon in three years 19 per cent. had recovered; 15 per cent. died; 66 were not well. In four years, 26 per cent. had recovered; 17 died; 57 not well. In five years, 24 per cent. had recovered; 21 had died; 55 not well. Taking all the cases (those operated and not operated), at the end of five years, 13 per cent. were well without operation; 37 were resected, with a mortality of 51 per cent.; 11 per cent. had been amputated, with a mortality of 60 per cent.; and 29 per cent. had remained not well.

#### ANCHYLOSIS OF THE JAW.—RESECTION.

Ranke<sup>16</sup> reports two successful cases of resection of the articulations of the jaw, and prefers König's incision along the lower border of the zygoma, to the vertical incision as avoiding the facial nerve. He also in certain cases prefers to leave the coronoid process, except when after removal of the articulating process, the opening of the jaw is interfered with. Kulenkampf also reports a similar case.

#### SPINA BIFIDA.

Langenbeck<sup>17</sup> reports a case of spina bifida lumbalis cured by one hundred iodine injections. The lower extremities remained, however, weaker than normal.

#### CLUB-FOOT.

In a paper on club-foot read to the Medical Society of Pennsylvania, Dr. De Forest Willard<sup>18</sup> reviews the literature of the subject and concludes that—

*First.* Even severe cases of talipes should not be considered incurable by moderate means, simply because they have relapsed after imperfect treatment by either surgeon or patient.

*Second.* In children under ten, even in extreme degrees of deformity, powerful manual force, with subcutaneous division of all the contracted tissues, will restore the foot without section of the bones, and should be first attempted. The degree of force required may be very great, but even if carried to rupture of tarsal ligaments, still leaves the injury subcutaneous. Should the hand fail, screw power is allowed.

*Third.* Fixation by gypsum splints in the straight position for a few weeks, followed by persistent manipulation, and the use of apparatus, will give a better walking foot than is attainable by resection.

*Fourth.* Tarsotomy is a valuable operation in cases which defy ordinary treatment, especially in adults, where the bones are irreducible and the ligaments strong. The operation should always be done antiseptically. The removal of a wedge-shaped piece is preferable to either excision of the astragalus or of the cuboid, the latter giving the poorest results.

#### CLUB FOOT.

Bessel-Hagen,<sup>19</sup> at the German Surgical Congress, read a paper upon the subject of club-foot. In the congenital form all portions of the foot are altered, and the chief change is not limited to the Chopart

<sup>14</sup> Centralblatt f. Chirurgie, No. 11, 1885, and No. 24, 1885.

<sup>14</sup> Centralblatt f. Chirurgie, April 1, 1885.

<sup>15</sup> Deutsche Zeitschrift f. Chirurgie, 1885, 21st Bd., 11 ff., 1.

articulation, but in the shape of the astragalus, especially in the neck of the astragalus.

Excision of the astragalus is to be preferred to a wedge-shaped tarsotomy if the soft parts are spared.

Wolff argued that operative interference was rarely if ever needed, and showed a case of congenital deformity in a patient nineteen years old corrected in nineteen days without tarsotomy.

Hirshberg also opposed the idea that excision was necessary.

#### OPERATIVE TREATMENT OF CLUB-FOOT.

Lorenz<sup>20</sup> has collected one hundred and forty-seven cases operated upon by excision of the tarsus. The methods of operation are classed as: 1. Osteotomy of the scaphoid and tibia. 2. Enuclation of the cuboid and astragalus with and without the removal of the end of the external malleolus. Removal by curette of spongy portion of the astragalus, leaving the cartilaginous surfaces untouched. Enuclation of the astragalus and removal of a vertical wedge of the anterior surface of the os calcis. 3. Enuclation of the astragalus cuboid and scaphoid, or of the astragalus cuboid and scaphoid, or of simply the scaphoid and cuboid. 4. Resection of the head of the astragalus, resection of a portion of bone on the outer side of the neck of the astragalus, resections of wedge-shaped portion of bone at the medio-tarsal articulation.

Of these but two will be likely, according to the reporter, to come into general use—one, removal of the astragalus chiefly in children, and the other, wedge-shaped resection of the tarsus in adults.

Enuclation of the astragalus is sufficient to enable the foot to be brought to a right angle, except in the rare cases where the calcaneus is united to the posterior surface of the tibia. Supination of the calcaneus can be corrected by removal of the astragalus, though in severe cases, the end of the fibula must be removed too. Supination of the whole foot is not directly corrected by removal of the astragalus, though the correction by appliances is made more easy, but in severe adult cases more bones have to be removed. Out of one hundred and sixty cases only two deaths are reported.

The writer believes that resection should be reserved only for cases of deformity remaining after a thorough operative attempt at forcible correction, a treatment which is sufficient in a large number of cases.

#### NON-DEFORMING CLUB-FOOT.

Dr. Shaffer<sup>21</sup> describes a condition of the tarsus, under the name of non-deforming club-foot.

"The state of affairs consists of a shortening of the inner half of the foot. The inner part of the foot contracts, antero-posteriorly principally, with the result of making the plantar arch noticeably hollow just posterior to the junction of the first metatarsal bone with its phalanx. The two inner metatarsal bones assume a position more nearly approximating a vertical line, and the whole of the inner half of the distal part of the foot is thrown out of normal relation to the rest of the foot and the body.

"The flexors of the ankle-joint proper are unable to perform the act of flexion; owing to the plantar resistance of the gastrocnemian resistance, or both.

"All those who have non-deforming club-foot, when

asked to flex the ankle put the toes in extreme extension in the effort to accomplish ankle-joint flexion.

"An awkward gait is apt to occur with gastrocnemian shortening and slight plantar trouble; while pain, 'gouty big-toe joints,' and disability are apt to occur when the plantar troubles are in excess."

If one places the patient in a recumbent, and asks him to flex the ankle keeping the knee straight, he cannot bring the "ball of the foot" into the normal plane of the heel, the former dropping from one-fourth to three-fourths of an inch below the latter.

The resistance cannot be overcome by voluntary muscular effort.

The two extensors come prominently into play, and, in some cases the phalanges assume a position nearly at right angles with the long axis of the first metatarsal bone.

If one tries manual pressure when the foot is in this position, one finds that the resistance formed by the plantar and posterior tibial muscles cannot be overcome, the resisting tissues are simply made more tense.

Dr. Shaffer gives five different causes: *First*, non-deforming club-foot seen after polio-myelitis anterior; *Second*, non-deforming club-foot which follows simple and uncomplicated malpositions, habit, etc. *Third*, non-deforming club-foot produced by traumatism, sprains, etc.; *Fourth*, non-deforming club-foot found after the infectious diseases of childhood, especially diphtheria and scarlet-fever; *Fifth*, the non-deforming club-foot due, as I believe, to some remote trophic disturbance, and seen quite frequently co-existing with true lateral curvature."

#### ASTRAGALOID OSTEOTOMY FOR FLAT-FOOT.

Mr. Stokes<sup>22</sup> renders the parts to be operated on aseptic, and makes an incision, an inch and a half in length along the inner edge of the foot, the centre of this incision being at the prominence formed by the head of the astragalus. At the centre of the incision, another is made at right angles to it, and a little behind the situation of Chopart's joint; and the two triangular flaps of skin are dissected back for about half an inch. A wedge-shaped piece of bone from the enlarged head and neck of the astragalus is then removed with an osteotome, and it is then found that by adducting and supinating the foot, the arch was perfectly restored. Mr. Stokes exhibited casts of the feet thus operated upon, and the results were very satisfactory.

#### CEREBRAL INFANTILE PARALYSIS.

Strumphell<sup>23</sup> states that this affection occurs frequently in the first year of life. It is an acute affection and occurs without apparent cause; it is ushered in with vomiting, fever, general convulsions and unconsciousness. These symptoms quickly disappear, and as a sequence one finds a complete paralysis of one-half of the body, which in its turn quickly disappears, in part. In some cases the paralysis is a monoplegia. There is never any degenerative atrophy of the muscles, though the growth of the limb is retarded. The affected limbs have an exaggerated tendon reflex, and there are frequently slight contractures.

Subsequently these patients suffer from epileptic attacks. Athetosis is a very frequent accompaniment.

The seat of the disease is supposed to be in the gray cortical substance in the motor region.

## Reports of Societies.

## THE NEW YORK ACADEMY OF MEDICINE.

STATED MEETING, November 5th, 1885.

## REPORTS OF SECTIONS.

Reports of meetings were made by the President of the Section of Obstetrics and Diseases of Women and Children, Dr. Alexander S. Hunter; the President of the Section of Practice of Medicine, Dr. Alfred L. Loomis, and the President of the Section of Neurology, Dr. Putzel.

Dr. D. B. ST. JOHN ROOSA read a

SKETCH OF THE LIFE OF JAMES LAWRENCE LITTLE, M.D., AND OF THE TWENTY-FIVE YEARS IN WHICH HE PRACTISED SURGERY IN NEW YORK.

Before receiving his diploma at the College of Physicians and Surgeons, in 1860, Dr. Little success-

fully passed a competitive examination and was appointed a junior assistant in Bellevue Hospital. The latter institution was just then coming into some importance as a school of surgery, and chiefly through the clinics of the late Dr. James R. Wood and his prizes for anatomical preparations offered for competition among the medical colleges; but it had much more importance as a school of medicine. As Dr. Little's tastes were especially inclined to surgery, when he graduated he resigned his position at Bellevue, and, after examination, he was appointed junior assistant in one of the surgical divisions of the New York Hospital. A resignation in one hospital to take a similar one in another was something unusual, and it was said at the time, that it caused a little unpleasant feeling among the staff at Bellevue, for Dr. Little was well known to some of them, and to Dr. Wood in particular, as a promising young man whom it was not well to lose. It was while he was in the New York Hospital that he devised his method of making and applying plaster-of-Paris splints, and Dr. Roosa in speaking of this, said: "It is not too much to say that chiefly, if not entirely, through Little's efforts plaster-of-Paris splints became a practical application. Until then, although much recommended, experience had shown that it was not well adapted for a surgical dressing. Little saw in plaster-of-Paris a material which, if properly used, would form that so much to be desired article, an immovable, and yet porous splint. . . . In using plaster-of-Paris as a splint, instead of a bandage, he utilized the material as was never before done; and although it is possible that it will never have a widespread use, just as Dr. Little employed it, he gave an impetus to the subject which was, perhaps, the origin of the famous plaster-of-Paris jackets. His paper upon the subject may be said to be classical."<sup>1</sup>

In regard to his skill as an operator, Dr. Roosa said: "Of Dr. Little's surgical achievements in detail, I am not competent to speak, nor is it necessary that I should do so. They are indelibly recorded in surgical literature—at least in part, for of late years Dr. Little was somewhat loth, from lack of time, perhaps, owing to his large and exacting public and private practice, to write as his friends might have wished. But I may say that he was the first American surgeon to puncture the bladder with the aspirator for the relief of retention of urine. He simultaneously ligated the subclavian and carotid arteries of the right side, for aneurism of the first part of the subclavian. The operation for stone by various methods he had performed seventy-seven times, with a fatal result in but two cases. In hare-lip and strangulated hernia, he also had a large and successful experience."

Dr. PAUL F. MENDE read a paper on

## ELECTRICITY AS A THERAPEUTIC AGENT IN GYNECOLOGY.

The routine use of electricity, he said, was certainly very uncommon in gynecological practice; and yet he himself, although by no means an expert in the use of this agent, had obtained some very excellent results with it during the last ten or twelve years, employing it for various affections with more or less benefit. The range of its applicability was quite large, and no special precautions were required in its use. Indeed, a patient suffering great pain when she came to the physician's

<sup>1</sup>Transactions of the American Medical Association, 1867.

office, was often entirely relieved, at least for the time, by the application. The faradic current was especially indicated in such troubles as malnutrition of the sexual organs, amenorrhoea, irregular menstruation, and subinvolution; and the galvanic in such as pelvic neuralgia, fibroids, and hyperplasia uteri.

There were certain cardinal points to be borne in mind, the enumeration of which was necessary before proceeding to speak in detail of the application of electricity in special forms of disease.

(1) The galvanic current was far more generally useful than the faradic, which, as a rule, has a stimulating effect, while the galvanic acts as a sedative.

(2) A mild, steady current would answer every purpose better than a powerful interrupted one. The faradic current, on the other hand, was useful in proportion to its strength.

(3) Whenever the constant current caused pain, it was doing harm.

(4) Personally, he could never decide which pole should preferably be placed within the body, provided care were taken that the current should not be too strong. There was, however, one marked exception. In cases where there was circumscribed pain, the positive pole was the one to be placed near the painful point. In using the faradic current, it was of no consequence which pole was employed internally. These remarks, however, he wished to be understood as applying exclusively to the use of electricity in connection with the pelvic organs, and not in the other parts of the body.

(5) He had always found it safe to begin with a mild current, and gradually increase its strength.

(6) When internal electrolyzation was to be employed, it was always best to introduce the internal pole before closing the connection, on account of the sensitiveness of the external parts.

(7) To be of any service, it was necessary that the treatment should be frequently repeated and should be continued for a long time. As a rule, it was quite useless to make applications less frequently than twice a week, and the course of treatment should last from three to six months.

(8) The results of faradization in chronic affections were less favorable than those of galvanism; but, while relief from pain and an amelioration of the general condition was very often obtained by this means, a complete cure was usually not to be looked for.

He then called attention to a number of pathological conditions in which treatment of electricity was advisable. In deficient development of the uterus and ovaries, if the organs were merely rudimentary, nothing was to be hoped for from any kind of treatment; but if the uterus were of the normal shape, though small, and any tendency to a molimen were evinced, there was a fair prospect of good results from the persevering use of the faradic current, aided by spongers and appropriate constitutional measures. The application was to be made every other day, and for a week before the expected period, the current was to be employed in increased strength and for a long time at each sitting. The galvanic stem sometimes used, he thought was of service simply as a foreign body in the uterine cavity. Chlorosis and amenorrhoea (including depressed and irregular menstruation), were often relieved by electricity, combined with other local, as well as constitutional treatment. In married women, electricity was called for in amenorrhoea oftener than in the un-

married, and it was frequently of great service when the circulation was sluggish, and the energies of the system were directed rather to the formation of adipose tissue than towards the pelvic organs. The same was true as regards some unmarried women, and it was not seldom found that when the flesh had been reduced, the amenorrhoea disappeared. No reliance, Dr. Mundé thought, was to be placed on emmenagogues of the books. Better results can be obtained, however, with permanganate of potassium, though no other agent was to be compared with electricity in value.

In cases of subinvolution and menorrhagia, when of recent date, the faradic current was indicated. In others, the constant current was of most service, though it was not advisable to introduce the electrode within the uterus. In hyperplasia uteri, galvanization was often of very great benefit, both for the relief of reflex neurosis which it afforded, and for its utility in the removal of abnormal tissue. In this condition, the long and frequent application of the current was called for, and intra-uterine medication was to be employed in addition. In chronic oöphoritis and pachysalpingitis, which were extremely painful and annoying conditions, Dr. Mundé thought that the condition of the ovaries was analogous to that of the tonsils after repeated attacks of inflammation, in which there was no cure but removal. The same was true with regard to chronic catarrh of the Fallopian tubes, and on account of the hyperplasia of the walls of the latter he had ventured to apply the term pachy-meningitis. In connection with this trouble, there was also periöphoritis, and the sufferings incident to the whole condition usually rendered life a burden. The only cure was salpingo-oöphorectomy, and in Tait's hands, it had proved an operation comparatively free from risk; but no other operator had met with the same extraordinary success. In addition to the danger under ordinary circumstances, there was a grave objection to subjecting young married women to an operation which deprives them of all hope of offspring, especially as there was a possibility of pregnancy occurring in women in this condition. The radical operation should be deferred, therefore, until all other measures had failed to give relief, except in those instances where imminent danger to the patient called for its prompt performance.

He had seen very great benefit derived from palliative treatment, and the use of electricity was often of great service in supplementing other local measures. It relieved pain for hours, and even days, at a time, and by its anæsthetic influence rendered the diffuse thickening in the broad ligaments less tender to the touch. While it was true that the relief was only temporary, there was in many cases a chance that pregnancy might occur, and in others that the menopause would soon intervene.

In chronic pelvic cellulitis, peritonitis and lymphangitis, the ordinary treatment afforded very little relief, and there was nothing by any means equal to a mild constant current, he said, for this purpose. In acute and subacute exudations, however, electricity was to be avoided, on account of the danger of setting up new trouble. In obstructive and neuralgic dysmenorrhoea when other means had failed to give relief, galvanic electricity would often be found of very great service; the negative pole being carried up into the uterus, and not more than ten cells being used. In the treatment of uterine fibroids, Dr. Mundé thought electricity had a future. Apostole, of Paris, had reported quite

remarkable results at the International Medical Congress at Copenhagen; and Everett, of Ohio, had also met with success in this field. The methods at present in use are, at all events, safe; which was more than could be said of the electro-puncture of Kimball and Cutler, which in more than one instance had resulted fatally. He then referred to a case which he had seen in consultation with Dr. Freeman, of Brooklyn, who afterwards produced a cure by electrolysis, and reported it in a paper read before the Kings County Medical Society. It was one of subperitoneal fibroid, and the galvanic current was applied by means of an insulated steel needle thrust into the tumor.

Dr. Mundé gave the following

#### CONCLUSIONS.

(1) Electricity is a valuable agent in gynecology, and one which deserves to be much more frequently resorted to than is now the case.

(2) Its application in gynecological practice does not require special skill in the use of electricity.

(3) The remedy, if properly used, cannot do harm.

(4) It is of especial service in chronic conditions, and no pain is caused if the galvanic current is employed.

(5) The faradic current is indicated in deficient development and want of tone in the pelvic organs.

(6) The galvanic current is to be used to promote absorption of adventitious products and allay pain.

(7) This method of treatment requires much perseverance.

(8) It is contra-indicated in acute and sub-acute inflammatory conditions.

(9) The pathological conditions in which electricity proves useful are those in which other treatment often fails, or cannot be borne by the patient.

(10) In organic disease a permanent cure or a restoration of the diseased organs to perfect health cannot be expected; but very marked relief, and that without danger, may often be afforded by means of electricity.

DR. FREEMAN, of Brooklyn, in opening the discussion of the paper, said that he coincided with Dr. Mundé in almost every particular. In his own practice he had now almost entirely given up the use of the faradic current for the galvanic, except for the purpose of exciting muscular contraction, and this could also be accomplished by the interrupted galvanic. There was another form of electricity, which was not mentioned in the paper, namely, the static; and during the last four years he had employed this forty times as often as either of the others. It possessed a great advantage in that it could be used so easily and so pleasantly to the patient, and the removal of the clothing was not required. One of the most useful purposes which electricity served was the relief of pain, and on this account it had proved a great boon, as it enabled us to a large extent to avoid the use of opiates. Under the application of the static current pain often disappeared as if by magic, and the patient felt a pleasant exhilaration not unlike that caused by champagne, though not attended with any disagreeable consequences. He then described in detail the case referred to by Dr. Mundé in the paper, and also two others which had been cured of uterine fibroids by means of electrolysis. In none of them was any rise of temperature caused by this treatment.

Dr. A. D. ROCKWELL said that he had been very

much pleased with the paper, as he had held for a long time that electricity should hold a higher position in gynecology, as well as in general practice than it has hitherto done. He had seen it employed in various conditions to which Dr. Mundé had referred, and could testify to the correctness of his statements. In subinvolution, however, he should expect that the galvanic current would be of more service than the faradic. The thing that interested him most, because it was a new application of the remedy, was the use of galvanism in pelvic cellulitis.

Dr. GARRIGUES said that he had used electricity in gynecological practice to some extent for about thirteen years, and the chief cause why he had not used it more was because it took up too much time. Another reason was, that he had found that he could get as good results with other remedies which did not occupy so much time. The condition in which he had most frequently employed it was amenorrhea, and in this it had not always answered the desired purpose. The simple introduction of the sound had proved almost as useful here as any other method of treatment. Internal remedies, especially iron and permanganate of potassium had also given satisfaction in his hands. One difficulty which he had met with in the use of galvanism was that, even with a weak current, the electrode introduced within the vagina produced an escharotic effect.

Dr. BIRDSEALL said that the literature of the subject was rather mystifying and unsatisfactory, and one great difficulty was to find out what the observers who reported cases had really used. One point very hard to get at was the strength of the current applied in any given instance. The number of cells reported as used, while (provided the battery was in good working order), it might act as a guide to those who are familiar with exactly the same apparatus, conveyed no idea of the power employed to others reading the accounts.

The only real test was the galvanometer, and notwithstanding the difficulties in the way of using it, he trusted that it would be generally adopted at no distant date. As to the matter of subinvolution, he thought that galvanism was much more serviceable than the faradic; which was indicated in all cases where he wished to excite muscular contraction or cutaneous irritation. The most important, perhaps, of the conclusions enumerated by the author of the paper was the one in which the caution was given about using electricity in acute and subacute cases.

DRS. McLENN and BURKE also spoke, and the discussion was closed by Dr. Mundé. In speaking of subinvolution the latter said that he recommended the faradic current only in the early stages with menorrhagia. Afterwards the condition was very much the same as in hyperplasia of the uterus, and the galvanic current was chiefly to be used. He had never had any experience with static electricity, and should be glad to give it a trial.

The president stated that Dr. Jamesay, who had been appointed to deliver the

#### ANNIVERSARY DISCOURSE.

was unable to do so on account of ill health, and that Dr. Henry D. Noyes, although the notice was a very short one, had kindly consented to take his place. The address would be given at the next stated meeting of the Academy, November 19.

## NEW YORK NEUROLOGICAL SOCIETY.

STATED Meeting, October 6, 1885.

The president, W. R. BIRDSALL, M.D., in the chair.  
Dr. E. C. SEGUIN read a paper entitled

A CONTRIBUTION TO THE PATHOLOGY OF HEMIANOPSIA OF CENTRAL ORIGIN.—CASE WITH SPECIMEN.

The writer first gave a brief synopsis of views, anatomical and pathological, of hemianopsia of basal or peripheral origin; recognizing the following types: 1. Horizontal H., superior or inferior, usually due to lesions within the eye, and hence of less interest to the neurologist. 2. Vertical H., always caused by a lesion of the basal visual apparatus or by disease in a certain limited part of the cerebrum. Varieties of 2: (a) Temporal hemianopsia, in which the temporal half of both visual fields is dark. (b) Nasal H., in which the nasal half of both visual fields is obscured. (c) Lateral H. This is often designated homonymous H. In this variety the nasal half of one visual field and the temporal half of the other are dark, so that with one or both eyes open the patient sees the same half of any object placed in front of him. This variety is the one which results from a truly central lesion, and forms the object of study in the paper.

Varieties *a* and *b* are caused by lesions variously placed in or around the chiasm of the optic nerves.

The author proceeded to analyze the recorded observations of hemianopsia due to cerebral lesion, forty-two in number, including the author's own case. Of these, thirty-seven were medical, and accompanied by aopsies; five surgical, followed by survival of the patient. These relatively numerous observations were classified as follows:

(a) Cases of lateral hemianopsia, indefinite or irrelevant, and useless for localization study, four in number: observed by Charcot, Pitres, Linnell, Wiethe and Petrina. (b) Cases of lateral H., from lesions of parts of brain not directly related to the optic apparatus; (three cases) by Hirschberg, Huguenin (observers of 1876) and Pfleger. (c) Cases of lateral H., from lesions involving chiefly the thalamus opticus or corpus geniculatum laterale: six in number; by Jackson and Gowers, Pooley, Dreschfeld (two cases) and Rosenbach. (d) Cases of lateral H., from lesions chiefly or exclusively involving the white substance of the occipital lobe (eleven cases), by Levick, Hirsch, Baumgarten, Dmitrowsky and Lebedev, Westphal (1881), Senators, Stenger (case seven), Wernicke, and Hahn, Jany, Richter, and Schmalz. (e) Cases of lateral H., of external or traumatic origin: five cases; by Keen and Thomson (re-examined by Dr. Seguin), Hughes, Schmidt, R. Kimpfer, Heuse and Nieden. (f) Cases of lateral H., due to lesions involving the cortex of the brain and subjacent white substance; thirteen cases; by Westphal (1882), Stenger (case eight), Förster and Wernicke, Jastrowitz (two cases), Curschmann, Nothnagel, Marchand, Chailion, Haab, Huguenin (1882), Féré and the author's case.

This last category being by far the most important for the study of the localization of the visual centre in man, Dr. Seguin gave full abstracts of all these cases. The lesions in all were so placed as to cumulate toward the mesal aspect of the occipital lobe. This result was shown by means of a shaded chart, consisting of a diagram of the mesal and lateral views of the brain,

upon which the lesions of the thirteen cases were reproduced with one layer of india ink. The result was striking, visible in the greatest blackness of an area upon the mesal aspect of the cerebrum, including the lower part of the cuneus and the fifth temporal gyrus (Ecker). To this locality also was limited the lesion found in the following cases; Haab's, Huguenin's Féré's, and Seguin's. These were single lesions, and only hemianopsia with no paralysis or anesthesia had been observed during the patient's life.

Dr. Seguin's own case was as follows: a man aged forty-six, affected with malignant endocarditis (mitral vegetations) which proved fatal in sixteen months from first observation in January, 1884, through repeated visceral embolisms. This case also exhibited for many weeks a typical intermittent form of fever, closely imitating malarial intermittence.

About December 5, 1884, Mr. D. suddenly complained of "blindness of the left eye," and slight numbness through the whole left side of the body. He strongly insisted then, and frequently thereafter, that his left eye was alone affected, because he could not see to his left. Examination showed well-defined left lateral hemianopsia, the vertical line passing a little to the left of the point of fixation. In a short time the numbness passed away, but the hemianopsia persisted until death. For many months before death, Mr. D. was able to read and write easily and attend to outside business, in spite of the hemianopsia.

The lesion found at the autopsy was a large old patch of yellow softening, involving the greater part of the right cuneus (almost reaching the apex of the occipital lobe), and the fifth and fourth temporal gyri, extending also frontal into the gyrus hippocampi. This lesion was found to be due to blockade of the occipital artery branch of the posterior cerebral. The white matter was involved to a depth of several millimeters.

No sections were made in the fresh state of the specimen, in order to prepare it for more careful examination when hardened. Unfortunately this process was unsuccessful in part, and only the occipital end of the brain became hard. The absence of decided motor and sensory symptoms during life, however, makes it quite certain that there was no other gross lesions in the brain.

From these four cases, supported by the cumulative evidence of all the others, Dr. Seguin considered it as well proven that the visual centre (receiving impressions from one corresponding half of each retina), in man, is in the cuneus and adjacent gray matter below it. A destruction of this part of the hemisphere inevitably produces hemianopsia of the field on the opposite side of the body.

As regards those few cases in which the lesion causing lateral hemianopsia was situated upon the lateral aspect of the hemisphere, in the inferior parietal lobule and the gyrus angularis, Dr. Seguin called attention to the fact that the optic fasciculus of Gratiolet and Wernicke on its way from the primary optic centres, lateral of the posterior horn of the lateral ventricle, to the cuneus, passes close under these gyri, and a lesion which penetrates at all beneath the gray matter of their cortex must intercept, by pressure or by destruction, the optic fibres. These are lesions intercepting communication between the eyes and the visual centre, while lesions of the mesal aspect of the occipital lobe destroy the centre itself.

## DISCUSSION.

DR. T. R. POOLEY. — Mr. President: without knowing at all the direction which Dr. Seguin's paper would take, I hastily looked over my records this evening and briefly abstracted five cases of hemianopsia of which I have notes. One of these cases has been referred to by Dr. Seguin in his paper. I feel quite incompetent to discuss the physiological and theoretical question as to the location of the lesion, and the importance of different symptoms in helping us to exactly locate the lesion in the brain. Nor will I at this late hour refer to all the cases of which I had intended to relate somewhat in detail the clinical histories. I shall content myself with speaking only of one case which has recently come under my observation and which is now under treatment. It is a case which I saw a week ago, that of a gentleman, aged thirty-five years, who came under my care in 1879 for comparative blindness of his left eye, which I found to be due to circumscribed choroidal exudation situated near the macula lutea. In my former experience with such cases I always believed them to be due to syphilitic infection, and careful inquiry into the history of this case showed it also to be due to this poison. The patient remained for a time under treatment for this inflammatory exudation, from which he recovered with a scotoma, and enjoyed comparatively good health and freedom from all further syphilitic manifestations until a week ago, when he consulted me again. On this occasion he was driving with his wife in the country, when he suddenly became completely blind. This blindness lasted only a few moments. Upon recovering, he ascertained that there was dimness of vision upon the left side, which continued when he came to see me. Examination showed left homonymous hemianopsia. The blind area extending almost to the point of fixation in each eye. Examination of acuteness of vision showed in the left eye — and this is interesting because of the previous condition of that eye — twenty-two hundredths; the right eye twenty-twentieths, or perfect. The optic discs were quite normal, the bloodvessels were of full size, there was no indication of atrophy of the optic nerve by neuritis. The interesting and remarkable fact in this case is the improvement which took place within a week from the commencement of treatment. On account of the previous history of the case the patient was placed upon large doses of iodide of potassium. Former experience with the use of the drug, however, led me at first to give comparatively small doses, only fifteen grains. But I found that he tolerated large doses much better than small ones, and I immediately began pushing the remedy so that I gave him one drachm three times a day on the third day. Already, upon the first day after treatment had been begun, the visual fields had increased in extent, and this increase has steadily continued until the present date. Unfortunately I have not had opportunity to make measurements with the perimeter, the patient being treated at his home, but I may estimate that the field of vision has extended from near the point of fixation to one-third the normal limits, the increase being apparently symmetrical. I should like very much to have Dr. Seguin's opinion as to whether in a case of this kind, in which there has been such marked improvement within a week, we may hope for permanent benefit.

DR. M. A. STARR. — At this late hour I will not

detain the Society but a moment. I think the list Dr. Seguin has presented is a complete one, with perhaps a single exception, that of a case reported by Demange in the *Révue de Médecine* for May, 1883. That case is referred to by Dr. Gowers in his last work on diseases of the brain, in a way to lead one to suppose that it supported the assertion of Ferrier, that the angular gyrus is the centre for vision. I found, however, on looking up the case, that the lesion was one which coincided very largely with that of the first case of Westphal, and is very well represented by the diagram shown by Dr. Seguin of that case. It was a very large lesion, involving both parietal lobules and the occipital lobe. Gowers refers to that case as proving that a lesion upon one side of the brain may produce blindness of the opposite eye, and says it supports Ferrier's assertion of amblyopia being due to lesion of one angular gyrus. In the original report, however, it is only stated that the patient could not see well with the left eye, and it does not state that there had been any careful measurement of the field of vision. Therefore, in all probability the patient had hemianopsia, and as in a number of cases reported by Dr. Seguin, and in a number which I collected, lack of careful observation on the part of the examining physician failed to elicit the symptom which was undoubtedly present. The necessity for careful examination in all of these cases has been dwelt upon by Dr. Seguin, and I think it ought to be emphasized, because it is evident from the history of these cases that a patient with hemianopsia does not notice the exact field of vision, but only notices that he is blind in one eye, and refers it to the eye whose field of vision is most largely implicated. The necessity for such an examination is shown in the fact that Dr. Seguin has been able to collect eight cases in addition to those which I had collected, that is to say, eight new cases have occurred since January, 1884. This great increase in the number of cases of hemianopsia is only apparent, few cases having been recorded previously, because of imperfect examinations of the visual field.

I would not anticipate Dr. Seguin in answering the question asked by Dr. Pooley, but I have in my hand a case published by Baer in Volkmann's "Sammlung Klinischer Vorträge," which is almost identical with that related by Dr. Pooley this evening; a case of hemianopsia coming on suddenly in a syphilitic individual. A series of diagrams are given, showing the progressive improvement of the patient and final complete recovery.

My attention was first called to the subject three years ago, by seeing a case of hemianopsia in Charcot's wards, and in his lecture on that case Charcot virtually retraced his own diagram and adopted one like that shown by Dr. Seguin. So that I think we should cease to copy the old diagram made by Charcot, and it has been abandoned in France and Germany.

The absolute necessity for such a collection of cases as Dr. Seguin has made for settling any disputed question of localization is perfectly evident to you all. It is the only way in which this question of localization can be really determined. To make conclusions from physiological experiments I think is no longer warranted. We must go to carefully making autopsies.

It may be interesting to know that in October, 1858, the Pathological Society of Philadelphia dis-

cussed the subject of abscess of the brain, and at that meeting Dr. Weir Mitchell presented a case with the records in which a large abscess at the posterior part of the brain, involving both occipital lobes, was attended with blindness, and the blindness seemed to be the chief local symptom—as we should say now—of the disease. The Pathological Society were at a loss to explain the occurrence of blindness with this lesion in the occipital lobes.

I think it is encouraging to the general cause of clinical diagnosis that now, after the lapse of these years, we are able to explain perfectly that case which then so puzzled the Pathological Society of Philadelphia.

Dr. Seguin closed the discussion, and apologized for having detained the Society with so long a paper. With reference to Dr. Pooley's question, he would have declined to answer it for want of experience. He had never seen a case of hemianopsia which was not embolic or possibly due to a tumor, and in which there was no indication for treatment.

### Recent Literature.

*A System of Practical Medicine* by American Authors. Edited by WILLIAM PEPPER, M.D., LL.D., and LOUIS STARR, M.D. Volume II. General Diseases (continued), and Diseases of the Digestive System. Volume III. Diseases of the Respiratory, Circulatory, and Hematopoietic Systems. Philadelphia: Lea Brothers & Co. 1885.

The second and third volumes of this System of Practical Medicine, edited by Professors William Pepper and Louis Starr, and published by Lea Brothers & Co., of Philadelphia, are quite up to the high standard of the first volume. When we state that Volume II consists of over thirteen hundred royal octavo pages contributed by twenty-two different writers on thirty-eight separate subjects, with an index; and that Volume III consists of more than one thousand such pages contributed by twenty-seven different writers on forty-five separate subjects, with an index, we have given some indication of the scope of the work and said enough to show the impossibility of a serious review in the columns of a weekly journal.

Volume II begins with an article on Rheumatism, by Dr. R. P. Howard, the efficient Dean of McGill University, Montreal. In about ninety pages he discusses this interesting and important subject in a manner which shows his acquaintance with its practical problems as well as with its recent literature, and leaves little to be desired.

We notice the statement that in Montreal, the largest number of cases of acute rheumatism admitted to the General Hospital occurred in the spring months, from March to June inclusive, as in accordance with the experience of other cities in the northern United States.

An article on Gout, of twenty-six pages, by Dr. W. H. Draper, of New York, follows. The difference in length of the two articles fairly indicating the difference in importance and frequency of the two diseases on this continent. Rachitis is dealt with by Dr. A. Jacob, of New York, and Scurvy by Dr. P. S. Wales, ex-magnum-general of the U. S. Navy. Dr. James Tyson, of Philadelphia, contributes a careful article on Dia-

betes Mellitus. An article by Dr. J. William White, of Philadelphia, on Hereditary Syphilis, presents this extremely important subject in the space of seventy odd pages in an altogether admirable manner. Any one wishing to consult the latest dicta on heredity in syphilis and the provisions requisite to guard against the propagation of this disease by inheritance will find them nowhere more logically worked out or more clearly stated. Dr. J. Edmonson Atkinson writes on Purpura, and Dr. John S. Lynch on Scrofula. This completes the list of subjects under the head of General Diseases.

The Diseases of the Digestive System are done justice to by a number of different writers. The large part of the writing on these diseases, however, comes from the pens of Dr. J. Solis Cohen, of Philadelphia, who treats of diseases of the Mouth and Tongue, of the Tonsils, of the Pharynx, and of the Oesophagus; of Dr. W. H. Welch, of the Johns Hopkins University, who deals with Simple Ulcer, Cancer, Dilatation of the Stomach, Hemorrhage from the Stomach, and Minor organic Affections of the Stomach; W. W. Johnstone, of Washington, who elucidates Intestinal Indigestion, Constipation, Enteralgia, Acute and Chronic Intestinal Catarrh, and Cholera Morbus; and James T. Whittaker, of Cincinnati, who presents Dysentery, Typhilitis, Perityphilitis and Paratyphilitis, Intestinal Ulcer, and Hemorrhage of the Bowels.

Of single articles, that on Intestinal Affections of Children in Hot Weather, is by Dr. Lewis Smith, of New York; on Peritonitis, by Dr. Alonzo Clark; on Diseases of the Abdominal Glands, by Dr. S. C. Busey, of Washington; of the Liver, a long article of nearly fifty pages, by Dr. Roberts Bartholow; of the Pancreas, by Dr. Louis Starr, the assistant editor of this System.

Dr. Joseph Leidy, than whom there is no higher authority, contributes an article on Intestinal Worms. Dr. Hunter McGuire, of Richmond, occupies fifty pages with Intestinal Obstruction; and Diseases of the Rectum and Anus are considered by Drs. T. G. Morton and H. M. Wetherill, jointly.

Volume III, devoted to the diseases of the Respiratory, Circulatory and Hematopoietic Systems, discusses some of the most usual and serious affections which the medical practitioner is called upon to contend with. Some of these subjects are treated by writers whose names appear in the previous volume, to others new names are attached; all the writers are competent and carefully chosen, while some are among the most distinguished in the profession. Croupous Pneumonia has been confided to Dr. Alfred L. Loomis of New York, whilst the Editor has taken Catarrhal Pneumonia himself. Dr. Loomis also discusses Endocarditis and Chronic Valvular Diseases under the diseases of the circulatory system. Dr. Austin Flint writes on Pulmonary Phthisis and Neuroses of the Heart; Dr. J. M. DaCosta on Diseases of the Pericardium.

We notice with surprise that Dr. N. S. Davis, in his article on Bronchitis, under the head of Rheumatic Bronchitis makes no mention of Dr. F. H. Buckler, of Baltimore, an omission atoned for by Dr. Frank Donaldson in speaking of rheumatic pleurisy in his excellent article on Diseases of the Pleura.

Among the younger contributors, whose names are guarantees of good work and of an eager acquaintance with recent advances, are Drs. William Osler, J. B. Roberts, and Morris Longstrech, of Philadelphia, G.

M. Garland and E. G. Cutler, of Boston, Beverly Robinson and Heermance Smith, of New York. Dr. Osler's article, covering nearly seventy pages, on Diseases of the Blood and Blood-Glandular System is a very excellent one.

Drs. S. C. Chew, of Baltimore, Edward T. Bruen, of Philadelphia, and William Carson, of Cincinnati, each deal with several topics under Diseases of the Respiratory System; Laryngoscopy and Rhinoscopy, and Diseases of the Nasal Passages, of the Larynx and Trachea are handled by Drs. Carl Seiler, Harrison Allen, Hosmer Johnson, A. Jacob, Louis Elsberg, and George M. Leferts. Dr. W. N. Geldings, of South Carolina, who spends his summers at Bethlehem, N. H., writes about Asthma and Hay Asthma.

Recognizing, as we have said, the impossibility of giving a careful analysis of each of the numerous papers on divers subjects in these two large volumes in any space at our command, we have thought the interest of our readers was best subserved by a sketch of their general scope and a knowledge of who the contributors are. Such a work is only purchased after careful reflection and with a view to its general excellence. Exceptionally good as some of the articles in these volumes certainly are, the general standard is nevertheless very high, and we do not hesitate to say that if this standard is reached in the volumes to come, this will be easily the best System of Medicine yet published in the English language.

*Tracheotomy in Laryngeal Diphtheria.* By ROBERT WILLIAM PARKER. Second Edition. London, 1885.

This is a very practical treatise upon the subject of the local treatment of diphtheria of the larynx and trachea. The author advises vigorous antiseptic measures, as he believes the disease to be at first local, and to finally become general by the absorption of the septic products from the local lesions.

Tracheotomy is simply a mechanical method of prolonging life while the local treatment may have time to overcome the disease. Mr. Parker considers at some length the injurious effects which an ill-fitting tube may work on the walls of the trachea, and with the object of avoiding this, he recommends the use of a tube which, instead of being bent into the segment of a circle, is shaped to an obtuse angle of which the lower limb shall coincide with the direction of the trachea.

It is difficult to understand how, with this bend in the tube, the inner tube can be taken out to cleanse it. The book is well printed, on good paper, and the cuts of instruments and apparatus add to its value.

*Post-Mortem Examinations, with Especial Reference to Medico-Legal Practice.* By PROF. R. VICHOW. Translated by T. P. SMITH, M.D. Philadelphia: P. Blakiston, Son & Co. 1885. 138 pp.

This excellent little book, which is really the foundation of the modern method of performing autopsies, is now translated into English. The general principles and the various steps of the process have already become so well known and incorporated in the text-books, that it is not, perhaps, so much needed as some years ago. But its rank as the standard authority will always give it value, and it should certainly be the *code mecum* of every medico-legal examiner.

## Medical and Surgical Journal.

THURSDAY, NOVEMBER 19, 1885.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly, by CUPPLES, UPHAM & CO., Boston. Price, 15 cents a number; \$5.00 a year, including postage, to subscribers in the United States and Canada. Foreign subscribers are charged the postage in addition.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.*

CUPPLES, UPHAM & COMPANY,

283 WASHINGTON STREET, BOSTON, MASS.

### PASTEUR AND HYDROPHOBIA.

It is now four or five years since Pasteur's name began to be associated with hydrophobia. At that time before his enthusiasms and those of his fellow-workers in his laboratory had been chilled by the attacks of Koch, he and they allowed themselves to believe that they had discovered in the saliva of rabid dogs and of human beings suffering from the disease the specific micro-organism of hydrophobia. This discovery was prematurely brought forth and did not long stand the test of more careful and thorough research. It was soon shown beyond question that a micro-organism identical in appearance was not unusually present in the saliva of children afflicted with other diseases, and even in the saliva of the healthy.

The announcement of this pseudo-discovery, together with Koch's demonstration that Pasteur's methods of obtaining "pure cultures" of various microbes were very liable to errors, and the unsuccessful issue of the French Cholera Commission in Egypt which was under Pasteur's direction, had no little influence in diminishing the prestige which he had hitherto enjoyed as a micro-biologist. At the Copenhagen meeting of the International Medical Congress, Pasteur announced not that he had rediscovered the microbe of hydrophobia, but that he had discovered a cure for the disease by inoculation. In previous more or less successful efforts to secure protection against diseases by inoculation, as with anthrax, chicken cholera, etc., the specific micro-organism had been eliminated first and an attenuated virus then sought by successive attenuated cultures. From what could be learned of this latest discovery it seemed that the preliminary step had been dispensed with, and the grand result obtained at one stride. Further reports confirm this impression.

Of late the daily press has contained frequent accounts of the success of Pasteur's operations. Previous experience of this sort of enterprise among our esteemed daily contemporaries, fortified by the collapse of the cholera inoculations of Ferran, has hitherto induced us to await further confirmatory evidence.

The latest information we have, comes in the form

of cable reports to the New York *Herald* of a meeting of the French Academy of Sciences in Paris, at which Pasteur explained his process of inoculation and exhibited a lad who had been brought to him from Alsace sixty hours after having been bitten fourteen times by a dog, proved by an autopsy to have been rabid! A celebrated surgeon and a celebrated veterinarian pronounced the boy doomed to a painful death! During thirteen days Pasteur inoculated the boy frequently with virus of constantly increasing strength. When shown to the Academy the boy was free from hydrophobia, and one hundred days had elapsed since he was bitten by the dog. Another boy, bitten a fortnight before, had been a week under treatment, and his cure was confidently anticipated. These are the simple facts, as reported, of Pasteur's present position as a discoverer of a cure for hydrophobia. The report may do him too much or too little justice, and should be received as medical gossip rather than as scientific facts. The same enterprising daily lately reported the death of a well-known actor as imminent, on account of the appearance of "Steynstokes" (Cheyne-Stokes) respiration, a peculiar breathing, the reporter went on to explain, named after the discoverer Mr. Steynstokes. The official report of the Academy of Sciences will soon be at hand, and Pasteur's exact claims may then be better judged.

The method pursued seems to consist in inoculating a rabbit with bits of the spinal cord of a rabid dog, and then inoculating a succession of rabbits from each other. With each successive inoculation the virus is said to increase in potency! The period of incubation of the disease in the case of the sixty-first rabbit in a series, being reported as only seven days. Portions of spinal cord are suspended in bottles containing dried air for various periods of time, the oldest being the least active. A protective inoculation is sought by inoculating in a descending scale with bits of spinal cord of different disease-generations and of different ages, in other words, of increasing potencies. Pasteur is reported as claiming that the protection is operative after a bite from a rabid animal, but how long after, and whether after symptoms of hydrophobia have been developed, we have not learned. Pasteur is said to recommend that the government keep constantly on hand a supply of rabid spinal cords of different degrees of potency.

It would be idle at present to criticize these reported methods and claims. We should have preferred to await further details, and have referred to them mainly that our readers may not accuse us of neglecting the events of the day. A few observations, however, are in place.

The most careful microscopical examinations hitherto made by the most competent observers have shown that the changes attendant upon hydrophobia were to be found in the medulla, and but little or not at all in the cord. There is no pretence even, apparently, at this time, that the active principle of the hydrophobic poison has been discovered, and in comparison

with previous methods of inoculating with attenuated virus this seems to be a very crude and gross one. If the Alsacian lad is unaffected by inoculations which produce rabies in a few days in dogs and rabbits, Pasteur's alleged announcements are certainly worthy of very serious examination and consideration, but otherwise they do not inspire confidence. The period of inoculation of hydrophobia is a very variable one; it may be a few weeks, it may be several years. Individuals are not equally susceptible to the virus of rabies. A dog may be regarded as rabid who is not. It is not the first-come who is competent to decide by a post-mortem that an animal died rabid. The investigation of the microscopical changes necessary for such a decision takes time. No one is competent to declare after a bite from a dog that an individual is doomed to a painful death. It may be that a great boon has just been conferred upon suffering humanity, but the whole subject, as thus far presented, is enveloped in a sensational and theatrical atmosphere ill suited to sober science.

#### THE AMERICAN PUBLIC HEALTH ASSOCIATION.

THE American Public Health Association will hold its thirteenth annual meeting at Washington, D. C., December 8, 9, 10, 11, at the Hall of Willard's Hotel. Three very important topics have been selected by the executive committee for consideration and discussion at this meeting, namely:

I. The best form in which the results of registration of diseases and deaths can be given to the public in weekly, monthly, and annual reports.

II. The proper organization of Health Boards and local Sanitary Service.

III. Recent Sanitary experiences in connection with the exclusion and suppression of epidemic disease.

These three topics may legitimately be made to cover a wide range of sanitary science. Views will undoubtedly be freely exchanged as to the composition and work of a national health organization, as to the exclusion of cholera coming from Europe and of small-pox from Canada by "quarantine," by "inspection," or by the "quarantine of inspection;" as to the registration of vital statistics, and the "estimation" of death-rates.

On all these subjects the central government authorities, the medical profession, and the public at large should be glad to hear and heed the opinions and conclusions of sanitarians, some of whom have established and extended reputations, and who represent in the aggregate the different sections and varying interests of this vast but united country. It is well that at least once a year representatives of the yellow fever threatened Gulf States should meet in counsel with those of the small-pox or otherwise threatened States of the Northern Boundary, and that representatives of the interior States should confer with those of the seaboard. Each will find the other impressed with peculiar dangers and peculiar difficulties arising from the

peculiarities of his own surroundings, and a wider and clearer idea of what should be demanded and what may reasonably be expected from Sanitary Science and State Sanitation should result.

Dr. J. S. Billings, of Washington, will read a paper on Forms of Tables for Vital Statistics, which is sure to serve as a suggestive introduction to the first subject of discussion proposed by the executive committee. A paper, by Dr. P. H. Bryce, Secretary of the Ontario Provincial Board of Health, will doubtless perform the same office for the third subject selected; and the second subject need no introduction as, like the poor, we have it always with us and always unsatisfied.

The secretary of the Association announces eighteen other papers besides the two above mentioned.

The Committee on Disinfectants, which had already published and widely distributed a preliminary report, will present at this meeting a voluminous printed report embodying in full their investigations and conclusions on the subject of disinfection and disinfectants.

The sum of two thousand eight hundred dollars, offered by Mr. Henry Lomb, of Rochester, N. Y., will be awarded in first and second prizes for the most meritorious papers on four subjects as previously announced. Fifty-nine essays have been presented in competition on the following four subjects: "Healthy Homes and Foods for the Working Classes;" "The Sanitary Conditions and Necessities of School-Houses and School Life;" "Disinfection and Individual Prophylaxis against Infectious Disease;" "The Preventable Causes of Disease, Injury, and Death in American Manufactories and Workshops, and the best Means and Appliances for Preventing and Avoiding them." The successful essays will be presented to the Association, Thursday, December 10.

Such a body is wise in holding its meetings at Washington, and this thirteenth meeting is likely to be an unusually interesting and important one. The committee of arrangements have made liberal terms with the railroads, etc., and will send particulars to those desirous of profiting by them; the Secretary's address is 503 D Street, N. W., Washington, D. C.

### THE ANTIQUITY OF SYPHILIS.

ALTHOUGH historians have generally assigned the first appearance of syphilis in Europe to about the year 1495, when the disease was introduced into France at the end of the French expedition against the Neapolitans, it nevertheless has been demonstrated that venereal diseases have existed from the earliest period of the Indo-European race. Rosenbaum, in his "History of Syphilis in Antiquity," has shown that this malady took its origin in India, and was propagated in the line of the order of the succession of Oriental civilizations; that it had for its characters mucopurulent discharges, mentioned by Galen, Celsus, Aretaeus, Celsus, Aretaeus, Paulus of Aegina; inflammation of the testicles, or orchitis, induration of the testicles, and an aphthous affection of these glands, and ulcers of

the sexual organs, designated under the names *phagedena*, *anthrax*, *pustule* or *phyma*.<sup>1</sup>

Ulcers and vegetations about the anus and genitals (ficus, mariscus, alvus), pustules on the face and scalp, various skin diseases such as *mentagra*, *lepra*, and *psora*, are mentioned by Martial and Juvenal as the results of impure intercourse.

Inflammations of the throat, soft palate and tonsils, malignant ulcers of the throat are also alluded to by these writers and by Aretaeus, in connection with sexual vice, being sometimes secondary (as Rosenbaum shows) and sometimes primary, the effect of an abominable practice for which we have no modern name.

It is hard at the present day to imagine as possible among sane human beings certain revolting vices which were prevalent in the later periods of the Roman empire. The subject of sexual perversities constitutes a curious chapter in the annals of mankind, and might properly be considered under the head of the *Insane Neuroses*; certainly such depraved natures as those of Julia, Messalina, and Agrippina must be regarded as *morbid* as well as wicked. Certainly too, such practices as those indicated by the name *fellator*, *cunnilingus*, *cinaedus*, belong to the domain of mental pathology as well as to that of ethics.<sup>2</sup>

Rosenbaum has demonstrated the connection between these outrageous vices and the development of mucous patches of the utmost malignancy, as well as certain cutaneous diseases clearly of *syphilitic* character (especially associated with that form of pollution known as pederasty) and he has pointed out in the most striking manner the numerous references in the later Roman writers to every form of venereal disease.

It is to the pages of French authors that we naturally look for a thorough examination of such unclean subjects, and both Rosenbaum and Dupouy, in raking over the obscenities of past ages have done full justice to their task; the former in his "History of Syphilis in Antiquity," the latter in his work on the "Medicine and Manners of Ancient Rome."

### DR. WM. B. CARPENTER.

DR. WM. BENJAMIN CARPENTER, whose melancholy death by accident was announced by a cable dispatch last week, was born at Exeter, England, October 29, 1815. His early education was received in Bristol under the instruction of his father, the Rev. Lant Carpenter, a Unitarian minister. Devoting himself to medicine, he attended lectures at the Bristol Medical School, and hospital practice at the Bristol Infirmary. In 1834, he went to London and studied at University College and Middlesex Hospital. Here, while attending Dr. Grant's lectures on Comparative Anatomy, he imbibed that love for the subject which resulted in the production of his works on Physiology. In 1835, he pursued a course of studies in Edinburgh,

<sup>1</sup> See Edmund Dupouy, "Medicament Mours de l'Antien Rome," 16, 3, 8.

<sup>2</sup> The Hist on the Grain, W. W. Ireland, M. D.

at the Edinburgh University, and was elected President of the Royal Medical Society. Having spent two sessions in Edinburgh, he accepted the lectureship on Medical Jurisprudence in the Bristol Medical School, and commenced general practice in Bristol. The practice of medicine, however, was not after his liking, and he soon abandoned it, giving his time wholly to scientific studies. He wrote numerous scientific papers. His memoir on the Australian and Phillipian Foraminifera is valuable for the original matter which it contains. He published a "Manual of Zoology," of more than a thousand pages. In 1837, he began his "General and Comparative Physiology," the first edition of which appeared in 1838. This work, though long out of print, can hardly be said, even now, to be much behind the times; in fact, many of its masterly generalizations have become the current scientific coin of the day. Dr. Carpenter was appointed "Fullerian Professor of Physiology" in the Royal Institution, afterwards, Examiner in Physiology in the University of London. The first edition of his "Principles of Human Physiology" appeared in 1844. Eight editions of this work have been published. Very many now in practice remember well this work as being the leading text-book on physiology when they studied medicine. Dr. Carpenter, the last few years of his life, was hardly able to keep it abreast of the advancement of physiological science, and other more recent manuals of physiology are rapidly superseding the work of Dr. Carpenter. Dr. Carpenter became F.R.S. in 1841, and lecturer at the London Hospital; Lecturer on Geology at the British Museum in 1847, and in 1849, Professor of Medical Jurisprudence at the University College. He was for a while editor of the *British and Foreign Medico-Chirurgical Review*.

His treatise on the "Microscope and its Revelations," published in 1856, has gone through several editions. In 1850, he wrote his memoir to prove the "Correlation of the Vital with the Physical Forces." The substance of this view is "that the vital force, like the so-called physical force, has its origin in solar light and heat, and is not, as is commonly believed, a power inherent in the germ." Dr. Carpenter has ever been an earnest advocate of the doctrine of evolution, development by natural causes being clearly set forth in his "Principles of General and Comparative Physiology," and the genetic unity of all organic beings being a fundamental data of many of his later writings. He has always insisted that evolution is not only compatible with theism, but gives a powerful stimulus to the religious emotions, and an enduring sanction to ethical principles.

Dr. Carpenter's "Principles of Mental Physiology" is one of the most original of his works, giving the best exposition yet published of many psychological problems in their relation to nervous function, and it is used as a text-book by many of our higher institutions of learning. His more recent "Lowell" lectures on "Human Automatism" are in the same general line of exposition. His little work on the "Physiological Effects of

Excessive Indulgence in Alcoholic Liquors" has passed through a great many editions, and been translated into all the languages of Europe.

Dr. Carpenter will long be remembered for his writings in explanation of the phenomena of mesmerism or hypnotism, and spiritualism, in which he endeavors to account for these phenomena by the automatic action of the mind under the influence of suggestions, the will being in abeyance.

Dr. Carpenter was elected to the British Association of Science in 1872, and was subsequently occupied with investigations connected with deep sea-dredging expeditions, carried on in one of her Majesty's ships, and conducted by him in conjunction with T. Gwynn Jeffries, and Prof. Wyville Thomson. In 1882, Dr. Carpenter gave a series of lectures in this country in which he detailed the results of these investigations.

On the whole, Dr. Carpenter's life was an extremely industrious and useful one; as a lecturer and teacher he was eminently successful, and among his pupils have been the thinkers and the students of all lands where the English language is read; of unblemished character, and high ethical and spiritual convictions, his influence has been uplifting to humanity, and multitudes will mourn the loss which the world has sustained in his demise.

#### MEDICAL NOTES.

— Dr. William A. Guy of London, died recently, in his seventy-sixth year.

The death is also announced of Ernest Dubreuil, founder and publisher of the *Revue des Sciences Naturelles*, at Montpellier, in his fifty-sixth year.

— The Paris Municipal Laboratory has received a report concerning an epidemic of lead-poisoning which recently happened on a Norwegian vessel coming from Cadiz. Several of the crew exhibited symptoms of lead-poisoning, and the vessel was put into port in New York. The captain and several of his men were sent to the hospital at Coney Island. Two men died; the others recovered, after suffering severely. The affair was investigated, and it was ascertained that impure drinking-water was the cause of the catastrophe. The ship's tank was painted inside with red lead; the water became of a yellowish color. The Municipal Laboratory has issued a recommendation to landlords and all persons who have cisterns or water-reservoirs that resin or tar, dissolved in turpentine or benzine, should be used for painting them. It appears that, in Paris and its suburbs, a great many cisterns are painted with pigment containing lead.

— The municipal authorities of at least one city, Atlanta, Ga., have passed an ordinance which is deserving of general adoption. It prohibits hotel and boarding-house proprietors from turning off the gas at the meter during the night. One-half the deaths from asphyxia are believed to be due to the carelessness of the hotel men. A large number of travellers leave the gas burning dimly when they retire. Then

at a late hour of the night, the hotel man cuts the gas off in order to save his gas bill. The next morning when the early trains are arriving and departing, the landlord turns his gas on again. The burners are open in the rooms where men went to sleep with gas burning dimly. They are then asleep, and in a short time the gas overcomes them, and the next morning they are found dead in bed, and a coroner's jury says that they blew out the gas.

— It was determined by the Heidelberg Ophthalmological Society, soon after the death of Albrecht Von Graefe, to found, in honor of his memory, a gold medal to be awarded every ten years, for the most distinguished work done in ophthalmology. The first medal has just been unanimously decreed by the Society to Professor Helmholtz, of the Berlin University. After Graefe's death, a prize was also founded by the late Professor Welz, of Würzburg, to be awarded every third year for articles appearing in the *Archiv für Ophthalmologie*, founded by Graefe, which the Ophthalmological Society deemed most deserving of it. The fifth award has been made to Dr. Samuelson, of Cologne, the former prizes having been presented to Professor Leber, of Göttingen, to Dr. R. Weber, of Darmstadt, to Dr. Knies, of Zurich, and to Dr. Von Gülden, of Munich.

## NEW YORK.

— It is to be hoped that the meeting in reference to the abuses and misapplications of medical charity, to be held on the 20th, to which attention was recently called in the JOURNAL by Mr. Kellogg, organizing Secretary of the Charity Organization, will be productive of some good. More flagrant encouragement to these abuses is given by the wealthy New York Hospital than by any other institution in the city.

— The annual meeting of St. John's Guild was held November 9th. The Secretary's report showed that the summer work of the Guild began this year July 7th, and closed September 8th. During this period, the Floating Hospital made 35 trips from the city to the Seaside Nursery, on Staten Island, and carried in all — sick children and mothers — 26,280 persons, or about 4,000 more than during the previous season. At the Seaside Nursery, the inmates during the summer numbered 347 — 217 children and 130 mothers, and there were four deaths.

— The Annual Reception at the Mount Sinai Hospital occurred November 8th. — In the buildings are accommodations for 170 patients, and about that number are constantly in the wards. An average of 150 out-patients a day are treated in the dispensary connected with the hospital. For in-patients, the daily cost is a little less than one dollar a head, and 97 per cent. of the hospital service is gratuitous. The flowers and plants which were sent by the ladies to decorate the main entrance and corridors for the reception, were afterwards distributed among the patients in the wards.

— The attention of the Board of Health having been called to the fact that it had recently been ascertained

that some milk in Philadelphia was contaminated with boracic acid, for the purpose of keeping it sweet for a long time, Dr. Edson has reported that the milk inspectors were aware of the occasional use of the acid in this way. He stated that it was first employed in Boston, and that the practice was first introduced into New York about two years ago. The adulteration, however, was soon detected, and the offenders were prosecuted; and, as far as known, there has been no resort to it since. Between 4,000 and 5,000 inspections of milk have been made this year, and 7,000 samples of milk have been analyzed without finding a trace of boracic acid. The use of the acid is regarded as highly pernicious, as it is said to be liable to result in Bright's disease.

— At a meeting of the Society of Medical Jurisprudence and State Medicine, held November 12th, Dr. E. C. Harwood on behalf of a committee previously appointed to consider the subject, made a preliminary report in favor of cremation, stating that for sanitary and other reasons the disposal of dead bodies by cremation is much to be preferred to burial, and should be recommended in all cases. The report further recommended the passage of a law by the Legislature requiring that the bodies of all persons dying of contagious or infectious diseases, and also of all whose remains are disposed of at public expense in cities, should be cremated. As all the members of the Committee had not been present at all its meetings, it was voted that the report should be referred back to the Committee for further consideration, and that it should be submitted again at the next meeting of the Society.

— At the same meeting, Dr. J. F. Fruitnight read a paper on "Compulsory Vaccination," in which he referred to the opposition which is manifested in Montreal, and even in New York, in some quarters, to vaccination, and urged the medical profession of the city to adopt such means as will counteract the effects of the hostile movement. As vaccination provides the only effectual protection against small-pox, the sooner this was understood, the better it would be for the health of the entire community. Dr. Fruitnight related the history of the attempts of the European Governments to control the disease of vaccination, and argued that the results obtained by such measures abroad favor the adoption of some plan of compulsory vaccination in this country. While much good had undoubtedly been achieved through the exertions of the health authorities in many of our cities in the direction of protecting the people against the ravages of small-pox, he thought that the matter should not be left to individual inclination, and that these efforts should be seconded by the strong hand of the law. In the discussion which followed the reading of the paper, Dr. J. B. Taylor, of the Health Department, spoke in favor of the plan of compulsory vaccination, and gave statistics concerning vaccination in the city of New York, which showed that the opposition to the measure among people living in the poorer districts is at present, very much less than it formerly was.

## Miscellany.

### PROFESSORSHIP OF THEORY AND PRACTICE, LONG ISLAND COLLEGE HOSPITAL.

THE Chair of Practice in the Long Island College Hospital, made vacant by the death of Prof. S. G. Armor, is to be filled, and suitable candidates are desired to present themselves. According to the Charter, all appointments, to either faculty or vacancies therein to be filled, shall be thrown open to the whole medical profession, as recognized by the American Medical Association; and it shall be the duty of the Council, with the faculty of the department in which such vacancy exists, or such addition is to be made, to institute such a comparison of the relative claims and merits of all applicants as shall secure the most available and suitable persons for such positions. All nominations for such appointments shall be made in joint meeting by the Council and faculty of the department to which such appointments are to be made, and shall be laid before the Board of Regents at a regular meeting, whose approval, by a majority of the members present, shall be necessary to a final appointment; and no appointment to either faculty shall be made except in the manner herein provided. All medical and surgical assistants shall be selected and appointed in the same manner, and, together with the members of both faculties, shall hold their appointments subject to the annual election by the Regents.

All communications should be addressed to Dr. A. J. C. Skene, Chairman of Committee on Appointments.

### PHYSIOLOGY BY ROTE.

In an educational paper in a recent number of *Science*, the writer gives an example taken from a composition written by a boy in a New England grammar school, which illustrates the amount of benefit to be derived from anatomical, or indeed, any other sort of scientific instruction from a teacher who knows the subject only from a text-book, and therefore imparts it only from that source. From the nature of the subject, this sort of teaching is more apt to be given in physiology in the public schools than in the other natural sciences. We make room for this essay, which is upon "Bones." Fortunately, there is enough nature left in the boy to keep him from being priggish.

"Bones are the framework of the human body. If I had no more bones in me, I should not have so much shape as I have now. If I had no bones in me, I should not have so much motion, and grandma would be glad; but I like motion. Bones give me motion, because they are something hard for motion to cling to. If I had no bones, my brains, heart, lungs, and larger blood-vessels would be lying round in me sort of loose-like, and might get hurt; but not much, lest it is hard hit.

"If my bones were burned, I should be all brittle, and you could crumble me up, because all the animal would be out of me. If I was soaked in a kind of acid, I should be kinder. Teacher showed some bones that had been soaked. I could tie a knot in one. I had rather be soaked than burned.

"Some of my bones don't grow snug, and close to my other bones, like the branches to a trunk of a tree do; and I am glad they don't; for if they did, I could not play baseball, and other good games, I know. The reason they don't grow that way is because they have

joints. Joints is good things to have in bones. There are two or three kinds. The ball-and-socket joint, like my shoulder, is the best. Teacher showed it to us, only it was the thigh-joint of a cow. One end was round, smooth, and whitish; that was the ball end. The other end was saucer-like: that is the socket, and it oils itself.

"Another joint is the hinge-joint, like my elbow. It swings back and forth oiling itself, and never creaks like the school-room door does. The other joint ain't much of a joint. That is in the skull, and it don't have no motion.

"All of my bones put together in their right places makes a skeleton. If I leave out any, or put some in the wrong place, it ain't no skeleton. Cripples and deformed people do not have no skeletons.

"Some animals have their skeletons on the outside. I'm glad I aint them animals; for my skeleton, like it is on the chart, would not look well on my outside."

## Correspondence.

### COCAINE IN DENTITION.

Boston, Nov. 17, 1885.

MR. EDITOR.—In answer to the query of Dr. Wigglesworth in your last issue as to the use of cocaine in teething, I would state that while I have not used it in primary dentition, in second dentition I have with marked alleviation of the pain and tenderness.

Yours very truly,

EDWARD J. FORSTER, M.D.

### A NOTE FROM THE BOSTON BOARD OF HEALTH CONCERNING CONTAGIOUS DIS- EASES.

Boston, November 14, 1885.

MR. EDITOR.—The Boston Board of Health respectfully begs to call the attention of physicians to the subjoined Statute Law relating to contagious diseases and to say that the non-compliance with this law by so many, either by total neglect to report or tardily reporting their cases, has served largely to defeat the object of the law which is to prevent the spread of contagious diseases, especially through the public schools.

Under the following law the Board of Health especially includes small-pox, scarlet fever, diphtheria, measles, typhoid fever, typhoid fever and cholera, and although we are aware of the difficulty in some cases of making an early diagnosis, yet we should reasonably expect the cases to be reported as soon as they are determined.

It is hoped that all physicians will at once see the importance of a ready compliance with this law. By such compliance they will aid the Board of Health and the School Committee in their efforts to prevent the spread of these diseases and render prosecution for non-compliance unnecessary.

THE BOARD OF HEALTH,

By S. H. DUGGIN, M.D., Chairman.

[CHAP. 98.]

AN ACT concerning Contagious Diseases.

Be it enacted, etc., as follows:

SECT. 1. When a householder knows that a person within his family is sick of small-pox, diphtheria, scarlet fever or any other disease dangerous to the public health, he shall immediately give notice thereof to the selectmen or board of health of the town in which he dwells, and upon the death, recovery or removal of such persons, the rooms occupied and the articles used by him shall be disinfected by such householder, in a manner approved by the board of health. Any person neglecting or refusing to comply with either of the above provisions shall forfeit a sum not exceeding one hundred dollars.

SECT. 2. When a physician knows that a person whom he is called to visit is infected with small-pox, diphtheria, scarlet

fever or any other disease dangerous to public health, he shall immediately give notice thereof to the selectmen or board of health of the town; and if he refuses or neglects to give such notice he shall forfeit for each offence not less than fifty nor more than two hundred dollars.

SECT. 3. The boards of health in the several cities and towns shall cause a record to be kept of all reports received in pursuance of the preceding sections and such record shall contain the names of all persons who are sick, the localities in which they live, the diseases with which they are affected, together with

the date and the names of the persons reporting any such cases. The boards of health shall give the school committee immediate information of all cases of contagious diseases reported to them according to the provisions of this act.

SECT. 4. The secretary of the Commonwealth shall furnish the boards of health with blank-books for the record of cases of contagious diseases as above provided.

SECT. 5. Sections seventy-eight and seventy-nine of chapter eighty of the Public Statutes are hereby repealed. [Approved March 21, 1884.]

## REPORTED MORTALITY FOR THE WEEK ENDING NOVEMBER 7, 1885.

## Population by State Census, of May 1st, 1885.

Deaths reported 1,818; under five years of age 619; principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, levers, and diarrhoeal diseases) 336, consumption 343, lung diseases 198, diphtheria and croup 153, diarrhoeal diseases 55, typhoid fever 38, scarlet fever 22, malarial fever 31, whooping-cough 13, cerebro-spinal meningitis eight, erysipelas four, small-pox one, puerperal fever one, typhus fever one. From malarial fever, Brooklyn nine, New Orleans eight, Baltimore seven, New York five, Philadelphia and Nashville one each. From scarlet fever, New York six, Philadelphia five, Brooklyn, Boston and Baltimore two each, Charleston, Fall River, Springfield, Gloucester and Trenton one each. From whooping-cough, New York seven, Brooklyn four, Baltimore two, Taunton one. From cerebro-spinal meningitis, New York four, Boston, Fall River, Taunton and Brockton one each. From measles, New York, Brooklyn, and Boston one each. From erysipelas, New York two, Brooklyn and Springfield one each. From small-pox, New York one. From typhus fever, New York one. From puerperal fever, New York one.

In 108 cities and towns of Massachusetts, with a population of 1,336,791 (population of the State 1,941,650), the total death-rate for the week was 16.26 against 15.08 and 14.38 for the previous two weeks.

For the week ending October 17th, in the Swiss towns, there were 22 deaths from consumption, lung diseases 19, diarrhoeal diseases 10, whooping-cough three, diphtheria and croup two.

The death-rates were: at Geneva 16.2; Zurich 9.7; Basle 28.4; Berne 16.4.

For the week ending October 24th, in the Swiss towns, there were 22 deaths from consumption, lung diseases 13, diarrhoeal diseases 13, small-pox three, scarlet fever one.

The death-rates were: at Geneva 15.2; Zurich 5.8; Basle 11.3; Berne 16.4.

In the 28 greater towns of England and Wales, with an estimated population of 8,266,146, for the week ending October 17th, the death-rate was 17.7. Deaths reported 3,025; infants under one year of age 804, acute diseases of the respiratory organs (London 201, diarrhoea 75, measles 66, whooping-cough 59, scarlet fever 58, diphtheria 39, fever 38, small-pox (Nottingham and Manchester one each) 2.

The death-rates ranged from 9.0 in Underfield to 27.0 in Preston; Birkenhead 19.1; Birmingham 17.1; Hull 14.0; Leeds 18.8; Leicester 11.1; Liverpool 19.9; London 17.2; Manchester 21.9; Nottingham 14.3; Sheffield 16.7.

In Edinburgh 17.3; Glasgow 20.5; Dublin 21.1.

In the 28 greater towns of England and Wales, with an estimated population of 8,266,146, for the week ending October 24th, the death-rate was 15.3. Deaths reported 3,157; infants under one year of age 787, acute diseases of the respiratory organs (London 246, measles 67, scarlet fever 57, whooping-cough 57, diarrhoeal diseases 72, fever 49, small-pox (Liverpool three, Sunderland one each) 4.

The death-rates ranged from 11.1 in Norwich to 23.2 in Bolton; Birmingham 15.7; Bradford 17.6; Hull 14.0; Leeds 17.4; Leicester 14.9; Liverpool 22.1; London 18.6; Nottingham 14.8; Sheffield 18.1.

In Edinburgh 17.7; Glasgow 19.6; Dublin 23.8.

The meteorological record for week ending November 7th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole of the United States Signal Corps:—

Week ending	Barometer.				Thermometer.				Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall.

# OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM NOVEMBER 7, 1885, TO NOVEMBER 13, 1885.

BAILLY, E. L., surgeon and colonel. Relieved from duty as attending surgeon, San Francisco, Cal., and ordered for duty as medical director, Division of the Pacific and Department of California.

NOREIS, BASIL, surgeon and lieutenant colonel. Ordered for duty as medical director, Department of the Columbia.

McKEE, J. C., surgeon and major. Ordered for duty as attending surgeon and examiner of recruits, Boston, Mass.

VOLLUM, E. P., surgeon and lieutenant colonel. Ordered for duty as medical director, Department of Texas.

SMITH, J. R., surgeon and lieutenant colonel. Ordered for duty as attending surgeon, New York City, N. Y.

ALEXANDER, R. H., surgeon and lieutenant colonel. Ordered for duty as medical director, Department of Arizona. S. O. 260, A. G. O., November 11, 1885.

KANE, JOHN J., assistant surgeon and captain. Ordered for duty as post-surgeon, Fort Ringgold, Texas. S. O. 141, Department of Texas, November 4, 1885.

EBERT, R. G., assistant surgeon and captain. Ordered from Camp Grant, Riverside Park, New York City, to Fort Hamilton, New York Harbor, for duty. S. O. 237, Department East, November 5, 1885.

BUSHNELL, G. E., assistant surgeon and first lieutenant. Assigned to duty at Camp Grant, Riverside Park, New York City. S. O. 237, Department East, November 5, 1885.

# OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING NOVEMBER 14, 1885.

SAVRE, J. S., assistant surgeon. Detached from Naval Hospital, Mare Island, and ordered to the "Onahau."

DIXON, W. S., surgeon. Detached from coast survey steamer "Hassler," upon reporting of his relief, Past Assistant Surgeon D. O. Lewis, and wait orders.

LEWIS, D. O., past assistant surgeon. Detached from naval rendezvous, San Francisco, and ordered to relieve W. S. Dixon, steamer "Hassler."

DESGAR, J. S., medical director. Ordered to naval rendezvous, San Francisco, to relieve Passed Assistant Surgeon D. O. Lewis.

# OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE FOR THE WEEK ENDING NOVEMBER 7, 1885.

PROBERT, J. M., passed assistant surgeon. Upon the closure of the Cape Charles Quarantine Station to proceed to Norfolk, Va., for duty, November 5, 1885.

BUTLER, K. P., assistant surgeon. Resignation accepted, as tendered, by the Secretary of the Treasury, to take effect November 25, 1885, November 3, 1885.

## SOCIETY NOTICE.

NORFOLK DISTRICT MEDICAL SOCIETY. A meeting for Scientific Improvement will be held at Room 7, Palladium Hall Building, corner of Warren and Dudley Streets, Roxbury, on

Tuesday, November 24th, at 7.45 P. M. Communications: I. Exhibition of a New Dressing for Fracture of the Clavicle, Edw. T. Williams, M.D. II. Arsenical Poisoning, Joseph Steadman, M.D. III. Multiple Neuritis, Robert Bell, M.D. Particular attention is called to the new place and time. A cordial invitation is extended to members of other Districts to be present at the meetings of the Norfolk District, and participate in its discussions. S. ALLEN POTTER, M.D., Secretary.

## RESOLUTIONS ON THE DEATH OF DR. JOSEPH R. DRAPER.

At a meeting of the South Boston Medical Club the following preamble and resolutions were adopted:—

Whereas, Death has removed from our midst our much esteemed friend and colleague, Dr. Joseph R. Draper, and whereas it is fitting that this Society, of which he was one of the founders and a former president, should express their feeling of sorrow at this great loss, therefore:

Resolved, that we gladly testify to our appreciation of his great professional skill, his readiness to advise when called upon by any of us, his honesty of principle toward his medical brethren and toward his patients, his affability at our social gatherings, all of which we shall ever hold in grateful remembrance.

Resolved, that the death of Dr. Draper is a loss to the community in which he lived and for which he worked so many years; but that his loss will be felt more directly by his professional associates.

Resolved, that a copy of these resolutions be put upon the records of this Society, a copy be forwarded to his afflicted family, a copy be published in the *South Boston Inquirer* and in the *Boston Medical and Surgical Journal*.

F. G. REED, Secretary.

## DEATH.

Died in Leicester, Mass., November 12, 1885, George Otis Warner, M.D., M.M.S.S.

## A CASE OF STRICTURE OF BOTH URETERS, DOUBLE HYDRONEPHROSIS, LEFT LUMBAR NEPHROTOMY. — DEATH FROM UREMIA FORTY-EIGHT HOURS AFTER OPERATION.

BY F. S. WATSON, M.D.,

*Surgeon to Out-patients, Boston City Hospital.*

EARLY in May of this year, I was called in consultation to a young man of twenty-two years of age, whose case was one of such unusual character, that it seems desirable to report it somewhat in detail.

The history of the illness is briefly as follows: A year previous, the patient had an attack of renal colic on the *right* side; passed soon afterwards two small calculi, and the urine contained sand for a few weeks following. About this time he acquired a gonorrhoea; cystitis resulted, but all symptoms left the patient at the end of six months, and he considered himself perfectly well, and for the last six months has not been conscious of any trouble. During this time he was actively engaged in study and athletic sports.

Five days before I saw him he went to a boat race, became chilled while there; on coming home had a severe chill, accompanied by renal colic of the *left* side, nausea, and a sudden diminution in the quantity of urine. During the next day, a swelling made its appearance in the left lumbar region, extending forward into the left hypochondrium. This slowly increased in size, and on the fourth day, was a large, tense tumor, of the size of a fetus' head at term. It was then aspirated, and about six ounces of urine were withdrawn from it. It rapidly refilled, however, and on the following morning, when I first saw the patient, had regained the size already mentioned. In the meantime, the quantity of urine passed into the bladder continued to be from three to six ounces only, in each twenty-four hours. The patient sank rapidly, with hiccough, vomiting of dark matter, as prominent symptoms, and became unconscious during the fourth day. Constipation had existed from the first. On the morning of the fifth day, he could, however, be aroused sufficiently to answer questions. Pulse, 138, regular, and fairly strong; temperature, 97° F.; tongue furred; persistent hiccough and vomiting, and slight twitchings of the muscles of the face and forearms. Bladder empty; no obstruction in the course of the urethra. The tumor as already described, tense and fluctuating, extending from the eleventh rib to the crest of the ilium, and very prominent in front. The urine was pale, cloudy, owing to the presence of pus, and crystals of its triple phosphates, and had a sp. gr. of 1010. No casts, and no concretions, and only a trace of albumen. There was no disease of the other organs detected.

The diagnosis was made of hydronephrosis of the left kidney, due to an obstruction in the course of the ureter, probably stone, and chronic disease of the right kidney, nature conjectural. The cyst was so tense that its rupture was felt to be imminent; and it was with a view to avoiding this catastrophe, as well as in the hope of finding that the obstruction was of a remediable nature, that lumbar nephrotomy was advised, although an unfavorable prognosis was given, based upon the patient's general condition, the probable diseased condition of the other kidney, and the chance of finding that the obstruction was not removable.

The cyst was reached without difficulty, or hemor-

rhage of consequence, by an incision four finger-breadths from the vertebral spines, extending from the twelfth rib to the crest of the ilium. Its walls were tensely stretched, but not ruptured at any point, although almost as thin as tissue paper. Before opening it, a considerable quantity of urine was noticed in the muscular inter-spaces and tissues in the vicinity of the tumor, and the question occurred if this might not have escaped from the aspirating punctures of the day before, upon the refilling of the cyst.

The cyst was now incised, and about a quart of urine escaped. Upon inserting the finger into the calyx of the kidney through this wound, it entered a very large cavity, the further limits of which could not be felt in any direction. Neither the orifice of the ureter nor any normal structures were recognizable, nor could any stone or other obstruction be detected, although a long probe was pushed far down into what was taken to be the course of the ureter.

The only thing left to do was to stitch the calyx of the kidney to the sides of the wound, and to arrange for permanent drainage through the loin, which was accordingly done. An antiseptic dressing completed the operation. Large quantities of urine continued to flow through the drainage tube. The shock was slight; pulse after the operation, 140. The temperature rose in the evening to 101° F.; vomiting, hiccough, and constipation ceased for about twelve hours after the operation. No more urine has passed into the bladder.

The patient partially recovered consciousness on the following morning, but gradually returned to his former condition, and died about forty-eight hours afterward with uramic symptoms.

## AUTOPSY.

The autopsy which was made by Dr. W. W. Gannett, showed appearances unusual in this class of cases. The right kidney was converted into an oval sac 9.5 by 6 cm., there being a thin layer of renal substance of a pale gray color, and increased density on its inner surface. There was a narrowing of the ureter 1.5 cm. below the pelvis, with dilatation above this point, the ureter below being of the normal calibre.

The left kidney was much enlarged, measuring 19.5 by 11 cm. The pelvis and calyces were greatly dilated, a portion only of the renal substance remaining on the inner surface. The ureter at the point of origin from the pelvis, measured 1 cm.; immediately below this point it was widely dilated, being about the size of the small intestine, and measuring when laid open, about 8 cm. in width. Two centimeters above the bladder, there was a stricture of the ureter large enough to admit only a fine knitting needle. Below this, the ureter was of the normal calibre. No calculi were found, and nothing on the outside of the ureters to suggest that there had been any cause of stricture from without.

The right kidney had probably been rendered incapable of performing its function at the previous attack of renal colic. The left kidney had not been suddenly rendered useless, but the marked degree of hydronephrosis and dilatation of the ureter had required considerable time for their development. Whether the obstruction leading to the stricture on the left side was due to a calculus is impossible to say. The patient died from uræmia, due to the small amount of secreting surface remaining.

I have found in the literature relating to this sub-

ject, only four cases which at all closely resemble this one just reported, and have thought it worth while to present a short summary of them.

1. Kroner reports a right-sided hydronephrosis due to a valve-like formation of the mucous membrane of the pelvis of the kidney, the nature and cause of which are not accurately described in the *Arch. für Gynäkologie*, 1881, xvii., 87, 109.

This patient, a young woman, recovered after the kidney had been drained by ventral median operation, a nephrotomy being performed later, from which the patient was also restored.

2. A case somewhat resembling the one reported by me this evening, is published by L. Galliard in the *Progrès Médical*, 1880, viij., 868. The patient was a man of sixty, who, until within a day or two before his entrance to the hospital, had enjoyed excellent health, and had never had any symptoms pointing to renal calculus, or referable to the secrete-urinary tract. He complained, on entrance, of a severe pain localized about the lumbar region, and a fluctuating tumor could be made out there. There was pus in the urine, and the patient was constipated. The tumor increased slowly in size for four days, when he died uræmic. The autopsy showed the left kidney to be the seat of an extensive hydronephrosis, due to the presence (according to the reporter) of an inflammatory stricture one and a half centimeter long, in the ureter, just below its exit from the pelvis of the kidney. The mucous membrane above the stricture presented the characters of chronic inflammation, and there was an extensive formation of connective tissue at the site of the stricture. The other kidney is not said to have been diseased.

3. *Apollon, Société Anatomique*, lix, 214, has a case of a robust-looking man of fifty-four years of age, who gave a history of having passed renal calculi at intervals during the two years previous. He had passed no urine for five days before, and had, until ten days ago, been quite well. At that time he began to notice a sense of oppression in the abdomen. On the twelfth day in the hospital, pulmonary œdema came on; and on the sixteenth day after entrance, he died suddenly, having only passed four hundred grammes of urine in the last day. He was comatose during the last four days. The autopsy showed obliteration of both ureters (at what points is not mentioned), with formation of connective tissue at the points affected, and inflammation of the mucous membrane.

4. The last case is taken from *St. George's Hospital Reports*, Vol. x., 1879, p. 350. This was a young man aged twenty-three, who had catarrhal symptoms of nose, throat and bronchi, night sweats, and rapid wasting for a week. At time of entrance, the urine contained no albumen. Under treatment, he improved for three weeks. Albumen then appeared in the urine. Edema of the lungs and diarrœa, and œdema of the tonsils followed, and he died one month from date of entrance. (No mention is made of the quantities of urine passed). After death, there was found a stricture of the left ureter, about four inches below its exit from the kidney, above which the mucous membrane was reddened, thickened, and ulcerated. Both kidneys were enlarged, and the seat of a diffuse nephritis. The lungs were œdematous. It was thought that the stricture was not of very recent date, but had been rendered impervious by the inflammatory changes.

Cases in which stones have been present in the ureters, diminishing their calibres, or in which the flow of

urine through them has been impeded or stopped by the pressure of new growths or strictures, resulting from the presence of abscesses or new growths in their vicinity, are not especially uncommon. But I have been unable to find other than these cases of strictures of this nature, in the published reports, and offer my own to the Society in the hope that those who have had a larger experience may have met with similar conditions, which they will be ready to impart.

## SEVERE AND PROLONGED NEPHRITIC COLIC WITH RECOVERY.<sup>1</sup>

BY F. GORDON MORRILL, M.D.

THE patient, married, aged twenty-four, was confined with her first child, April 20, 1884. A fairly prompt recovery followed a tedious labor which terminated in instrumental delivery. A laceration of the cervix of considerable extent was left to itself, it being deemed wise to avoid operative measures until the patient's general condition should improve with change of air, her usual health being far from robust, although no special cause existed, so far as known. From June 10 (the date of her leaving the city), until the latter part of October, I lost sight of her; but immediately upon her return she consulted me, complaining of frequent and painful micturition, which had then existed about a fortnight. Examination of the urine early in November showed slight acidity, a moderate amount of pus, and an excess of epithelium of a large variety, which may have been either vesical or vaginal—as the precaution of using a douche previous to passing the specimen examined was neglected. The usual treatment by sitz baths, alkalis and diluents having failed to give relief, and the pain being of such a nature as to raise a suspicion of the presence of a vascular tumor of the urethra, an examination was made November 10, but nothing beyond a gravid uterus of two months was discovered. This may have been the immediate cause of trouble which must have appeared sooner or later, as the subsequent history of the case will show. I have neglected to state that previous to her confinement, the patient's only illnesses had been an acute rheumatic fever, and a sickness which followed a fall upon the ice in girlhood, the nature of which can only be guessed at, but which necessitated the application of leeches over the course of the right ureter. The original diagnosis of cystitis was apparently confirmed—the acidity of the urine (considering the sex of the patient) not to my mind balancing the rational signs and absence of anything in the urine indicating renal trouble. Within a fortnight the pain and tenderness (the latter now involving the rectum at times) had become so intense as to require  $\frac{3}{4}$  of tr. opii by the rectum every day to obtain relief, besides grs. ii of morphia by the mouth. Anorexia and a considerable loss of strength accompanied this condition of things, and the condition of the urine meanwhile remained unchanged. All treatment except outward applications and opiates had to be abandoned on account of persistent nausea, and matters grew steadily worse until December 10, when she complained of pain in the right lumbar region. On the 12th, a severe and prolonged chill was followed by a pulse of 135, and a temperature of 101° F. Previous to this neither pulse or

<sup>1</sup> Read before Boston Society for Medical Improvement, October 26th, 1885.

temperature (aside from weakness of the former) had shown any deviations from normal.

The pain was now of the most agonizing description, and followed the course of the ureter from the right kidney to the bladder, and thence to the meatus. At times it preceded or immediately followed micturition, and again it would come on entirely irrespective of the act. The urine now showed pus in clumps, and renal and caudate epithelium. It was still acid, and the quantity was increased. *No casts or crystals of any description were detected by repeated examinations.*

The rectal injection of laudanum had now to be abandoned on account of producing irritation, and six grains of morphia (hyperdermically and by the mouth) were required to give only partial relief. But little nourishment could now be taken, and brandy in large doses was required to support the strength. On the 14th, Dr. Hodges saw the patient with me, and agreed in the diagnosis of acute pyelitis, and that to support the patient's strength and relieve pain, was all that could be done at that time in the way of treatment. November 15, an excellent trained nurse was in attendance (against whose employment the patient had hitherto obstinately fought) and for the first time morphia enough (grs. 10 per diem) was used to subdue the pain, and the amount of nourishment was increased through her tact and perseverance. Chloral in 5-ss doses was employed to obtain sleep. December 20th there was no change in her condition aside from loss of strength, and on the 21st, the urethra was dilated under ether, and a careful examination made of the interior of the bladder. Nothing was discovered here, or in the lumbar region or course of the ureter to shed any light upon the cause of the pain. Dr. Wood examined the urine, and the results obtained were identical with my own, save that one fibrinous cast was discovered. His opinion was that a pyelitis of the right kidney existed, and that the absence of the microscopic proofs of a calculus or gravel might be due to the patient having been so long in the recumbent position. December 29th, it was thought best to empty the uterus, in hopes that removing the pressure upon the ureter might afford relief, the patient now being four months pregnant. Dr. Boardman saw the patient with me, and under ether another careful examination was made with negative results. There was no renal tumor, no stone in the bladder or ureter — in short, nothing was discovered beyond the fact that the uterus was antverted, and that the foetal head could be easily caught between the finger of one hand in the vagina, and the other hand placed upon the abdominal walls. A sound was introduced into the womb and carefully swept around. Only a slight hæmorrhage followed. In the evening what appeared to be uterine pains caused me to give a full dose of ergot; but labor was delayed until January 1st, when a full dose of ergot was again given and the foetus removed. An adherent placenta together with considerable loss of blood and what almost amounted to collapse on the part of the patient were attendant features of the not too cheerful scene, and hyperdermic injections of brandy and ether were required to restore anything resembling a regular pulse. The uterus fortunately contracted firmly, and upon consciousness being restored the patient expressed great relief so far as her pain in the lumbar region was concerned; but the pain in the bladder and urethra continued severe. January 4th the lumbar pain returned and on the 8th, twenty-

one grains of morphia hyperdermically and  $\frac{3}{ii}$  of chloral were administered in twenty-three hours to obtain only brief intervals of freedom from acute suffering. This sudden and enormous increase of the amount of morphia required was accompanied by the excretion of more than double the normal amount of urine, which was comparatively free from sediment of any kind. On the night of the 8th, all pain suddenly disappeared, and during the next three days the urine was loaded with pus, and uric acid gravel was passed in enormous quantities, but nothing like what is ordinarily recognized as a "concretion" appeared. The morphia was immediately reduced to grs. iii. per diem, and at times even less, sleep being procured by the use of chloral. The appetite and strength now began to improve, and the patient was most eager to abandon the use of morphia. The urine was speedily rendered alkaline by lithium, and the only pain remaining (January 18th) was apparently occasioned by spasm of the urethra following micturition, and requiring about gr. i. of morphia every twenty-four hours. All trouble gradually ceased after this, and examination of the urine in February showed no trace of pus or crystals or casts, and the patient has remained free from any urinary symptoms to present date. I regret that the gravel passed was not saved after each micturition, but this being unfortunately the case, I can only roughly estimate the amount as between two and three even teaspoonfuls. I have not mentioned the particulars regarding the treatment, aside from the amount of morphia and chloral administered; and will briefly state that lithium, urethral suppositories of cocaine (when the pain seemed to centre at the neck of the bladder) and various other remedies were used as the symptoms indicated, without the least apparent effect. The two points of interest (aside from the severity of the symptoms and their long duration) are:—

The reference of the pain to the urethra when the cause was renal, this being analogous to the retraction of the testicles in males.

The absence of microscopic proof of renal trouble when the disease had existed for so long a time.

#### LUXATION OF LENS BENEATH TENON'S CAPSULE.<sup>1</sup>

BY G. F. WADSWORTH, M.D., BOSTON.

As I do not remember to have seen any report of the luxation of a lens beneath Tenon's capsule, it seems worth while to put the following case on record:

James T., aged forty-seven, entered the City Hospital March 18, 1881, by advice of his family physician, for emulsion of his left eye. Two weeks before, he had received a blow on this eye from the horn of a cow, which had destroyed its sight. Since the injury the eye had been painful, and any attempt to use the other eye had caused pain in it also.

The cornea was slightly hazy; a narrow strip of iris was visible at the inner and lower edge of the anterior chamber, elsewhere the area behind the cornea was dark and partly filled with blood. Near the inner edge of the cornea was an irregular cicatrix in the conjunctiva, and a few dark irregular lines in the tissues beneath suggested a partial rupture of the sclera. Upward and outward, between the external and superior recti, beginning  $\frac{1}{16}$  to  $\frac{1}{2}$  from the edge of the cor-

<sup>1</sup>Read before the American Ophthalmological Society, July 16, 1885.

nea, was a rounded swelling, of the size and shape of the crystalline lens. Oblique light showed the swelling to be translucent. It was evidently covered by a layer of dense tissue.

I supposed the lens lay between the sclera and Tenon's capsule, and that on division of the capsule, during enucleation, it would escape; but this proved not to be the case. In the operation the hook glided behind the swelling, and it remained in position when the globe was removed. The eye was hardened in Müller's fluid and alcohol, and later divided antero-posteriorly through the swelling.

Microscopically, no sign of a rupture in the sclera could be seen. The lens appeared to lie against its outer surface; or rather it seemed as if the greater portion of the sclera lay between the lens and the vitreous chamber, while a thin layer of its outermost fibres passed outside the lens and held it in place.

On thin sections through the whole globe, which Dr. H. P. Quincy kindly made for me, the microscope showed, however, the true condition. The sclera had been ruptured near the anterior edge of the ciliary body, and the wound had been completely closed by cicatricial tissue. The whole thickness of the sclera ran along on the inner side of the lens, and the fibrous layer on the outer side of the lens, which curved round the lens behind, and was there united firmly to the sclera by inflammatory exudation.

## RECENT PROGRESS IN PATHOLOGY AND PATHOLOGICAL ANATOMY.<sup>1</sup>

BY WILLIAM F. WHITNEY, M.D.

### EXPERIMENTAL STUDIES ON THE FORMATION OF THROMBI.<sup>2</sup>

Up to the present time this subject has been observed only in the cold-blooded animals, on account of the technical difficulties which stood in the way of using the mammals. However useful the former may be, in many respects they are unsuitable, especially when it becomes a question of the part played by the third formed element of the blood, the so-called blood plates. For these an almost specific rôle in the coagulation of the blood both within and without the vessels, has been claimed. They are supposed to change rapidly, bring about the fibrin fermentation, precipitating the fibrin upon themselves, from whence it shoots out in thread-like processes. In short, they control the entire process of extra-vascular coagulation. In the formation of the thrombus, they adhere to every foreign body within the vessel, and to a wounded wall. They cause the primary closure of a wound, and finally make up the white thrombus, which has hitherto been regarded as an accumulation of white cells.

The author of this article have occupied themselves especially with this new theory of coagulation, and do not find that it can be justified. They have found that the fibrin threads do shoot out like needles, and in this respect coagulation is like crystallization; but

that the relationship of it to the blood plates is an accidental one. And further they deny, on the chemical side of the question, that they exert a specific or fermentative action in the sense of the term employed by A. Schmidt.

At the head of their investigations they placed a long series of observations on the circulation in warm-blooded animals, and endeavored to study the relation of disturbances from the very beginning. They were able to accomplish this by entirely immersing a guinea pig or dog in a bath of warm salt solution, of the strength of three-quarters of one per cent. The omentum or mesentery was drawn out beneath the fluid and directly observed by plunging the tube of the microscope down to it. In this way circulation could be maintained for hours. The normal condition was characterized by a red stream in the centre flowing with such swiftness that the separate elements could not be distinguished. Between this and the walls of the vessel, especially noticeable in the veins, a clear zone of plasma was to be made out, about the width of a leucocyte. In this, one of these occasionally rolled along, but much more slowly than the elements in the axial current.

By simply letting the water run out of the bath the vessels could be subjected to various degrees of irritation. Even when this was very slight, the arrangement, as described above, was essentially changed. If the vessels were dried for an instant, or the bath made too warm, a marked accumulation of the colorless cells took place in the plasma zone, rolling over each other two or three deep, and thus narrowing up the red stream. But still all the elements were in motion, nor did they become glued together, or permanently adherent or even cause an entire stoppage of the vessel. In the normal circulation the blood plates were never seen next the wall, and therefore they must all be carried along with the quickly-moving blood.

When the external violence was so great as to cause the current to slacken a little, there was an essential change in all of these relations. When the rate was such that the separate elements could just be distinguished in the middle, a blood plate was occasionally seen to be thrown out of the axial stream and appeared in the outer layer. If the rate became again accelerated, these plates were again drawn into the centre, and the old order was re-established.

On the other hand, if the current was slowed still more, the number of leucocytes lying against the wall decreased, being carried off by the stream, which however failed to bring others to supply their place, and passed through the walls. The number of blood plates steadily augmented, however, and soon assumed large proportions.

If the external violence was so great as to cause stagnation in the vascular territory, then all the elements of the blood, red and white corpuscles, and blood plates were indiscriminately mixed in the lumen of the vessel.

If a drop of blood as it comes from a vessel is examined with the microscope, the separate constituents show marked difference in their behavior to each other and to foreign bodies, slide and cover glass, with which they may come in contact. The red corpuscles do not stick either to each other or to the glass. They flow freely about in the capillary currents of the plasma, and arrange themselves in the well-known rouleau form. The blood plates, in consequence of

<sup>1</sup> Continued from page 465.

<sup>2</sup> See "U. und Schwanke Blutb.," Fortschritte der Medizin, Vol. 3, p.

some alteration in them adhere to each other and to the glass, while the leucocytes first become fixed to the glass and then begin to change their position by means of their pseudopodia. Direct or indirect insult to the vascular walls often called forth similar conditions of the elements of the blood within the vessels. The blood plates adhered, the leucocytes migrated, while the red corpuscles were freely suspended in the plasma.

One fact was often noticed in connection with attempts at local irritation or compression with a needle, and that was that a normal stream would keep on for hours at a place where this had been applied and where even a partial thrombus had been formed on the injured walls. But in all such cases it was noticed that the current was moving very rapidly and was separated from the obstruction by the plasma zone. When, however, the force was weakened at the same time that the local violence was applied, or had become diminished in a vessel with an injured wall, then the blood plates appeared in the liquid zone. And as soon as they came in contact with the obstruction, they adhered to it, and formed a thicker and thicker layer, until the lumen was here and there entirely blocked up.

As the results of their work, it may be stated that first they bring into prominence the fact, that in opposition to the generally received theory, a lesion of the vascular walls or the presence of an abnormal body is not alone sufficient to cause the formation of a thrombus. Disturbances in the circulation aid even more materially in producing this. When this has reached a point that the blood plates are hurled into the peripheral part, then an opportunity arises for them to undergo a typical alteration, for which the authors propose the name of "viscous change," and when this has come about, then thrombosis takes place. Where the stream has its greatest activity, there the normal condition is more easily preserved, but where its energy is small, as in the veins, or where, as in the smallest capillaries the axial stream entirely ceases, a coagulation of blood in the vessels can easily arise. The exact relation of the exudation of fibrin in this process is purposely left out, as well as a consideration whether in the later stages, there are any evidences of what is known as "coagulation necrosis."

Shortly expressed, the thrombus results from a disturbance of the mechanical relations of the blood stream and the viscous metamorphosis of the blood plates.

This theory is capable of explaining some phenomena which have hitherto been hard to understand. For example, the marantle thrombi win a solid foundation from the appreciable influence of a weakened heart's action. And those cases in which thrombi are not found in spite of marked alteration of the vascular walls, as in endarteritis, appear in another light.

#### ON EMBOLISM OF THE VEINS AND BACKWARD TRANSPORTATION IN THE VEINS AND LYMPH VESSELS.

A few cases have recently come under von Recklinghausen's<sup>3</sup> observation which could only be explained on the assumption that emboli had been carried along certain veins in a direction opposite to the normal direction of the current. That this could be produced experimentally has been known for a long time, but the cases which have hitherto been cited as examples, were in his opinion capable of another explanation.

Those which the author cites, are divided by him into two classes, one where the circulation was open, and the other where it has been closed.

The first case was one of myxosarcoma of the tibia with metastatic tumors and emboli of the pulmonary and renal veins.

The second was of acute cirrhosis of the liver, and pyæmia with multiple metastasis. Phlebitis of the veins of the pelvis of the kidney with retrograde transportation.

In the second category are those in which this backward carrying has taken place in a vein or lymph vessel after one of the chief branches has been permanently obstructed. This was illustrated by cases of cancer in the lungs in which the peripheral lymph canals on the surface were filled with the new growth.

The cases must be read in the original, as the value depends upon a very close following of the author's accurate observation on the arrangement and distribution of the embolic masses to which it is impossible to do justice in a summarized account.

He closes by saying that if he has called attention to a way, hitherto little recognized, in which metastasis can take place, he is still far from the idea that it plays a great part in their propagation. The long, well-recognized way, in the direction of the stream, must ever act as the chief path. But we must remain mindful of the fact that there are many possible ways in an organism as complicated as the animal body, and that our task is to take cognizance of this, and decide between them all, in a given case.

#### ON OLD THROMBI OF THE HEART.<sup>4</sup>

The subject is one that has been known for a long time, and many erroneous ideas have prevailed in regard to it. Laennec was the first to demonstrate the true nature of the so-called polyps of the heart, and through him and the older pathologists the distinction between the recently coagulated masses or false polypi and the older heart thrombi, or true polyps, was clearly brought out.

The form under which these latter appear, differ according to the time and place of their origin, and finally with their ætiology. Yet they can be divided into groups, which from their external appearance can be distinguished by four chief forms, naturally passing into each other.

(1) Small parietal thrombi, usually cystic in character, from softening of the central portion. (Vegetations globuleuses, Laennec.)

(2) Large thrombi often filling entire cavities of the heart, especially the auricular appendages or auricles.

(3) Pedunculated thrombi (heart polyps in the narrow use of the term.)

(4) Free thrombi, that is not attached to the wall and floating freely in the blood. (Ball thrombi.)

The first two forms are those most frequently met with, and the seat of the first is usually at the apex of the right ventricle, and having its starting point among the trabeculae. The centre of the globular variety is often occupied by a cavity, the result of retrograde metamorphosis. The second group are distinguished by their grayish or whitish yellow color, inflated structure, and often with a central softening. The chief seat is in the right auricle, then follows the left, then the right ventricle, and finally the left ventricle.

<sup>3</sup> Virchow's Archiv., Vol. 101, p. 502.

<sup>4</sup> Heitz, Deutsch. Archiv. f. Klin. Med., Vol. 7, p. 1.

They can extend from one cavity to the other, or into the large vessels. They come in a dilated heart, or in marantic persons.

The two last forms are much rarer, and the author contributes observations from the cases which have come under his notice.

The pedunculated ones are of considerable size, reaching at times the size of a hen's egg, and are solitary. Their seat of preference is the smooth surface of the interauricular septum.

Two cases of this sort are recorded. In one there was found a globular tumor attached by a short peduncle to the left side of auricular septum, midway between the fossa ovalis and the anterior segment of the mitral valve. When hanging down it almost reached the opening. The microscopic examination showed it to be composed of a loose fibrous tissue traversed by numerous thin-walled vessels. In the interstices of the tissue there were found clumps of golden brown pigment mixed with a finely granular detritus. The endothelium covering the auricle was not continuous over the surface, and this confirms the idea that this is to be regarded as an organized thrombus, and not an outgrowth from the wall.

In the second case, a tumor the size of a nut was found attached to the posterior edge of the entrance into the left auricular appendix by a stem the size of a knitting-needle, and was freely movable in all directions. The histological examination showed a structure essentially the same as in the last, only the organization was not quite so complete.

In looking through the literature of the subject, only nine other cases were found recorded. They differed from these in the mention of a lamellated structure and central softening, and sometimes calcification. In one only was the seat within the ventricle, in all others in the auricle, preferably the left, near the foramen ovale. The only cause that is assigned for this position is that a quiet eddy in the blood current may occur here.

The fourth variety of free swimming thrombi in the heart, is of exceedingly rare occurrence. Of this form he had met with two cases.

The first occurred in a man twenty-two years old, who as a child had suffered from rheumatism. He entered the hospital for sloughing of the lower leg, and died suddenly.

The markedly enlarged left auricle was found to contain two thrombus masses. The one somewhat ball-shaped with one part of the surface irregularly marked, rested loosely in the appendix, while the second, perfectly round and nearly as large as a potato, was perfectly free in the cavity of the auricle. The edges of the mitral valve were so adherent as to reduce the opening to an irregular, narrow funnel. The corde tendineae were shortened and the papillary muscles thickened.

The loose thrombus, the surface of which looked as if it had been turned and polished in a lathe, lay like a ball valve in the opening. The centre was occupied by a cavity filled with broken-down material. A second polished thrombus was found in the left ventricle, evidently having originated in the auricle.

The second case was in a woman, thirty-nine years old, a maniac, who had suffered for years with symptoms of mitral stenosis and insufficiency, and who died suddenly.

On removing the heart a round thrombus rolled

out of the left auricle. It measured four centimeters and had a firm elastic covering of coagulated fibrin, and gave a distinct wave of fluctuation. The heart was enlarged in all its dimensions, but especially the right ventricle. The mitral was very much contracted.

One other case only has been found recorded. It was that of a convalescent patient who died suddenly. In the heart there was a very firm, almost cartilaginous, grayish yellow, freely movable coagulum of half the size of a walnut, lying over the opening of the mitral valve.

The seat of origin of such thrombi is to be regarded as in the auricular appendage, from whence they become detached, and being too large to pass through the mitral valve, become rounded and polished by the to-and-fro movement in the blood.

#### INVESTIGATIONS ON THE PNEUMONIA FOLLOWING SECTION OF THE VAGUS NERVE.

From the time of Valsalva it has been known that if the vagus nerve was divided, a form of pneumonia was subsequently developed. Traube was the first who rightly characterized it as a broncho-pneumonia, caused by the fluid from the mouth finding its way into the lungs, as a result of the paralysis of the larynx and oesophagus. Schiff has opposed to this the idea that it was due to paralysis of the vaso-motor nerves of the lungs. It is, however, generally conceded now that Traube's theory is the right one.

Starting from this point, Lehau<sup>6</sup> has endeavored to determine what are the harmful agents in the fluid which bring this about. And he has naturally turned his attention to the microorganisms.

With this end in view, a series of seven rabbits were first used. A piece of the vagus was excised in each case under antiseptic precautions, and the animals kept fasting, and if they did not die sooner, were killed at the end of twenty-four hours. Scrapings from the cut surface of the lungs were dried upon the cover-glass, and was also sown in nutrient gelatine. When examined microscopically, both the slides and the pure culture showed an elliptical coccus of medium size, often united in pairs, and more rarely in strings of three or four. A formation of spores was not observed. It seen in a drop of fluid they gave evidence of a lively movement.

On the gelatine plate cultures, at the ordinary temperature, the colonies appeared as round, darkly granular groups with slightly rough surfaces and edges. After twenty to twenty-four hours there is seen with a low power a little liquified spot at the centre of each colony, which has a whirling motion. In a short time the gelatine is entirely liquified. When the cultivation is carried on in a breaker glass, a white sediment is deposited after the nutritive material has been rendered fluid. This organism also grows in blood serum, in bouillon and on potatoes, over the surface of which it soon spreads.

With the pure cultures thus obtained, injections were made into the trachea, and also used for atomized inhalation and finally for direct introduction through the thorax wall into the lung. In all of these a pneumonia, similar to that following section of the vagus, was produced in the majority of cases; except where the culture had been sterilized before use by heating, and there it was without any effect.

From these experiments the author concludes that

<sup>6</sup> Fortschritte der Medicin. Vol. 3, p. 483.

it is this bacteria which causes the disease. He endeavored to isolate it directly from the fluids of the mouth, but was only successful in finding it once in twenty-five cases.

Another interesting point in his investigations was the finding of two other microorganisms in the lungs and in the blood in great quantities; but which he considers as perfectly innocuous. He tried injecting large numbers into the trachea, but failed to produce any or only very slight inflammation in the lungs.

The one was a round micrococcus, somewhat above the medium size which grew on gelatine, without liquifying it, in the form of white colonies only raised a little above the surface.

The second was a moving elliptical coccus, similar in appearance to the pathogenic one, but which reduced the gelatine fluid less quickly and the colonies of which were not so darkly granular.

The above facts are of importance, as it is here clearly shown that the very abundant presence of bacteria in connection with a pathological process is far from a proof of their causal relation. These must be regarded as having developed secondarily to the pneumonia, and have thence entered the blood, while the disease was excited by another which remained in the lungs.

#### EPITHELIOMA IN A PHTHISICAL CAVITY.

The following rare case is reported by Friedlander:—<sup>6</sup>

A man died who clinically presented the features of phthisis with pleurisy on the left side.

Upon opening the lungs there was found in one of the cavities at the apex of the left a tumor attached to the walls by a broad base. From this point it tapered to a sort of pedicle, which lay in the bronchus connecting with the cavity, and enlarged again to a rounded end the size of a joint of the finger. This nearly filled the lumen of the branch in which it was, but yet was freely movable.

The pearly gray medullary aspect of the growth suggested at once the diagnosis of cancer, and the microscope showed it to be a true epithelioma. The stroma was everywhere firm, and only moderately vascular, and infiltrated in only a slight degree with round cells. In the meshes formed by this were imbedded anastomosing cords of cells, of varying breadth. The cells within these were mostly polygonal, with serrated edges and surfaces. Here and there they were scale-like, without nuclei, reacting like the horny layer of the skin, and imbricated like an onion. In short, the typical picture which is found in epithelioma of the lip, tongue, œsophagus, etc.

Nowhere else in the body was anything found which could stand in the light of a primary or secondary growth to this.

Therefore this must be regarded as the unusual occurrence of an epithelial tumor proceeding from an ulcerating tuberculous surface. It seems almost at first sight as if this could not be explained in accordance with the generally accepted theory, which supposes that such growths can only start from pre-existing epithelium. But the author recalls an observation of Griffini, who found in defects of the trachea and bronchi, especially those caused by tuberculous ulceration, that a layer of stratified pavement epithelium had been developed there. And Ziegler has also

noticed flat epithelium on the edges of syphilitic ulcers of the air passages.

On the wall itself of a cavity, so far as is known, epithelium has not been found, but this is not impossible, and it might be supposed to creep in from that lining the bronchus and become modified.

In subacute and chronic bronchitis (with the development of granulation tissue in and about the bronchial walls) Friedlander himself has noticed an atypical growth of the cells of the living coat by which buds and tongue-like processes of epithelium were found in the bronchial wall and its surrounding. These have the closest resemblance to cancer, but that they should ever form a true new growth must be a very rare occurrence.

### Reports of Societies.

#### BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

E. M. BUCKINGHAM, M.D., SECRETARY.

OCTOBER 26th, 1885, the President, Dr. F. W. DRAVER, in the Chair.

#### SEVERE AND PROLONGED NEPHRITIC COLIC WITH RECOVERY.<sup>1</sup>

DR. F. GORDON MORRILL read a paper with the above title, for the discussion of which see below.

DR. F. S. WATSON reported a case of  
URETHRAL CALCULUS.

H. C., six years ago, had gonorrhea, which ran a normal course, and has since resulted in no harm. One year ago he had two attacks of renal colic, six months ago another, and two months ago he began to have pain in the end of the penis after micturition. Three days since he had another severe attack of renal colic, which was followed by complete retention of urine due to the passage of a stone into the urethra, but by manipulating the stone, he was enabled to urinate beside it slowly. The patient came to the clinic on July 1st, with a stone to be felt about one inch behind the meatus. Attempts at extraction without ether were so painful that the patient fainted and became pulseless. Upon being restored, he was etherized, the meatus was incised and the stone readily extracted. It was seen to be of the size of a large pea, oblong in shape, rough, and having a nucleus of uric acid, with a coating of phosphates. Its largest diameter was twenty-eight millimetres. The patient remained one day in the house, and then went home without any untoward symptom having made its appearance. This specimen is chiefly of interest on account of its being of a rather large size to pass spontaneously through the urethra.

Dr. F. S. Watson reported as follows a case of

#### STONE IN THE BLADDER, CRUSHED AND EVACUATED BY BIGELOW'S METHOD, UNDER THE USE OF COCAINE.

These fragments of a soft phosphatic stone weighing sixty-nine grains are from a patient aged sixty-two. There was no special interest attaching to the stone itself, except that the operation (the ordinary one of Professor Bigelow) was performed without any other anæsthetic than cocaine, on which account he thought it worth reporting. Cocaine in a four per cent. solution was employed in the following way: a syringe full of

<sup>6</sup> Fortschritte der Medicin, Vol. 3, p. 207.

<sup>1</sup> See page 506.

it was injected into the urethra, by means of an Ulzmann syringe, and allowed to remain for two or three minutes. The bladder was then emptied, and an ounce of the same solution injected through the catheter. After waiting for three minutes, the smaller-sized Bigelow lithotrite was introduced, and the stone easily caught and crushed, the time occupied being about fifteen minutes. The patient complained of an occasional twinge of pain, especially toward the end of the time, but was, on the whole, almost free from suffering. During the work with the evacuator it was found necessary to stop once and withdraw it, on account of pain and vesical tenesmus, which, however, passed off after a second application of cocaine, so that the rest of the work could be readily accomplished. The patient expressed himself as well pleased with the effect of the drug, and of its having enabled him to escape the unpleasantness of etherization.

Dr. Watson also read a paper on a case of

STRUCTURE OF BOTH KIDNEYS. DOUBLE HYDRO-NEPHROSIS. LEFT LUMBAR NEPHROTOMY. DEATH IN FORTY-EIGHT HOURS. AUTOPSY BY DR. GANNETT.<sup>2</sup>

The President said that as the papers were upon kindred subjects, he proposed to have them discussed together, and he called upon Dr. Francis Minot to open the debate.

Dr. MINOT said Dr. Morrill's case was of interest with reference to the diagnosis of calculus in women, neuralgia of the abdomen sometimes so closely resembling it with them, as to make diagnosis at the beginning of an attack not merely hard, but for a time, impossible. He had had two such cases, both in women who had inherited a markedly nervous temperament. In both, there was irritable bladder and a somewhat restricted flow of urine for a time. In neither was there any tenderness, nor was he able to give relief with any amount of morphia that he dared to use. In both, however, two or three eight-grain doses of quinine seemed to so cut short the pain, that he could not help believing it was quinine, and not the passage of a stone, that ended it.

Dr. C. B. PORTER said that having come in late, he had not heard the papers, and was, therefore, not criticizing the treatment of the readers, but that personally, he objected to the use of large doses of morphia in these cases. Sudden cessation of pain by the passing of a stone, may be followed by poisoning. He had seen marked opium narcosis under such circumstances, and believed that ether was much safer. The spasm of the muscular coat of the ureter is more easily relaxed by ether than by opium, and that is another reason for preferring its use.

Dr. O. W. DORR referred to a case which had been under his care for three weeks past, and which had presented many symptoms similar to those he had observed in the case reported by Dr. Watson before he called him in to operate.

The lady was twenty-six years of age, three months advanced in her second pregnancy. During the past year, he had six previous attacks of severe pain in the left lumbar region, coming on very suddenly and continuing until relieved either by morphia or ether. She was usually up and about again in two or three days. The present attack began on the morning of October 7th, and was relieved by morphia in about six

hours. Late in the afternoon, it returned suddenly with "ten-fold severity," and the patient was kept under ether for some hours. The following morning, there was very great sensitiveness throughout the left lumbar region, and especially marked along the course of the ureter. On the 9th, the tenderness had become so acute that she could hardly bear the gentlest examination, and at this time was noticed an unnatural fullness above Poupart's ligament, which became decidedly pronounced toward evening. During the day, she had passed only a few ounces of urine, and no stone had been discovered. The following night, the distension became more noticeable, and symptoms of general peritonitis ensued. He remained with her throughout the night and kept her partially narcotized. Hot fomentations were applied continually. At noon of the 10th, the distension suddenly subsided, and the urine became very free, requiring the frequent use of the catheter, but no stone was detected.

From that time until the present, there has been marked resistance felt in the left lumbar region, with dullness on percussion, which has steadily diminished, as has also the tenderness, which now is scarcely noticeable, excepting when the patient attempts to sit up, or when she has a movement of the bowels. At these times, she is conscious of a "deep-seated sore spot" about the size of a pear, which can be felt also externally.

Dr. EDGS and Dr. PORTER had seen the case in consultation and agreed with him that it was a case of circumscribed peritonitis, with considerable effusion of lymph following the passage of a renal calculus. The treatment now is simply rest in bed, with hot applications externally.

Dr. A. T. CABOT was reminded of two cases of obstructed ureter that had been already published. A boy of ten fell down stairs, getting generally shaken up. He afterward passed bloody urine and had a swelling in the side, from near the ribs of the right side to the crest of the ileum. This was aspirated by Dr. Langmaid at the Children's Hospital, getting no urine, but a fluid which contained urea. This afterward reaccumulated, and Dr. Cabot having taken the service, operated as Dr. Watson had done, getting from one and a half to two pints of fluid, with much urea. The patient got well with antiseptic dressings. The speaker believed that the ureter had acted as the urethra sometimes does in similar circumstances, a full bladder aggravating a stricture, and puncture of the bladder making it passable again.

Dr. Cabot also spoke of a case of obstructive hydro-nephrosis with mobility of the kidney, in a woman of twenty-five or twenty-eight. There was pain in the right side, and a swelling as large as a fetal head. He had aspirated as a preliminary, getting urine containing pus, and had then made an opening in the loin, first stitching the sac to the skin. The pain was relieved and the wound healed, leaving a sinus admitting a probe a fraction of an inch, which did not heal; perhaps owing to neglect of cleanliness on the part of the patient. It is proposed in England to perform nephrotomy as a preliminary to nephrectomy in such cases.

Dr. R. T. EDGS agrees with Dr. PORTER as to the danger of large doses of morphia, but also thinks that anesthetics are not without their risk, and mentions a case in which a patient, with a large uric acid calculus took pounds of chloroform, and got into a condition

resembling delirium tremens, which did not go off when the stone passed and the chloroform was removed.

DR. J. C. WARREN had had a similar experience with ether in a patient who had no large calculus, but who had kidney colic, with urine highly charged with urates. He had had some attacks, and always begins with ether. In his case, excitement grows to delirium, and he now gives ether in the beginning, and secures a night's rest with opium, giving ether again afterwards.

DR. PORTER did not mean that he never gave opium. On the contrary, he does give it in small doses in connection with ether.

DR. MORRILL said that in his case it would have been hardly practicable to give ether for three months.

DR. W. W. GANNETT, before describing the results of the autopsy in the case of double hydronephrosis, gave a brief summary of the usual conditions found in cases presenting a clinical history like that of Dr. Watson's. Earlier in the life of the individual, associated with symptoms of renal colic, a calculus lodges in some portion of one of the ureters, causing obstruction, leading to a collection of the urine behind the stone, increase of pressure in the pelvis of the kidney, and upon the renal substance itself, with suppression of all secretion, and finally, a hydronephrosis. A compensatory hypertrophy of the other kidney now occurring, the patient suffers no inconvenience. If a calculus forms in the sound kidney and blocks its ureter, anuria occurs. Here again, the back pressure in the pelvis soon increases to such a degree that no more urine can be secreted, and the patient dies uræmic, no time being afforded for dilatation of the pelvis and ureter above the obstruction. No hydronephrosis occurs, the kidney showing simply evidence of having an increased amount of blood in the vessels. The present case showed appearances differing markedly from the above.

DR. E. N. WHITTIER read a report by Dr. Charles W. Townsend, of a case of

#### PERSISTENT HIGH TEMPERATURE IN TUBERCULOSIS, WITH TUBERCULAR PHARYNGITIS.

Which occurring with abdominal symptoms, might mislead to a diagnosis of typhoid. The case will be published in a subsequent number of the JOURNAL.

DR. R. H. FITZ showed the specimen of tubercular pharyngitis from Dr. Townsend's case of tuberculosis, which he thought might be of special interest in connection with the recent report by Dr. De Blois of a number of cases of this comparatively rare lesion.

(Dr. Fitz's description will be published with the report of the case.)

The lateral walls of the pharynx contained extensive patches of minute, isolated, and agglomerated gray and yellow granules, without ulceration. The base of the tongue and region of the left tonsil (the right not having been removed), were the seat of an extensive ulcer with indurated base, in which were numerous cheesy granules. The surface was rough, irregularly reddened, opaque yellow in patches, and occasional shreds of mucous membrane were attached. Isolated gray tubercles were seen beyond and near its margin. There was an extensive acute miliary tuberculosis of the lungs, spleen, and peritoneum, a moderate miliary tuberculosis of the liver. A limited chronic miliary tuberculosis of the lungs was associated with extensive chronic tubercular ulcers of the ileum and colon.

Near the apex of the left lung was found a cheesy bronchitis with bronchiectasis.

DR. E. H. BRADFORD showed a specimen of

#### TUBERCULOSIS OF THE JOINT,

described, by Volkmann. In this case it was the hip joint that was excised, and the specimen was a good one of tuberculosis of bone.

#### PHILADELPHIA PATHOLOGICAL SOCIETY.

W. E. HUGHES, M.D., RECORDER.

MEETING October 22d, 1885.

The President, J. C. WILSON, M.D., in the chair.

DR. J. COLLINS WARREN read a paper on

#### A COMPARISON OF THE CHANGES IN ARTERIES AFTER LIGATURE AND IN THE DUCTS ARTERIOSUS AND UMBILICAL ARTERIES AFTER BIRTH.

After the ligature of an artery in continuity the earliest changes noted are the formation of the thrombi within the vessel and the development of a mass of inflammatory tissue or callus around the point of ligature externally. No perceptible cell action can be observed in the inner wall with low powers during the first week, although under favorable circumstances a proliferation to a limited extent of the endothelial cells near the point of ligature can be seen with high powers, and occasionally a few wandering cells may be found to have penetrated the walls of the vessel at the same point. In the second week the bundle of fibres of the adventitia, which were surrounded and held by the knot, have been absorbed and the two ends of the vessel retract slightly from one another, leaving the ligature imbedded in and partly disintegrated by the granulation cells. The walls of each portion appear to form a complete end-sac, and it looks at this time as if the healing process were complete, but it can hardly be said to have more than begun, as the vessel has not yet passed through what may be considered as the first stage of healing. The beginning of the second stage is marked by an unfolding of the ends of the vessel, the walls separating somewhat after the manner of opening of a bud, which permits the entrance of a considerable quantity of the granulation tissue. A disintegration of the thrombus follows, and we have now a fully developed external and internal callus, a small fragment of clot still protecting the latter from the current. The ligature may be totally disintegrated and absorbed, or it may have become encysted, or finally it may have created a small abscess about itself which has discharged the fragments of thread through a sinus opening externally. The second stage is completed when the internal growth has reached the neighborhood of a branch. After this we have an absorption of the callus which, as in fracture, is only a provisional structure, and eventually the two ends of the vessel are tamed held together by a slender cord of varying length. The walls of the vessel are slightly separated at each end by a cicatrix consisting of connective tissue externally, inside of which is another layer consisting largely of unstriated muscular fibres, the surface being covered within by a new endothelium. The cicatrix is always pierced by a vessel which terminates in a number of capillaries ramifying in the cord. We have here a

scar made up of three layers resembling closely the three coats of the vessel.

In the large vessel of amputation stumps we have a somewhat different series of changes. Soon after the ligation the end of the vessel may be seen imbedded in granulation tissue and containing a thrombus of varying length. By the second week there is a marked change in the intima extending for some distance above the point of ligation, probably to the first large branch or to the origin of the vessel. Examined several months later when the healing process has been completed, the vessel is found to be preserved in the form of a cord running from the first large-sized branch to the cicatrix of the stump; on laying open this cord, the walls of the vessel are found preserved, the interior being filled with new tissue, leaving spaces occupied by one or more vessels. There has been a process resembling that known as obliterating endocarditis by which the calibre of the blood channel has been narrowed to an extent to adapt it to the diminished blood supply. In this obliterating tissue we find comparatively large vessels with new coats consisting of an endothelium, an elastic membrane, and also a new media. An erosion preparation would best represent the condition of the arteries of the stump at this time. The main artery would, after giving off its largest branches, break into a spray of smaller vessels, no one of which would predominate.

A comparison of these two modes of healing with the changes seen in the arterial system soon after birth shows certain resemblances in the two processes. The ductus arteriosus about the time of birth differs considerably from the structure of the aorta and pulmonary artery. The media is much thicker than in either of these vessels; it is thrown into irregular folds which are increased at the time of birth, and help to narrow its calibre. The distinctions between the different layers of its walls are less marked than in other vessels. The lamina elastica is indistinct and in places apparently wanting; the media consists chiefly of longitudinal layers of muscular fibres, a few circular bundles existing in the innermost layer. A few weeks after birth a greater portion of the walls of the ductus undergoes hyaline degeneration, the inner or circular fibres of the media alone remaining, these being reinforced apparently by a growth from the media of the larger vessels. At this time there is an active growth of long spindle-shaped cells with staff-shaped nuclei at the edges of the media bordering on the opening into the aorta; here is also a moderate thickening of the intima. Eventually the hyaline tissue becomes absorbed, and is replaced by a ligamentous band of fibres which becomes continuous at either end with the media of the larger vessels. At the aortic end in a longitudinal section we see the media slightly separated. At the point of the cicatrix and between them, and also continuous with them are the longitudinal fibres of the ligamentum arteriosum. In this ligamentous tissue and between the edges of the media are numerous new muscular cells; nearer the surface is a layer of thickened intima, which in the aorta has not only connective tissue in it, but also a deep musculo-elastic layer; in the centre of the depression marking one side of the cicatrix, a small vessel is given off, which penetrates into the axis of the ligament where it either loses itself in a capillary network or becomes continuous with a similar vessel coming from the pulmonary artery. We have here conditions closely resembling those

which have been described as existing in the cicatrix of a large artery after ligation in continuity, namely: the slightly separated ends of the media between which lie the fibres of the ligament connecting it with the pulmonary artery, a new intima and a new growth of muscular cells, and finally a central arteriole. The only point of difference is the preservation of a layer of circular muscular fibres which form an outer wall to the ligamentous band, a much needed support at a point exposed to great tension. Further protection is afforded by the oblique insertion of the ductus into the aorta, diminishing the pressure upon this particular point. As with the umbilical artery, or that usually called the hypogastric artery, the portion within the abdomen at its origin from the internal iliac is a vessel of considerable size, being in fact a continuation of that artery. At its termination in the umbilical wound it has greatly contracted and is filled with clot for a distance of about one inch. The outlines of the various walls are not as distinct as in other vessels and the elastic lamina for the most part wanting. No special change is seen in the elements of the walls of the vessel, except a slight accumulation of endothelial cells near the apex of the thrombus.

A few weeks later there is a distinct growth on the inner surface of the wall up to its point of origin, the terminal portion having undergone a hyaline degeneration and obliteration for a short distance. The vessel has greatly contracted throughout its entire length, and its calibre is further diminished by the growth in its interior. Cross sections taken from the superior vesical artery in adult life, show the media as a wall thick out of all proportion to the size of the vessel, and consisting not only of its original wall, containing longitudinal muscular cells interspersed with elastic tissue, but also an inner circular row of cells which is provided with a well-formed elastic lamina. It seems probable that the greater portion of the hypogastric artery has been preserved, the ligamentous band which extends to the umbilicus consisting of the obliterated extremity of that vessel much elongated during the process of growth. The series of changes which occur in the hypogastric artery after birth is closely analogous to that seen in the main trunk of an amputation stump—a slight portion of each vessel is destroyed, both retracted and are attached to the terminal cicatrix by a band of fibrous tissue, both remain as previous vessels with thickened coats and narrowed calibre. In both, the process is not unlike that seen in the so-called obliterating or compensatory arteritis. Arteritis hardly seems a term applicable to the changes taking place in normal arteries after birth, nor can the alterations which have been developed through the whole length of a large vessel, extending a considerable distance from the original seat of inflammation, be strictly regarded as of an inflammatory nature. May not the obliterating growths found to exist simultaneously in terminal arteries in widely removed portions of the body of the same individual also be regarded not as of inflammatory nature, but rather as a secondary and formative process, closely connected with disturbances in the mechanism of nutrition, designed to adapt the vessels to a diminished blood-supply?

Dr. S. W. Gross said, in view of the fact that Dr. Warren's teaching seemed so directly opposed to that of other observers, he would like to have some points cleared up. He would, therefore, ask if Dr. Warren held, first, that instead of the external cord where it is

included in the ligature sloughing and coming away with the ligature, the pressure of the ligature sets up an irritation which causes the adventitia to return to its embryonic state with a reconversion, after the ligature has cut through this, to connective tissue, and, second, whether the repair of arteries was brought about by the ingrowth of the cicatricial tissue, which he likened to provisional callus, together with some proliferation of the muscular cells of the media.

DR. RANDALL said, that as the result of careful study of the subject he had always found the clot present at first, and that it was honey-combed even in the first few days by the contraction of its fibrin, through the spaces thus formed the blood seemed to be circulating. Cells, either original white cells, or of endothelial origin, occupied the walls of these cavernous spaces and seemed to sheathe them. The red cells early melted down into a homogeneous mass furnishing the frame-work upon which the reparative tissue was built. The "plastic clot" of some observers he had not seen, the new cells being distributed throughout the old clot as well as upon the vessel walls and not specially collected in the immediate neighborhood of the ligature. The obliteration of the vessel was accomplished by the growth and contraction of the trabeculae of new tissue built upon the remains of the original blood clot. Even close to the ligature he had not found the vessel walls greatly altered, merely showing a great increase in the nuclei and in the number and size of the vasa vasorum, the lamina elastica being distinct and, as a rule, intact. Toward the end of the first month the new tissue was largely spindle-cells but careful staining had given no suggestion of muscular tissue. But, not having carried his study beyond the first month he had no data upon this subject, since the development of muscular tissue is claimed to occur only at a later stage.

DR. FORMAD was inclined to favor the views of Dr. Randall. The observation of Dr. Warren that the new-formed connective tissue played the most important part was to him entirely novel. He thought probably that pressure upon the artery from without, with consequent diminution in its lumen, might bring about a condition more analogous to the growth of fetal life than to inflammation.

DR. MEARS remarked, we are liable to be confused in considering this subject by the presence of the blood in the vessel. So far as the process of healing after ligature is concerned, we may consider only the structures which enter into the formation of the vessel wall, which is complex in character and composed of connective tissue, elastic and endothelial tissues. Dr. Warren has given us a very clear demonstration of cicatrization as it occurs in these structures after application of the ligature.

DR. TYSON said the most novel feature to him in Dr. Warren's observations, was the part played by the muscular tissue. This apparent increase in the muscular tissue, he was inclined to believe, was really only a proliferation of intermuscular connective tissue. He was becoming more and more convinced that there was only one kind of inflammation — the interstitial. He feared that he might himself mistake a proliferating connective tissue with spindle cells for muscular tissue. It is true that new formed capillaries and arterioles have muscular walls, but the development of these seemed to him to be a slower process. He had expected to find a process of repair in the ductus arte-

rius different from that in an ordinary artery. This process he had expected would be a true endarteritis, for it seems that the conditions of closure here are rather different from those in the ligaturing of an ordinary artery, and in the umbilical artery, where we have also ligature practised.

DR. WARREN, in closing, said, in cases where there is much breaking down and little repair, there might be a sloughing of the external coat, yet in his experiments this part of the arterial wall did not slough, but was simply absorbed by the granulation tissue, as is the ligature itself in some cases. In the normal condition even the elastic lamina is not a perfectly continuous plate: he did not refer to these breaks, however, but to numbers of little ruptures incident to the pulling out of the wound of the artery in the act of ligature; however, this need not necessarily occur. He had not attempted to identify anything like muscular tissue early; this could not be recognized till we had a permanent cicatrix formed. He had carefully eliminated all sources of error, and it seemed to him that in almost all cases there was a considerable number of these muscular cells. The layer was not always as well marked as in his diagram; especially was this true of human cases, but these had all been in alcohol for some years; of the fresh specimens he had selected only those in which he had considered the process complete. In a specimen which he had here to-night, through an opening in the lamina elastica cells could be traced from the muscular layer, those in the inside resembling exactly those outside. These facts, together with the fact that we have normally a few muscular cells inside of the lamina elastica, lead him to believe in the proliferation of the muscular tissue. The disintegration of the blood clot is accomplished by granulations growing inward from the callus, there being two sets of blood vessels, one in the granulations, the other (blood spaces rather) in the clot itself; these unite about the end of the first or second month.

#### NEW YORK STATE MEDICAL ASSOCIATION.

SECOND annual meeting, held in the hall of the Murray Hill Hotel, New York, November 17, 18, 19, and 20, 1885.

##### FIRST DAY. — MORNING SESSION.

The Association was called to order at 9.30 A.M., by the President, DR. JOHN P. GRAY, of Utica.

The committee of arrangements reported that there were forty-nine scientific contributions, four addresses, and several contributions to the study of pneumonia, to be presented before the Society. The number of papers presented last year was fifty.

In the report of the council it was recommended that papers which were to appear in the volume of transactions of the Association be not published in the medical journals previously.

The treasurer's report showed total receipts for the year to be \$2,464; balance in treasury from last year \$683. Deducting disbursements for the year there remained a balance of \$423 for the library fund. The surplus from anniversary subscriptions last year was \$630, \$345 of which was placed to the account of the building fund. Excluding disbursements there remained in the library fund \$34; \$80 had been subscribed for a binding fund.

DR. FERGUSON offered some amendments to the by-laws to be acted upon at the next annual meeting. They referred chiefly to the abolition of the office of corresponding and statistical secretary, the appointment of a librarian by the council, and striking out certain words as to the qualifications of those becoming members.

#### RELATIONS OF THE STATE TO MEDICAL SCIENCE.

The President, DR. JOHN P. GRAY, then read his address on this subject. He reviewed the educational policy of the State of New York, which was confined principally to supervision of the common schools and of the normal schools in which teachers for the common schools were trained. The duty of the Board of Regents were briefly referred to. Law schools, medical schools, scientific schools, etc., were corporations sustained by private contributions or earnings, and were individual enterprises, receiving no grants from the State. He then asked the question, what was proper legislative interference with this class of institutions which represented scientific education and research? That the State itself should undertake such education as a public measure and for public policy constituted a serious question in political economy, and for this State, for the present at least, that question has been answered adversely. Legislative control over the medical schools of this State was not demanded by public interest. It was not intended to dispute the power of the Legislature to regulate medical education and declare what will constitute a doctor in medicine; but the fact was that the Legislature exercised its power only in the way of fostering, protecting, and advancing the interests of medical science up to giving the best opportunities to schools for attaining this end, and at the same time as far as possible, allowing the individual entire freedom of special study, and of the means for acquiring knowledge of medical science. The State had not adopted any particular school or system of medicine as against others, and could not do so. It was the part of wisdom to give the widest latitude to discussion wherever matters of opinion seemed to be in conflict. The giving to the physician certain powers which the State had conferred upon him, was the highest endorsement which the State could give the profession. The State had left the culture and development of medical science to the medical profession alone, had granted the right to incorporate societies and associations in order to maintain its unity of work, and for its elevation and progress.

With regard to the services of the medical profession to the public, little need be said. The physician's services were sought by the people in the same way that the services of the lawyer or other member of the community were sought.

The author then came to the matter of granting diploma, and the control of this power by the State. His views were adverse to any such proposed change. The State did even attempt to regulate the compounding and sale of drugs and nostrums. As the State had nothing to do with the teaching in the schools, so it should have nothing to do with the examinations. What possible efficiency such a proposed board of examiners could have in benefiting medical science, the profession and the people, did not appear. Such a change would transfer students who come to the medical college of New York from all over the country,

and from foreign countries, to the schools of Boston, Philadelphia, etc. The schools had done excellent work in elevating the standard of medical study, and while there was room for further improvement, to seek it in the guardianship of the State was an error. It was true, also, that preliminary education should be better, and this demand also promised to be met as soon as the advance of the times would permit.

The reports of the different branches of the State Association were then read, in which it appeared that a large number of papers on different subjects connected with medical science had been read, and other work had been performed.

The president of the New York County Medical Association, DR. C. A. LEALE, also read the report of the annual labors of that Society.

#### ADDRESS IN STATE MEDICINE.

DR. ALFRED L. CARROLL, president of the Section in State medicine, then read his address.

The author reviewed briefly State medicine, or sanitary medicine, as it existed in ancient times, and said that many excellent rules existed among the Israelites which would be of practical utility in sanitary matters if adopted at present. State medicine in its comprehensive sense included all the medical interests of the State. But in popular estimation the term had a narrow significance; was applied more especially to practical administration of sanitary science for the protection of public health. Even with this limited definition, preventive medicine had presented its claims with greater vigor than other specialties. Modern sanitation might be defined as applied physiology. The sanitarian should be primarily an accomplished physician. But he should superadd to his medical knowledge some theoretical, if not practical knowledge of architecture and engineering. He should know how to detect defects therein, and suggested remedies to be carried out by the artisan. Dr. Carroll then pointed out some of the conflicting opinions of sanitary men regarding what constituted sanitary conditions. The superstructure of public sanitation had to be built upon the laws of personal hygiene. It followed that enlightenment in this direction must originate with physicians. As was the seed sown by medical schools, so would be the harvest of public health. How have these schools fulfilled this condition? The author said he would grant that many of them furnished the opportunities for a pupil having means and ambition to make use of them to gain the necessary education. But what was needed was an enforced education in all important branches, not leaving their study optional with the student. The author named the studies and time required for study in force in England, and said that while the work seemed formidable, it would also be seen that the knowledge to be acquired was not more than every physician should have when he comes to discharge his duties to the public and to private patients. In his official relations, Dr. Carroll had had opportunity to learn what were the acquirements of persons who sought positions on boards of health, and the answers by men graduated from regular medical schools were often absurdly erroneous. Now and then there were marked exceptions, even in remote country districts.

He thought a weakness in the State and local boards of New York existed in the short term of office, and time spent in inducting new men into strange

duties. A preliminary education and a higher and more thoroughly enforced medical education were pointed out.

#### FIRST DAY, AFTERNOON SESSION.

The President in the Chair.

#### TUBERCULAR CONSUMPTION: IS IT EVER HEREDITARY?

DR. HENRY D. DIDAMA read a paper on this subject, in which he quoted the opinions of different authorities on the subject of a hereditary tendency, hereditary diathesis, etc., and also the results of post-mortem examinations by various pathologists, and said that in the examinations of the bodies of hundreds and thousands of fetuses, none were found to have tubercle, which weighed very heavily against the hereditary theory. He also quoted the statistics furnished by insurance companies, in which it appeared that the majority of cases of phthisis occurred in persons whose parents had not suffered from the disease.

The following were the conclusions which the author reached:

*First.* That tuberculous disease is not inherited.

*Second.* That if a special tendency to the disease be transmitted, the term liability better expressed the idea than the term tendency.

*Third.* Many conditions, as poor and insufficient food, damp and impure air, stunted sunlight, and certain occupations, favored the development of the disease.

*Fourth.* Two conditions are almost indispensable — abundance of bacilli and an inviting asylum for their development, whether it be an inherited or an acquired virulence.

An important indication was to place the newly born of a phthisical mother under the charge of a healthy wet nurse, who should occupy a room entirely secluded from that of the consumptive members of the family. This gave an opportunity to strengthen the feeble constitution and to eradicate a liability to the development of consumption. If a syphilitic taint existed or was suspected, the author advised anti-syphilitic treatment not only with a view to cure the syphilis, but also with a view to strengthen the constitution and guard against the development of phthisis.

DR. ROCHESTER said that some years ago he made an autopsy on an infant which died three weeks old, and found one lung crammed with miliary tubercles, and in the other was a cavity the size of a hickory nut. The mother was healthy. The father had died before the baby was born. In another case in which the father died before the birth of the child, and the mother was a healthy woman, having no tuberculosis, the child died at eighteen months of age, having had for a long time before death, every indication of pulmonary phthisis, and recently, of tuberculosis of the vertebrae. The father in both cases had died of consumption before the birth of the child. In the light of these cases, he could not help believing that sometimes, at least, phthisis was hereditary. He would admit, however, that many people have phthisis whose parents were free from the disease. The paper was further discussed by Drs. Colvin, Pomeroy, and others.

#### PSOITIS AND PERISPOITIS: THEIR PATHOLOGY AND DIFFERENTIAL DIAGNOSIS.

DR. SIMON TUCKER CLARK, of Niagara County, read a paper with this title, in which he first referred to the paucity of the literature of the subject, and the difficulties attending a differential diagnosis, and then

proceeded to give the clinical histories of three cases which had come under his personal observation. In all of the three cases there was a history of traumatism. In the first case, the patient, a woman without children, aged forty-three, had received a blow on the abdomen, which was followed by severe pain in the supra-pubic region, two inches from the median line. A hard lump from which the pain seemed to proceed, was recognized by the physician who examined her. Negative results from a vaginal examination. Dr. Clark saw the patient later, and became convinced that there was suppurative inflammation of the psoas. Finally, pus was removed, and thirty-one aspirations were made before a cure was finally effected. The pus did not contain a trace of phosphate of lime.

The second case was in a young man, whose condition originated in strains during roller-skating. When he consulted his physician, Dr. Gould, he complained of pain in the region of the hip, and had a rapid, bounding pulse, the temperature 105°. Afterwards, copious perspiration of acid odor, etc., led to the diagnosis of rheumatism, but later, a boggy tumor appeared in the supra-pubic region. An exploratory puncture gave exit to foul gases, followed by pus. An opportunity to make an autopsy was afforded in this case, and a psoas abscess was found, which had led to denudation of the bone beneath, and there was also some softening of the vertebrae, but it was evident that the disease had originated in the muscle, and not in the vertebrae.

The third case was that of a man who first attributed his difficulty to rheumatism, from which he was a frequent sufferer; but it was learned that he had injured himself in the region of the psoas while throwing filled sacks upon a wagon. He complained much of pain in the neighborhood of the thigh. The pain was relieved by a local anæsthetic. A supra-pubic tumor developed, which, at a time when Dr. Clark had intended to open it, burst spontaneously into the bladder, and a quart of healthy pus was evacuated per urethram. Later, another opening for the escape of pus was made by the knife above Poupard's ligament, and then pus ceased to escape through the bladder, and finally, through the artificial opening, and the patient went on to complete recovery.

Dr. Clark pointed out in the differential diagnosis, history of traumatism, pain in the region of the thigh and leg, the posture of the patient, avoiding extending and rotating the leg, the supra-pubic tumor; and, on aspiration, obtaining laudable pus. In each instance, the syringing of the pus cavity was followed by washing out with solution of carbolic acid.

DR. FREDERICK HYDE believed that many cases of supposed vertebral disease were really cases of the kind related by Dr. Clark, and he urged with great earnestness the importance of making a careful search in suspected cases for a history of traumatism, for a pelvic tumor, and for pus by repeated use of the aspirator, if necessary; for the train of evils following a change of the laudable pus which was first present into unhealthy pus was too long and serious to permit of postponement of the case, with the idea that eventually the symptoms would demonstrate it to be a case of Pott's disease. It taken in the early stage, a cure could be effected and the bones would escape implication.

DR. CROMB, of Buffalo, had seen two or three cases of psoriasis, and said that in diagnosis, valuable aid would be found in putting the patient under the influence of chloroform, flexing the thigh, and searching for thuc-

tuation over the region of the psoas muscle. History of traumatism was important in diagnosing poitis. Let the pus escape; then keep the leg in the extended position, bringing the walls of the sac together, and union would rapidly take place.

Dr. MOORE thought that where it could be shown that the disease had begun with a traumatism, he thought it was unnecessary to try to explain its occurrence on the supposition of a tubercular inflammation. An acute disease might become chronic, and, of course, when this occurs there is a good opportunity for tuberculosis to develop. But the commencement may have been in fibrous tissue, thence to the bone.

#### NOTE ON TWO PECULIAR CONDITIONS OF THE MAMMARY GLAND.

By DR. S. T. CLARK.

The paper was read by title.

#### SHOCK AND THE EFFECTS OF INJURIES UPON THE NERVOUS SYSTEM.

Dr. CHARLES W. BROWN opened a discussion on this subject by a short paper, in which he described the symptoms present in shock, and referred briefly to the explanation which had been suggested of its nature. He had seen a few cases of what had been termed "insidious" shock, in which the patients did not suffer pain in proportion to the seriousness of the injury, and were of a cheerful state of mind, although there was almost a diagnostic melancholy expression upon the face, which seemed to foretell death. He also referred to individual susceptibility, and said that some persons of fleshy habit and apparent health would succumb to a minor injury producing shock, than some others of delicate habit and nervous temperament, the nervous system in the latter giving way less readily. Shock was less in persons suffering from chronic disease, but such persons were less likely to regain strength and make complete recovery afterward than those of previous good health, who might be able to withstand the first influence of the injury upon the nervous system. There were two indications in treatment: the first, to modify the effects of the shock; and the second, to control superinflammation. The use of heat and stimulants received some attention.

Dr. FRANK H. HAMILTON continued the discussion with a short paper, read for him by Dr. Birmingham. His remarks were limited to surgical shock, which, he said, might be defined as a general paresis of the nervous system induced by external violence. One point which received his attention was what is called railroad shock. Many of the symptoms which had been described as belonging to railroad shock were seen in certain cases of shock which occurred before railroads had come into existence. But, if he admitted that the introduction of railroads had brought into existence a particular kind of shock, Dr. Hamilton thought it was due to that sort of injury to the spinal columns which was likely to occur in railroad accidents, resembling the cracking of the lash of a whip. In these cases, he believed that the injury was not primarily in the nature of a shock resulting from commotion of either peripheral or central nerves, but that those structures which lie external to the spinal marrow and contribute more or less to its support and protection, of which the ligaments are the chief factors, are those which have suffered direct injury, and from which inflammation has subsequently progressed to the spinal marrow

itself. As to the treatment of shock, bring about reaction by rest, in some cases by warmth, stimulants.

Dr. EDMUND S. ARNOLD continued the discussion by a brief paper, in which he took the view that shock was due to an impression produced upon the sympathetic nervous system, tending to stop its function, and in doing so, stopping nutrition of vital parts over which that system of nerves presided. Sudden death would occur if such influence were sufficient to entirely destroy the function of this system of nerves or ganglia, as in lightning. Another illustration, he thought, was in death by hydrocyanic acid. If there was an influence upon the heart in this case, he thought it was directly due to suppressed function of the sympathetic system which presided over its action, and other parts of which system of nerves were also affected at the same time.

Some general discussion took place, Dr. Kneeland, Dr. French, Dr. Moore, Dr. Arnold, Dr. Van de Warker, and Dr. Hendricks participating.

#### INSANITY FOLLOWING AN INJURY OF THE HEAD— CEREBRAL CYST—OPERATION—RECOVERY.

Dr. CARLOS F. McDONALD read a paper with this title, the case being that of a man who received a pistol shot on the frontal region, inflicted by his own hand. The man was sent to prison, where he developed symptoms of insanity, and had to be confined to a cell. For a considerable period of time, however, he had been required, and was able, to do prison duty, but manifested a passionate temper. It was decided to trephine at the seat of the wound, which was half an inch in diameter, a fourth of an inch in depth, located over the right first frontal gyrus, corresponding to the junction of the anterior and middle third—three-eighths of an inch to the right of the median line. The patient was etherized, the wound was found traversed by dense fibrous tissue, no bone intervening between the dura mater. A fine hypodermic needle was introduced, and nothing was withdrawn until the fourth puncture, when about two drachms of serum were withdrawn. The fluid contained a few blood corpuscles, which were accidental. Nothing more was done than to close wound with suture and dress antiseptically. The patient, on coming from under the influence of the anæsthetic, was in his natural mind, was greatly pleased with relief from pain at the seat of the injury, and shortly afterward gave a satisfactory account of his case from the beginning, excepting a period when he was unconscious. He went on to complete recovery, with permanent relief from cerebral symptoms, except a part of the day. It was learned that the physician who saw him after the shooting, had removed the pistol ball; he found no fracture of the bone, or spicula.

#### FIRST DAY.—NIGHT SESSION.

The President in the chair.

#### DISCUSSION ON PNEUMONIA.

Dr. AUSTIN FLINT opened the discussion with a paper in which he propounded the following eight questions:

1. Is acute lobar pneumonia a primary local inflammatory disease, or is it an essential fever, the pulmonary affection being secondary thereto and constituting its anatomical characteristics?

Since 1877, when he read a paper in support of the

doctrine that acute lobar pneumonia was not a local affection, but an essential fever, that doctrine had been gaining ground. The view was supported by the following facts: *First.* Acute lobar pneumonia is characterized by an enormous exudation into the pulmonary alveoli, and this exudation may be rapidly absorbed, leaving the tissues intact. This anatomical fact, he said, had no analogy in local disease. *Second.* Acute lobar pneumonia never persists and becomes a chronic affection. *Third.* It is never referable to any appreciable local condition, nor is it possible by any form of traumatic injury to produce the affection. *Fourth.* Ordinary causes of local disease are not capable of producing acute lobar pneumonia. The traditional belief that the affection may be produced by cold is without foundation, and is being abandoned even by the Germans. *Fifth.* That a special or specific influence is invariably the cause of acute lobar pneumonia is rendered probable by its occurrence at certain seasons, greater frequency in certain climates, occurrence at times as an endemic disease. *Sixth.* It differs from acute primary local inflammation in that at the outset there is a pronounced chill. *Seventh.* In the course of the disease the temperature and associated febrile phenomena bear no constant relation to the local affection. *Eighth.* Experience shows that acute lobar pneumonia responds better to treatment addressed to the fever than to the local affection.

2. What facts and rational grounds, with our present knowledge, can be cited in support of the doctrine that acute lobar pneumonia depends on the presence of a specific microorganism?

DR. FLINT left this question for discussion to Dr. Janeway, but expressed his belief in a specific microorganism as the cause of the disease.

3. What conditions or circumstances incident to acute lobar pneumonia tend to render the disease fatal?

The present or previous existence of certain other diseases rendered the prognosis more unfavorable, and certain conditions, as empyema, pulmonary gangrene, malarial miasm, etc., were more likely to develop in one who had been reduced by pneumonia. But of special conditions rendering danger of a fatal issue in the course of the disease greatest, the author mentioned heart clot and heart failure.

4. Are there known remedies or therapeutic measures capable of arresting this disease, or of exerting a curative influence by either shortening its duration or conducing in any way to a favorable termination?

DR. FLINT had reason to believe that quinia had been of benefit in shortening or exerting a favorable influence upon acute lobar pneumonia, but he could not enter fully into discussion of the treatment.

5. Is blood-letting ever indicated in this disease, and if so, what are the circumstances indicating and contraindicating this measure of treatment?

Acute lobar pneumonia tended intrinsically toward recovery. Treatment in general should be for special indications. He believed there were circumstances in which blood-letting would prove of benefit, and that benefit would be most likely to manifest itself in relief of oppressed heart action. Contraindications to blood-letting were previous existence of enfolding affections and the anemic state. A plethoric condition and a bounding pulse were among indications for this measure. The collection of cases made some years ago by Lewes, in which there were twenty-eight deaths out of a total of seventy-eight cases in which blood-

letting was resorted to, showed a high mortality, but the cases were not selected.

6. Is alcohol useful in the treatment of acute lobar pneumonia, and if so, what are the indications for its use, and how is its use to be regulated as regards the quantity given, etc.?

The author regarded alcohol as indicated wherever there was required the supporting plan of treatment, wherever there was a tendency to asthenia. It should be begun tentatively.

7. To what extent is it safe and useful to employ antipyretic measures of treatment in cases of acute lobar pneumonia, inclusive of the cold bath, sponging of the body, or the wet sheet?

DR. FLINT spoke specially as to his experience with the wet sheet, which he had employed in three cases, with favorable results.

8. Do relapses of acute lobar pneumonia ever occur during or shortly after convalescence, and does this disease involve any special liability to other diseases or sequels?

The first part of the question the author answered in the negative, and said this fact was in favor of the view that the disease was an essential fever, for local diseases had relapses, but one attack did not exempt against subsequent attacks.

The first question propounded was discussed in brief papers by Drs. Didama and Ross; the second, by Dr. Janeway, who expressed regret at having been unable, on account of sickness, to make further investigations personally regarding the influence of a microorganism in the causation of pneumonia. He gave a synopsis of the literature of the subject. The third question was discussed by Drs. W. H. Robb and H. M. Biggs; the fourth by Drs. T. F. Rochester and Van de Warker; the fifth by Drs. S. T. Clark and C. S. Wood; the sixth by Drs. John Shrady and E. D. Ferguson; the seventh by Drs. G. Griswold, C. C. Stockton and W. S. Fuller; the eighth by Dr. J. G. Orton.

[To be continued.]

## Recent Literature.

*Diseases of the Rectum and Anus. Including a Portion of the Jacksonian Prize Essay on Cancer.* By HARRISON CRIPPS, F.R.C.S., Assistant Surgeon to St. Bartholomew's Hospital, London. 8vo. 430 pages. Philadelphia: P. Blakiston, Son & Co.

The stimulus offered for original work by the establishment of Prize Funds does not necessarily cease with the gaining of the prize, but the distinction and satisfaction resulting from the thorough study and mastery of some one subject stimulates further effort which often results in great benefit to the profession, as in the work before us. In 1875 Mr. Cripps wrote the Jacksonian Prize Essay on Cancer of the Rectum, which was a valuable contribution to our knowledge of the pathology and treatment of this disease.

The present volume, an outgrowth from the collateral research involved in the study of rectal cancer, is devoted to the consideration of the other disorders incidental to the same locality that have come under his observation at St. Bartholomew's Hospital. It contains some 430 pages and is written in a very attractive manner, showing evidence of being the result of

personal experience based upon anatomical and clinical investigations. The illustrations are numerous and good. In the chapter devoted to "the anatomy of the rectum and the functions of its mucous membrane," we would call attention to the description of the *levator ani*, their sphincter-like action, and (later on) its possible bearing on the pathology of rectal stricture. In his description of the mucous membrane of the rectum, we are surprised that the author makes no mention of any folds known as Houston's valves, and conclude that he has never seen them.

The chapter on *Hæmorrhoids* is very satisfactory, especially his observations on external *hæmorrhoids*; in dealing with internal *hæmorrhoids* he states his preference for the ligature which "if properly used leaves little room for improvement," a conclusion not borne out here where the operation by clamp and cautery has proved more satisfactory. Mr. Cripps' remarks on Stricture of the Rectum are exceedingly interesting and instructive, and cannot fail to impress the reader as being both practical and instructive.

The chapter on Cancer of the Rectum is a portion of the prize essay to which reference has already been made. He has found that all forms of so-called rectal cancer conform to one type, the adenoid, and assume two main forms, namely, one where it forms a thin flat layer between the mucous and muscular coats, and when ulcerating makes an ulcer with a base formed by the hypertrophied muscular coat with crater-like margins; the other where it forms from the first a projecting tumor, clinically innocent; that these growths are developed from lymphoid cells originally derived from epithelium, that these lymphoid cells not finding their way into the lymph channels become fixed, develop into epithelium, and give rise to a formation reproducing the characters of gland tissue.

Mr. Cripps advocates colotomy for this disease in those cases where local interference is impracticable, not with any idea that the progress of the tumor would be retarded thereby, but as a means of alleviating symptoms which if not relieved would of themselves prove fatal. Excision of the rectum either complete or partial he regards as justifiable if there is a reasonable prospect of its being possible to remove the whole disease, but unfortunately, the cases which admit of extirpation he states as comparatively rare, probably not more than ten to twenty per cent. of the cases of the disease applying to the surgeon.

— Prof. Asa Gray, the celebrated botanist of Harvard University whose seventy-fifth birthday was celebrated by his friends, November 18, was born in Paris, New York. He was educated as a physician at the Fairfield Medical College, where he was graduated at the age of twenty-one. He was appointed Fisher Professor of Natural History at Harvard University in 1812.

Painstaking the pharynx with a two-per cent. solution of cocaine, according to Dr. Ladose (*Bulletin Gènevois de Thérapeutique*, August 15, 1885), entirely prevents the production of dyspnea during the introduction of the stomach-tube; and, since this procedure is very day becoming more frequently employed as a therapeutic measure, it is well to know that the discomforts attending its use may largely be done away with by the employment of cocaine.

## Medical and Surgical Journal.

THURSDAY, NOVEMBER 26, 1885.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly, by CUPPLES, UPHAM & CO., Boston. Price, 15 cents a number; \$5.00 a year, including postage, to subscribers in the United States and Canada. Foreign subscribers are charged the postage in addition.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.*

CUPPLES, UPHAM & COMPANY,

253 WASHINGTON STREET, BOSTON, MASS.

### THE DANGERS FROM COAL GAS.

The return of the season when furnaces and coal stoves begin their period of activity, suggests a danger which, although alluded to in the medical press from time to time through the report of serious or fatal cases resulting therefrom, does not perhaps receive the attention its importance would justify.

A person complains of general symptoms of malaise with debility, often a dry irritative cough, anorexia, anæmia, drowsiness, mental inertia, and usually more or less intense headache. On examination no special organ seems to be at fault. The physician is at a loss, and, after ordering an inspection of the plumbing with negative results, and looking hard at the wallpaper, he either suffers himself to lapse into that limbo of medical diagnosis "malaria," wherein, in a literal use of the word he is nearer the truth than he has a right to believe himself, or else contents himself and his patient with the obvious statement that the latter is "run down." Quinine is prescribed with some advantage, and if more out-of-door exercise and especially a little journey are prescribed the patient gets well, and passes into the large category of cases described by an eminent English physician, who said that half his patients got well without his knowing what was the matter with them.

Or again, perhaps in the same house occurs an acuter case. A man who has slept in a chamber with closed windows is found in the morning stupid, confused, with indications of having vomited, thick in speech and staggering in gait, and with a raging headache. The physician's first inquiry is, if the patient dined out the previous evening, and he is disappointed to receive a negative answer. The time of year excludes the possibility of insolation, and if, as is possibly the case, the history as given by friends shows something not unlike this attack to have occurred before, the view of the physician inclines towards nocturnal epilepsy, and as usually happens, the speedy recovery takes away the motive for a closer study of the diagnosis.

Thus not until a case comes under observation, and perhaps not until two occur in the same room, or sev-

eral in the same house, presenting extreme symptoms, is the true cause of the trouble recognized. The patients are unconscious, with stertorous and rapid respirations, sometimes manifesting the Cheyne-Stokes phenomenon. There is perhaps frothing at the mouth, and mucous râles are heard in the lungs. The conjunctivæ are insensitve and the pupils dilated and unresponsive. The pulse is rapid and feeble. Convulsions may appear with tonic, passing into clonic spasms. There is vomiting with purging, and as consciousness returns, intense headache. As has been said, a plurality of cases in one room or house may give the first clue to the cause of the trouble.

The literature of this subject, already not very scanty, has received a valuable addition in a report of two cases, made last June, before the college of Physicians of Philadelphia, by Dr. John Graham. An aged couple went to bed together in good health, at 10 p.m. They afterward could recall nothing amiss except that the smell from the heater was a little stronger than usual. Fourteen hours later they were found, both unconscious. The symptoms were at that time in the main similar to those that have been reported by other observers. In the husband, aged seventy-eight, the labored breathing remained, the blood became more carbonized, and he died without regaining consciousness, in thirty-six hours. The wife, aged seventy-four, responded better to treatment and gained slowly. In seven days she was able to sit up a little. She still remained drowsy, often half conscious, and complained of noises hurting her head. Anæmia was very marked, though the blood was not examined. Carbonate of iron was given, which impaired the digestion, and at the end of the third week she had an attack marked by loss of consciousness with convulsions. The lateness of the convulsions is one of the notable features of this case. They were followed by mental confusion and hallucinations, with marked aphasia. Every attempt to give iron induced such digestive disturbance that it had to be abandoned, while under the use of dilute muriatic acid, the tongue would clear. On the forty-second day there was an attack of alternate paralysis, preceded by muscular twitchings, and affecting the right side of the face and the left arm. From this she recovered in ten or twelve days. Dr. Da Costa, who saw the case, considered that the paralytic symptoms were due to anæmia of the brain. It was not until the fifty-eighth or sixtieth day that iron was productive of any good effects. The form then selected was the phosphate of iron with citrate of ammonia, which Dr. Da Costa has found one of the most easily tolerated and digested combinations of this remedy.

Of the gaseous products of the combustion of coal the principal are two, carbonic oxide (CO) and carbonic dioxide (CO<sub>2</sub>) commonly called carbonic acid gas. The former is actively poisonous, the latter simply irrespirable. The carbonic oxide which is, of course, the product of a less complete combustion, forms a compound with hæmoglobin which is very difficult to

break up. The compound of the dioxide with hæmoglobin, on the other hand, is readily split up by increasing the tension of the free oxygen in the blood. It is probable that the peculiar anæmia, so obstinate to treatment by iron, is due to the modified condition of the hæmoglobin, and the tenacity with which it holds on to the carbonic oxide.

The sources of this poison are not difficult to find. In the furnaces, which heat the majority of our houses, there is a hot-air chamber from which the distributing pipes are supplied. The smoke-flue is often led through this chamber, and sometimes to economize heat it is carried for quite a distance downward to the bottom and thence up again through the hot-air chamber. The joints are often not tight, and even if they were originally so, become loose with the wear of the heater. In the case cited above, in Philadelphia, the smoke-pipe was of terra-cotta, and ran through the hot chamber. This pipe had a crack half an inch wide and eighteen inches long, allowing, of course, the gases to mingle with the air of the supply chamber. Even where no actual crack exists, it has been shown that carbonic oxide may pass through heated cast-iron plates. If, therefore, the furnace is run so that the iron work becomes red-hot, there may be a diffusion of this most poisonous gas into the hot chamber, and thence all over the house. If, now, there occur an obstruction to the appointed smoke escape, by an obstruction in the chimney, or even by a widely-opened draft in the flue, or a down draft, the products of combustion find their most natural vent into the sleeping-rooms of the house, instead of into the outer air. Both the gases are tasteless and odorless, and unless mingled with the irritative constituents of smoke, which will not be the case after a firm bed of coals has been established, attract no notice through any of the senses. In Dr. Graham's cases, the chimney, which had several angles, had become obstructed by bricks and mortar, which, loosened by the frost, fell and lodged at one of the bends, causing considerable obstruction to the draft.

The chances of recovery in acute carbonic oxide poisoning depend, as is well known, on the amount of the gas inhaled, and this depends on the length of the exposure, as well as on the size of the room and the amount of pure air introduced from outside. It is probable that most of the serious cases are due rather to the CO than to the CO<sub>2</sub>, the former gas being lighter than the air, while the latter is heavier. This accounts for the similarity in the symptoms to those of poisoning by illuminating gas.

The treatment in acute cases is, of course, primarily fresh air and stimulants, hypodermically and by rectum. Transfusion, and the modification of it known as refusion, namely, a withdrawal of the vitiated blood and a transfusion of fresh blood, may be of great service. The prophylaxis depends upon ventilation of the living-rooms, upon a free and unobstructed chimney draft, upon tight joints and an avoidance of overheated furnaces. Perhaps the hygiene of the domicile

depends as much upon the designer and maker of our heaters as upon the plumber.

### STRANGULATED UMBILICAL HERNIA.

THE attention of the profession has of late been called anew to the operative treatment for strangulated umbilical hernia by the report of two cases by Mr. Clement Lucas at a meeting of the Clinical Society of London, held October 9th. In this report Mr. Lucas endeavors to account for the high rate of mortality hitherto following instrumental interference, and to lay before the notice of the profession the most rational means for reducing it. He strongly advocates the removal of the sac, and the suturing of the patulous umbilical ring; and this not on the ground of safety alone but for the incidental advantage to the patient of obtaining a radical cure. He regards "the sac itself as a danger from its badly nourished texture, its tendency to suppurate or slough, and its liability to collect discharges and guide them into the peritoneal cavity," and strongly advises that that useless and dangerous piece of tissue be removed. His two cases certainly furnish strong evidence in favor of the method. The first case was a woman of forty-eight, who was also suffering from renal dropsy in an advanced stage. The taxis having failed, the sac was laid open freely, when fluid escaped and a long coil of purple intestine came into view. It was found impossible to reduce the hernia, even after the constriction was divided, until a large quantity of ascitic fluid had been drained off through the wound. The sac was then cut away, and the margins of the umbilical opening brought together with three stout catgut sutures passed through to, and including, the peritoneum. For the skin wire sutures were used. The recovery was uninterrupted, except that a slight suppuration was caused by one of the catgut sutures, which came away on the fifteenth day. Two months later there existed no tendency to umbilical protrusion.

The second case was a woman of fifty-two years, extremely fat and flabby. Taxis having failed, a four inch vertical incision was made over the upper part of the tumor, the sac was laid open, the stricture divided, and several feet of dark colored intestine returned. There was in this case an ommental sac lining, the one of peritoneum and in parts adherent to it. As much as possible of sac and omentum were removed, and the edges of the umbilical opening brought together with catgut as in the first case. In three weeks the patient had recovered from the operation. In both cases carbolic spray and antiseptic dressings were used.

In the subsequent discussion the weight of opinion was in favor of the operation, especially in cases presenting unusual difficulties. The procedure had been adopted several times with success by other surgeons present at the meeting.

The interest shown in the subject induced Mr. Rivington, of the London Hospital, to report in the *Lancet* of October 24th, several cases of hernia, which

had been treated essentially in the same manner as that advocated by Mr. Lucas, and among them two cases of strangulated umbilical hernia. The results in both were perfectly satisfactory. Mr. Rivington affirms that the removal of the sac or omentum after the bowel has been reduced cannot, in most cases, add appreciably to the risk of an operation.

In the issue of this JOURNAL, for October 16, 1884, Dr. A. T. Cabot urged the importance of removing the sac and suturing together the peritoneal surfaces around the ring under strict antiseptis, so as to shut off the abdominal cavity from any suppurative action which may take place in the wound. He there says that "the wound left by an operation done in this manner for umbilical hernia differs in no essential particular from the simple incised wound of an ovariectomy," which almost invariably heals readily, the peritoneal surfaces, when snugly approximated, cohering within twelve hours. The case which he records recovered from the operation, but died about three weeks afterwards from causes not directly traceable to the operation, but to her own indiscretion.

In the same issue of the JOURNAL Dr. H. L. Burrell reported a case, in which he performed this operation on a woman of fifty-two years, weighing 230 pounds. Owing to the great thickness of the abdominal wall it was necessary to make a vertical incision reaching from the top of the tumor to a point four-fifth inches up the linea alba — practically an abdominal section. The sac was excised and the wound brought together by deep wire sutures which included the peritoneum. A perfect cure resulted.

Judging from the results of all cases published, and from the opinion of competent surgeons, as well as from the reasonableness of the operation itself, it would appear that this comparatively new method is to be recognized as a distinct advance in surgical science, and as applicable to all cases of strangulated umbilical hernia, which present unusual difficulties in the way of reduction. The principles to be borne in mind are removal of the sac, ligature of the ring by stitches passing through the peritoneum, and strict antiseptis.

### PUBLIC SCHOOL "TEMPERANCE TEXT-BOOKS," AND TEACHING ON PHYSIOLOGY AND HYGIENE.

UNQUESTIONABLY one of the most serious, and most deeply-rooted evils affecting our population is that of alcohol in its effects upon the physical welfare of man. The number of criminals who fill our public prisons, jails, and reformatories, of inmates who have been committed to asylums for the inebriate and insane, of those who have sought admission to hospitals in consequence of the effects of alcohol; of the children of these persons who are destined to fill similar institutions in consequence of their inherited traits; the support of the courts and tribunals which have jurisdiction in such matters; the enormous burden of taxation

imposed upon the people for the support of all these, make this one of the most important questions, moral, physical, and economic, of the present day.

Legislative action has been sought and laws enacted under the name of prohibitory, and license, which fail to remedy the evil, either on account of the want of proper executive authority, or of adequate support on the part of the people.

Failing of these means, attempts have been made in Massachusetts and in other States to secure such legislation as should lead to reform in a different direction — by the education of the young — the honest intention of the framers of the law evidently being to teach the scholar in the public schools the action of alcohol upon the human system, on the principle "As the twig is bent, the tree is inclined."

We shall not attempt here to discuss the propriety of such a statute. Under proper instruction and with discretion in methods of teaching, doubtless good may be accomplished. Harm may also be done by wrong methods and the lack of discretion, and we have before us examples of the very exaggerations and indiscretions which we feared and anticipated when some of these legislative bills were under discussion.

The recent agitation of this subject has led to the publication of an unusual number of text-books, some of which are well adapted to the purposes for which they are designed, the subject being treated in an intelligent and careful manner, and with freedom from sensational and exaggerated statements.

On the other hand, other text-books now in use in the schools contain much that is questionable, both in matters of fact as well as the method of presentation.

As an introduction to the study of myology, the following is not calculated to inspire the pupil with enthusiasm: "The skeleton is the image of death! Its unsightly appearance instinctively repels us; We have seen . . . how the ugly-looking bones abound in nice contrivances." <sup>1</sup>

The following statement from the same text-book can hardly pass unquestioned: "Dr. A. B. Hall says that he once bled a man who was dead drunk. The blood was caught in a bowl, and on applying a lighted match, the liquid blazed up at once. Experiment shows that to do this it must have contained twenty per cent. of alcohol." The author of this statement has long been dead. The experiment, however, lacks confirmation. Let the assertions in this quotation be considered in connection with each other. *First*. Blood flowing from the body of a drunkard ignited on the application of a lighted match. *Second*. Blood must contain twenty per cent. of alcohol, in order to blaze or ignite. The amount of blood in the body is variously estimated, the estimate given in the same book being one-thirteenth of the weight of the body, or ten pounds in an adult of 130 pounds. Twenty per cent. of this, or two pounds of alcohol would represent four pints of brandy or ten to fifteen pints of wine existing in the circulation, to say nothing of such

quantity as might also remain in the cavities, or organs of the body, stomach, bladder, etc.

While there is no definite information on this subject, the query arises, how long would human blood continue to circulate without coagulation, while containing twenty per cent. of alcohol, or even ten or five per cent. of a substance so decidedly poisonous? The same book appears to give evidence contrary to the preceding statement, for example: p. 130, "A quart drunk at once would kill like a bullet;" p. 133, "Even so small a quantity as one part of alcohol to 500 will materially check the absorption of oxygen in the lungs."

In another place appears the following assertion: "An infant kept in absolute darkness would grow up a shapeless idiot." A bright scholar in one of our public schools, on seeing this statement, inquired of her teacher if all children born blind were shapeless idiots. The sensational colored plates introduced in the same book to illustrate the effects of alcohol on the stomach, might with propriety find a place in a patent-medicine almanac, but such travesties upon pathology should never form a part of a system of education. Especially should the wretched plum-pudding-like figure at the bottom of the page, entitled *cancerous stomach*, have been omitted, not only on account of its utter want of accuracy, but also as having no connection either possible or probable, with the subject of alcohol.

Singularly enough, this text-book is accompanied with a circular endorsed by twelve persons, not one of whom is an expert in physiology or hygiene; not one, in fact, is a physician; eight of the number are clergymen, and one has the remarkable adix R.W.G.V.T., S.O.G.T., whatever that may be. It intended to give weight to the endorsement, the remainder of the alphabet is at command.

It is time that the endorsement of text-books intended for the purpose of teaching special branches, should be intrusted to "practical experts in the matters concerned," as is claimed for this book in the circular referred to.

#### THE SALE OF POISONS.

Two recent occurrences in Boston illustrate forcibly the laxity of the law and of actual practice regarding the sale of deadly poisons and of dangerously poisonous articles.

In the one case a young lawyer, apparently prospering in his profession and happy in all his surroundings, was found dead in his office, with evidences of death having been caused by cyanide of potassium.

In the other case all but three members of a large family, occupying a house in the most fashionable part of the city, were suddenly taken with nausea, vomiting, diarrhea, great thirst accompanied by headache, soreness of the limbs, edema of eyelids — symptoms continuing in some measure for a week or ten days. The attending physician recognized the symptoms of an irritant poison — probably of arsenic — when con-

<sup>1</sup> Hygienic Physiology for High Schools, By J. D. Steele, Ph.D.

sulted, but it was some time before the cause of the trouble could be discovered, and in the meantime every member of the family suffered severely.

The bread was finally hit upon as the cause of the trouble, and with the aid of chemical analysis, the flour was proved to contain arsenic. After removing the top layer of flour for two or three inches a large deposit of gray substance was found which proved to be a mixture of white arsenic and charcoal, either the preparation known as "Rough on Rats" or some similar one. The family had a narrow escape. In one or two more bakings this mass would have been reached, and, had it passed unnoticed, would undoubtedly have proved fatal to all eating the bread, although, we understand, the determination of the exact quantity of arsenic has not as yet been determined.

Four or five days before the outbreak of the first symptoms a cook, who had been but a short time in the family, was discharged. The reasons for suspecting her of connection with the poisoning were sufficient to cause her arrest and detention for trial.

In the meantime the police are anxious to know where the poison was purchased. An inquiry of this sort is attended with abundant uncertainty, for "Rough on Rats" and other vermin killers containing deadly poisons can be bought by almost any one and no questions will be asked. Moreover, we believe that many of these preparations are extremely uneven, a large portion of the poison being concentrated in one part of the mixture, perhaps, and but little in another.

The Massachusetts Statute on the sale of poisons reads as follows: "Whoever sells arsenic, strychnine, corrosive sublimate, or prussic acid, without the written prescription of a physician, shall keep a record of the date of such sale, the name of the article, the amount thereof sold, and the name of the person or persons to whom delivered; and for each neglect shall forfeit a sum not exceeding fifty dollars. Whoever purchases deadly poisons as aforesaid, and gives a false or fictitious name to the vender, shall be punished by a fine not exceeding fifty dollars."

Something more than this and more stringently enforced is evidently necessary for protection against such events as the two above detailed.

#### MEDICAL NOTES.

—A class of fifteen was graduated from the Medical Department of Dartmouth College, November 17.

—In Spain the progress of the cholera from September 29 to October 8 inclusive, was 3,531, with 1,411 death. This makes the total reported cases in that country 271,223, with 100,370 deaths. Since Oct. 13th no new cases have been reported from Gibraltar, although up to the end of the month there was sporadic cases in the neighboring villages. Since Nov. 1st clean bills of health have been issued from Cadix.

The death-rate from small-pox has of late been daily diminishing in Montreal.

The *Lancet* remarks that a peculiar sensation of

numbness, or "pins and needles" in the extremities is frequently experienced by dentists. This condition, Dr. George Johnson considers to be due to the combined influence of perverted nerve-function, directly due to a mechanical impediment to the circulation through the rigidly contracted muscles and their associated nerves, and to direct compression of the nerves by the firmly contracted muscles. This combination is found in dentists who stand fixed and firm in one position for long periods of time. The obvious means of prevention and of cure consist in rest for the overstrained limb, or such a frequent change of position as is equivalent to a certain amount of rest. Standing in one position is notoriously more fatiguing than walking, and for the obvious reason that while in standing one set of muscles is in a constant state of active contraction, the circulation through them being thereby retarded and enfeebled, walking involves alternate contraction and relaxation of the muscles, with an invigorated and quickened circulation.

#### BOSTON.

—A case has recently occurred of the poisoning of several members of a family in Boston by means of arsenic which was mingled with the flour used for domestic cooking. A cook was discharged October 26, and her place was at once filled. The next day the family had some newly baked bread, and during the evening one after another was taken sick. The symptoms were vomiting, with great pain. Two boys and a servant only escaped, and they, as was afterwards remembered, ate none of the bread. The sickness of the other members of the family continued for two or three weeks with no improvement. The servants were most seriously affected. Finally the boys one night partook of some toast and were soon after taken sick. A dog fed with the bread was also made sick. A beggar who had been given some bread has been since found to have suffered in a similar way. An analysis of the flour showed arsenic in large quantities. A scoop from the middle of the barrel contained a great amount of the poison. Suspicion fell upon the discharged cook, and after some difficulty she was traced and arrested; but attempts to fix the purchase of the poison upon her have as yet failed.

—The "Hæmorrhage Trick," so called, has been practiced upon a number of good people, in various suburbs of Boston within a few weeks past. A poor man is found lying on the ground with much bright blood upon his lips and his attire. A good Samaritan comes that way to whom the afflicted man explains that he has accomplished most of the distance from Jerusalem to Jericho on foot in search of work and could easily have finished the journey had he not had this bleeding from the lungs. The good Samaritan, moved with pity for the man's sad condition, does not exactly set him upon his own beast and take him to an inn, but after the changed conditions of the nineteenth century, renders an equivalent service. He gives the sufferer a bank note and advises him to take the first train for a hospital. Such a one recently met a fellow Samari-

tan who had had a similar experience the previous day upon the same road, and the two compared notes. Investigation has showed that there is in Jerusalem a store-house from which "hamorrhage material" is supplied to whoever of the brotherhood of wayfarers requires it. Meantime the priest and the Levite are disposed to rejoice over the Samaritan and are confirmed in their policy of passing by on the other side.

#### PHILADELPHIA.

##### *Notes of Autopsy of John McCullough.*

Owing to the prominence given by the daily press to the case of Mr. John McCullough, the public has been kept fully acquainted with the history and progress of his malady, up to the time of his death in this city on the 9th inst. Desiring to avoid further publicity the family decided at first not to have an autopsy, and the body was placed in a receiving vault at the Monument Cemetery. Subsequently, they requested that the brain alone should be examined. On the 18th inst., therefore, nine days after death, the post-mortem examination was made by Dr. Hugo Engel, who had been the attending physician, Dr. Chas. K. Mills, Dr. Frank Woodbury, Dr. J. Hendrie Lloyd, Dr. J. M. Barton, and other medical gentlemen, who had been invited by the relatives to be present. The body showed no signs of decomposition; the globes of the eyes were shrunken, and the nose thin. The air of the vault was dry and pure.

The head only was examined. The aponeurosis of the occipito-frontalis muscle instead of being loosely connected with the pericranium was rather adherent. Nothing abnormal was detected (neither scar, depression, or marked irregularity of contour) upon the outer or inner surface of the calvaria, to which the dura mater strongly adhered. Upon the upper surface of the dura mater, along the lateral borders of the superior longitudinal sinus, and most marked at the vertex, were observed granular bodies or small pearly masses without corresponding depressions in the bone. No marked abnormality was observed in the dura: no discoloration, thickening, or evident inflammatory change.

It was noted, however, that some of the vessels of the dura mater, notably in the left temporal region, had rigid, almost cartilaginous walls, without being obviously enlarged. Upon removing the brain the absence of the usual amount of cerebro-spinal fluid was noted. (It had probably been imbibed by the tissues in the long interval which had elapsed since death.) The large venous branches in the pia mater were prominent, and contained dark blood, their walls were thickened, and in some places cord-like. The pia mater showed milky opacities, most marked over the fissures, notably the Sylvian and Rolandic, and along the course of the vessel. The same condition of the pia as to opacity and vascularity, was observed to extend to the cerebellum. The brain structure was remarkably well preserved, but the large ganglia and corpus callosum were quite soft and were torn in manipulating the brain during its removal from the skull. At the point of greatest

opacity of the pia, over the convexity of the left hemisphere, the cortical layer of brain tissue came away in several places when the pia was torn away; this was not noticed in others. Deep in the fissure of Sylvius, adhesions were found between the adjoining lobes.

The basilar artery, both middle cerebral arteries and their branches, showed marked degenerative changes in their walls. White deposits were seen and felt, and some of the smaller arteries had their lumen almost, if not totally, occluded by such deposits. (These vessels named were secured for microscopic examination.) Sections of the hemispheres and of the large ganglia, did not reveal any gross lesions beyond those already quoted.

A more careful and detailed report of the autopsy, it is understood, will be prepared. The euphemism of "blood poisoning," so frequently repeated in the daily papers, is well understood by the profession, fully accords with the revelations of the autopsy, but is not in any way inconsistent with the previous diagnosis of general paresis.

#### NEW YORK.

— The new Mount Olivet Crematory, on Long Island, was privately tested November 10th. The bones of an ox were used for the purpose, and the working of the apparatus employed is said to have been entirely satisfactory.

— Dr. Cyrus Edson, of the Health Department, has commenced a very important work in the investigation of the ice-supply of the city, and he recently reported to the Board that the ice obtained from a pond near the King's Bridge road is impure, the water being polluted with sewage.

— The Twenty-second Annual Meeting of the New York Society for the Relief of the Ruptured and Crippled, was held at the Society's hospital, corner of Lexington Avenue and 12d Street, November 10th. During the year then closed, 8,317 new cases were treated, of which 187 were received into the wards as in-patients. The number of visits from continued dispensary patients amounted to 45,573.

— A number of cases of small-pox have been discovered in the city during the past week, and one of the patients was a street-car conductor, who was found collecting fare in a crowded car with the eruption actually out on his face. Five cases were discovered in a large, double tenement house in Yorkville, where efforts were made by the inmates to conceal some of the patients from the sanitary authorities.

— The graduating exercises of the Brooklyn Training School for Nurses were held at Historical Hall, Brooklyn, November 29th, when diplomas were presented to a class of ten graduates by Mayor Low. Addresses were made by the Mayor, Dr. J. C. Hutchinson, Gen. Stewart L. Woodford, and the Rev. Dr. T. B. McLeod. Six nurses were graduated November 12th from the New York State Training School, in connection with the Brooklyn Maternity, the annual meeting of which was held at the same time.

— Some time ago, several families living in an up-town apartment-house near Fifth Avenue, discovered that certain of their members had been poisoned by sewer-gas, and vacated their apartments. Thereupon, the landlord sued them for rent for the remainder of their terms, which they refused to pay. When their case came up, they established to the satisfaction of the court, the fact that sewer-gas was present in the house, and the suit has been decided in their favor by the judge before whom it came, on the ground that the landlord was responsible for the sanitary condition of his premises.

### Miscellany.

#### HYDROBROMATE OF HYOSCINE.

A PREVIOUS issue of the JOURNAL contains an extended reference to Prof. H. C. Wood's observations on this drug. In the September number of the *Therapeutic Gazette* the same author publishes an additional note upon his experience with it. The dose for an adult he places at one-eighth of a grain. In spermatorrhoea he believes it to have a specific field of usefulness; thus, in a case in which the discharges were three a week, they were completely arrested by a dose of one-seventy-fifth of a grain at bedtime each night. The effects of the drug do not seem to be very lasting, but they are quite evident during its administration. It was employed in the penitentiary by Dr. Robinson, who reported that its results were surprisingly good. In a case of a woman with eroto-mania, its influence was also decidedly beneficial. As a hypnotic it is useful where sleep is prevented by too great cerebral activity, by a succession of thoughts, or where sleep is disturbed by urgent dreams. In intense fever with delirium, the hyoscine has seemed to control this symptom. Used hypodermically, in one case it seemed to produce a paralyzing effect upon the pneumogastric nerves; the patient, a woman, had an attack of suffocation, apparently paralytic and laryngeal. The dyspnoea of a child suffering with anginous scarlet fever was much increased after taking the drug, and in the course of an hour or two death resulted, whether from the use of the drug or not is uncertain; but these two cases are sufficient to arouse suspicion.

#### SCARLATINIFORM RASH PRODUCED BY INTESTINAL ABSORPTION OF PTOMAINES.

A PATIENT observed by MM. Lépine and Mollière (*Journal de Med. et de Chir. Pract.*, 1884) presented at first nothing abnormal, except an artificial anus, the consequence of a strangulated hernia. One day he was suddenly seized with violent delirium, and M. Mollière noticed a considerable dilatation of the pupils. The skin was covered with a scarlatiniform rash, but there was neither fever nor angina. Poisoning by belladonna was at first suspected; but, after a careful examination, M. Lépine came to the conclusion that the symptoms were due to the absorption by the intestine of ptomaine, acting like atropine, and probably similar to that obtained by Zuelzer and Sommerschein from putrid substances. After a short time, acute conjunctivitis and fever supervened, and the patient died. At the post-

mortem examination, a highly offensive substance was found in the intestine below the artificial anus, so that the possibility of an acute auto-intoxication cannot be disputed.—*British Medical Journal*.

#### DEATH OF DR. A. T. KEYT.

DR. A. T. KEYT, who died suddenly, November 7th, at his house in Cincinnati, at the age of fifty-eight years, was well known in connection with the application of the spymnograph to medical diagnosis. He contributed a number of articles to this and other medical journals, upon this and kindred subjects.

#### THE ELIZABETH THOMPSON SCIENCE FUND. A NEW ENDOWMENT FOR RESEARCH.

A LADY, residing in Stamford, Conn., who has been well known in that locality, for her benefactions to causes of religion and philanthropy, but who has never had any special interest in any particular branch of science, has given a fund consisting of \$25,000, of which the income, in the words of the letter of conveyance, "is to be devoted to the advancement and prosecution of scientific research in its broadest sense; it being understood that to provide for, and assist in, the maintenance of an international scientific association, is a method of application which seems to me very desirable."

The trustees are left with very great discretionary powers, which are to be guided by certain general directions. It is, above all, expressly understood that the prime object is to contribute from the income towards defraying the cost of scientific researches. The board of trustees consists of five members: Dr. Henry P. Bowditch, chairman; William Minot, jun., treasurer; Prof. Edward C. Pickering; Gen. Francis A. Walker; and Dr. Charles S. Minot, secretary. It was considered important to have as great a variety of interests represented as possible, and this is accomplished by the association of the above gentlemen.

When the International association is organized (and it is hoped that the movement will be initiated by the British association at Aberdeen), the income of the fund will presumably be expended under the direction of that new association; until then under the direction of the trustees. A moderate sum is now available, and persons who are carrying on original scientific research, and are in need of assistance therein, may communicate with the secretary.

#### RESISTING ELECTRIC SHOCKS.

DR. A. L. HUMMEL recounts some curious cases of recovery from shocks, which ought, according to all ideas upon the subject, to have proved fatal. Two of them are given in the *Popular Science News*. One is that of an *employé* of the Brush Company, who, while still grasping the wire in his left hand, cut it with a pair of nippers held in the right. The current was at once established through his body; and he was held to the wire at the top of a thirty-foot pole for three minutes at least, by which time a ladder had been procured, and he was released by a fellow-workman. During this time a current of three thousand volts, or sufficient

to run fifty arc-lamps of two-thousand-candle power, had apparently passed through his body; yet he was able to reach the pavement with slight assistance, suffered little or no constitutional disturbance, save a slight rise in temperature, and was not confined to his bed. His punishment was limited to the charring of three fingers on the left hand, and a small but deeply burned hole in the palm of the right hand. The only treatment was that applied for simple burns. Another case was afforded by one of the workmen of the Bell Telephone Company, who, having climbed a pole belonging to the Brush Company in order to carry a

wire over it, grasped the tie-wire of the positive line with one hand, and that of the negative line with the other. Here he was held until an assistant ran five squares to the electric-light station, when the circuit was broken, and he was released. A rope had been attached to him, and passed over the arm of the pole. This was held by another man, and he was thus prevented from falling. Though unconscious for a while, he soon rallied; but his pulse never exceeded 86, nor his temperature 101°. The thumb of the left hand was burned nearly off, as were also the index and middle fingers of the right hand. These were all amputated.

## REPORTED MORTALITY FOR THE WEEK ENDING NOVEMBER 14, 1885.

Population by State Census, of May 1st, 1885.

Deaths reported 2,082; under five years of age 600; principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, fevers, and diarrhoeal diseases) 372, consumption 310, lung diseases 190, diphtheria and croup 176, typhoid fever 37, diarrhoeal diseases 11, malarial fever 31, scarlet fever 27, whooping-cough 19, cerebro-spinal meningitis six, measles five, erysipelas three, such-pox two, puerperal fever two. From malarial fever, New Orleans 15, Brooklyn seven, New York five, Philadelphia three. From scarlet fever, Philadelphia eight, Brooklyn six, Chicago five, Boston, four, Cambridge and Salem one each. From whooping-cough, New York 14, Brooklyn and New Orleans two each, Baltimore one. From cerebro-spinal meningitis, New York three, Nashville, Holyoke and Brockton one each. From measles, New York four, Chicago one. From erysipelas, New York, Philadelphia and Boston one each. From small-pox, New York and Chicago one each. Puerperal fever, Chicago two.

One case of small-pox was reported in Chicago.

Cases reported in Boston: scarlet fever 34, diphtheria 21, and typhoid fever 22.

In 109 cities and towns of Massachusetts, with a population

of 1,327,813 (population of the State 1,911,655), the total death-rate for the week was 11.57 against 16.26 and 15.08 for the previous two weeks.

For the week ending October 31st, in the Swiss towns, there were 27 deaths from consumption, lung diseases 11, diarrhoeal diseases seven, typhoid fever five, diphtheria and croup four, whooping-cough four, small-pox three.

The death-rates were: at Geneva 10.1; Zurich 9.7; Basle 18.9; Berne 26.4.

In the 28 greater towns of England and Wales, with an estimated population of 8,906,116, for the week ending October 31st, the death-rate was 18.9. Deaths reported 3,075. Infants under one year of age 778 (deaths in London 1,340), acute diseases of the respiratory organs (London), measles 65, whooping-cough 64, diphtheria 54, scarlet fever 33, fever 32, diphtheria 19, small-pox (London four, Nottingham and Preston one each) six.

The death-rates ranged from 9.7 in Norwich to 21.0 in Plymouth; Birkenhead 17.1, Birmingham 11.0, Bradford 13.1, Hull 15.7, Leeds 18.6, Leicester 17.6, Liverpool 23.1, London 17.5, Manchester 21.8, Nottingham 17.0, Sheffield 17.1.

In Edinburgh 15.6; Glasgow 27.1; Dublin 2.6.

The meteorological record for week ending November 14th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole of the United States Signal Corps:—

Week ending	Barometer.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall.	
	Daily Mean.	Daily Mean.	Maximum.	Minimum.	7.00 A. M.	3.00 P. M.	11.00 P. M.	Daily Mean.	7.00 A. M.	3.00 P. M.	11.00 P. M.	7.00 A. M.	3.00 P. M.	11.00 P. M.	7.00 A. M.	3.00 P. M.	11.00 P. M.	Duration, Hrs. & Min.	Amount in Inches.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM NOVEMBER 14, 1885, TO NOVEMBER 20, 1885.

ELLEVY, F. W., assistant surgeon and captain. Sick leave of absence further extended six months on surgeon's certificate of disability. S. O. 263, A. G. O., November 14, 1885.

STRONG, NORTON, assistant surgeon and captain. Relieved from duty at Fort Union, N. M., and ordered for duty at Attending Surgeon's Headquarters, District of New Mexico, and post surgeon, Fort Marcy, N.M. S. O. 171 Department of Missouri, November 16, 1885.

EWING, C. B., assistant surgeon and first lieutenant. Now at Fort Leavenworth, Kansas, ordered to proceed to Fort Reno, Ind. Ter., and report to commanding officer for temporary duty in the field. S. O. 170 Department Missouri, November 15, 1885.

#### OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING NOVEMBER 21, 1885.

DEENAN, M. C., surgeon. Ordered to training ship "New Hampshire."

ATLICK, H., surgeon. Detached from training ship "New Hampshire," and wait orders.

FITTS, H. H., assistant surgeon. Ordered to appear before Examining Board preliminary to promotion.

REED, C. W., passed assistant surgeon. Granted sick leave for three months from November 20, 1885.

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE FOR THE WEEK ENDING NOVEMBER 11, 1885.

WHEELER, W. A., passed assistant surgeon. To proceed to Ontario, Canada, on special duty, November 11, 1885.

LEIGHTON, F. M., passed assistant surgeon. To proceed to Baltimore, Md., with steamer "Manhattan," and then rejoin station, November 12, 1885.

#### SOCIETY NOTICE.

MEETING OF AMERICAN PUBLIC HEALTH ASSOCIATION, WASHINGTON. We are requested to announce that tickets from Boston to Washington and return can be obtained for about \$14.00 at the office of the Pennsylvania R.R., Washington Street, Boston, on presentation of a certificate from the Secretary, Dr. Lyman A. Watson, Concord, N.H.

#### BOOKS AND PAMPHLETS RECEIVED.

The Embryo of Embryology in Parturition. By Henry O. Marey, A.M., M.D., Bo. Hon. (Reprint from Journal of American Medical Association, September 12, 1885.) Chicago: 1885.

L'Annee Medicale (Septembre-Août, 1885). Résumé des Progrès de la Médecine, des Sciences Médicales, Publiée sous la Direction de Dr. Boucaud, Paris, Librairie Plon, 1885.

Health Statistics of Women College Graduates. Report of a Special Committee of the Association of College Alumnae, Annie G. Hayes, Chairman, together with Statistical Tables collated by the Massachusetts Bureau of Statistics of Labor. Boston: 1885.

The Surgical Treatment of Cysts of the Pancreas. By N. Senn, M.D., of Milwaukee, Wis. (Reprint from the Journal of the American Medical Association, September 26 and October 3, 1885.) Chicago.

Book-Keeping Simplified. The Double-Entry System Briefly, Clearly, and Concisely Explained; with Valuable Rules and Tables for Counting-Room Use. By D. B. Waggener. Fourth Edition. Philadelphia: Charles R. Deacon, 1885.

The Diseases of Sedentary and Advanced Life. A Work for Medical and Lay-Readers. By J. Milner Fothergill, M.D., etc. New York: D. Appleton & Co., 1885.

Acne: Its Etiology, Pathology and Treatment. A Practical Treatise Based on the Study of One Thousand Five Hundred Cases of Sebaceous Disease. By L. Duncan Bulkley, M.D., etc. New York and London: G. B. Putnam's Sons, 1885.

A Formula Book. How to use Listerine. St. Louis: Lambert Pharmaceutical Co., 1885.

The Metric System and New Apothecaries' Weights and Measures. By Oscar Oldberg.

Note on a Form of Post-Neuralgia (Encephalotrophic or Cerebrasthenic) Insanity. By C. H. Hughes, M.D., St. Louis. (Reprint from the Alienist and Neurologist, October, 1885).

A Reply to a letter entitled Dr. Joseph Holt and Steam as a Disinfectant, Reprint from N. O. Medical and Surgical Journal, and Commercial Relations with Brazil as affected by Quarantine Regulations. Extracted from N. O. Press, October 20, 1885.

The Induction of Premature Labor in Certain Cases. By Walter Coles, M.D. (Reprint from St. Louis Courier of Medicine, November, 1885).

Report of Proceedings of the Illinois State Board of Health. Quarterly Meeting. Springfield: October 29, 30, 1885.

Inorganic Chemistry. By Edward Frankland, Ph.D., D.C.L., etc., and Francis R. Japp, M.A., Ph.D., etc. With Fifty-one Illustrations and a Plate. Philadelphia: Lea Brothers & Co., 1885.

Notes on the Classification, Diagnosis and Treatment of the Stages of Chronic Nasal Inflammation. By John N. MacKenzie, M.D., of Baltimore. (Reprint from Medical News, April 4, 1885).

A Contribution to the Pathological Histology of Acute and Chronic Goryza. By John N. MacKenzie, M.D. (Reprint from New York Medical Journal, August 22, 1885).

Some Observations on the Toxic Effects of Chrome on the Nose, Throat and Ear. By John N. MacKenzie, of Baltimore. Read May 8, 1884, at the American Medical Association.

Review of Hay Fever; its Etiology and Treatment, with an Appendix on Rose Cold. By Morell MacKenzie, M.D., London. (From the American Journal of the Medical Sciences, October, 1885).

Reflections on the Etiology of the Simple Inflammatory Affections of the Upper Air Passages. By John N. MacKenzie, M.D., of Baltimore. (Reprinted from the New York Medical Journal, September 12 and 19, 1885).

Aids to Surgery. By George Brown, M.R.C.S., L.S.A., Late Demonstrator of Anatomy at Westminster Hospital Medical School. New York and London: G. P. Putnam's Sons, 1885.

The Blot upon the Brain: Studies in History and Psychology. By William W. Ireland, M.D., Edin., etc. New York: G. P. Putnam's Sons, 1885.

Aid to Gynecology. By Alfred S. Gubb, L.R.C.P., M.R.C.S. New York and London: G. P. Putnam's Sons.

## Original Articles.

ELECTROLYSIS AND ITS THERAPEUTICAL APPLICATIONS.<sup>1</sup>

BY ROBERT AMORY, M.D.

ELECTROLYSIS is the result of a discharge of an electrical influence or action from one pole of an electrical cell to another in a fluid whereby a decomposition of the molecular combination occurs with a possible or probable reformation of a new combination. Faraday considered these terminals of an electrical circuit, as for instance, carbon and platinum, merely the doors through which the electrical force enters and leaves the fluid; he called these by the names of electrodes, and likened the path of this force to that of the terrestrial magnetism, namely, in the same direction with that of the apparent motion of the sun; where the current rose, as it were, from the carbon, the anode, and where it set the kathode or platinum; the decomposed particles, complicated though they may be, he called by the name of "*ions*," those which set towards the platinum the "*cat-ions*," those which went up against the electrical current (from West to East) and were the results of a chemical action at the anode — "*the anions*." The substance which was decomposed he called an *electrolyte* and the process *electrolysis*.

The ions act upon the fluid surrounding the electrodes. This phenomenon will occur unless the ions combine with the electrodes. As an illustration of this physical fact, chlorides become perchlorides and chlorates perchlorates at the anode. On the other hand, the secondary actions at the kathodes are those of reduction; thus if iodide of potassium in solution be subjected to electrolysis, one equivalent of iodine liberated at the anode will also have one equivalent of hydrate of potassium liberated at the kathode, showing that the potassium liberated from combination with the iodide has combined with some of the surrounding water. If chloride of ammonium be decomposed the chlorine liberated at the anode will react upon some of the remaining salt, giving free nitrogen and chloride of nitrogen. A rise of temperature favors the chemical decomposition and reaction and promotes at the same time rapid mixture of the ions with the solution. Consequently the higher the temperature the greater must be the current density or the size of the electrodes employed.

The application of electrolytic action upon abnormal growths in animal tissues is not so very recent, and its use in these many cases has been naturally limited by the fact that the surgeon's knife acts more surely and quickly; yet there are many of these abnormal growths for which excision by the knife is little used for obvious reasons. These might, for convenience, be divided into —

*First.* Skin marks, warts and other similar abnormalities which cover too much space, or are too vascular, or leave too distinct a scar when the knife is used.

*Second.* Many of these growths are deep-seated, or are within cavities of certain vital organs so that the risk of danger to surrounding parts or incomplete removal makes the surgeon hesitate to operate. Of this class are uterine fibroids, glandular growths, and

perhaps might be added, though irrelative to this class, aneurisms and emboli.

*Third.* Adventitious growths which are too small and too numerous to be removed without more blemishing effects than the original trouble. Of this class are small wens in the scalp or skin and facial hairs on women's faces.

Now let us presuppose some practical theory to explain the result of electrolysis in abnormal vascular growths, whose size is most certainly reduced by its application. I think that it is most generally admitted that these latter undergo diminution of extent from the electrolytic puncture, and that little, if any, inflammation of the surrounding tissue supervenes. If a needle be plunged into tissue containing living blood, and the needle be withdrawn, a small amount of blood appears at the puncture; if, however, a moderate current of high tension be passed through the needle into the puncture, no blood will appear on withdrawal of the needle, provided the latter be connected with the negative pole, or kathode, or hydrogen pole; if, on the contrary, the needle be connected with anode or positive pole, on which oxygen collects in the voltmeter, blood will follow its withdrawal. To illustrate, I prick my finger point with the needle and blood flows, so also will it flow if the current from the positive terminal be conducted into the needle, while if the hydrogen or negative pole be used no blood follows the puncture. Now observe that I have instanced the use of a current of moderate or high intensity, or density, if you prefer the term. It would seem to be a matter of simple deduction to believe that if the vascular supply be diminished in an abnormal growth, and especially if a portion of the tissue is destroyed by mechanical or physical means, that the growth will become smaller and finally be replaced by a lower order of tissue formation. In fact, this has been successfully accomplished by surgeons tying arteries that supply large growths with blood supply, though this has sometimes been followed by disastrous consequences. Examples of this character are shown in cases of enlargement of the thyroid gland or body, especially of the form known as exophthalmous goitre (as it is sometimes called), familiarly known as Grave's disease. Fortunately these cases are not frequently met with in this part of the country. In my clinical experience I have had five of them under treatment, in all of which I first pursued a thorough course of treatment by iodide of potassium in large doses, but without any effect upon the glandular enlargement; in two of these digitalis was tried, with similar want of success. In two I tried the constant current applied over the course of the sympathetic nerve and the ganglia of the neck, and at the condyle of the jaw, and also the faradic or interrupted current from an induction coil, but with no obvious advantage. In two of them I used the electrolytic needle. One of these was considerably benefited by the current from a dynamo-machine of high tension, and small internal resistance; in this case the negative pole was passed through a gilt needle and enlargement was reduced to one-half of its size, and has been no larger for four years since; the exophthalmos was also considerably reduced. The current in this case produced so much pain that I ceased treatment after about twenty sittings of twenty minutes each.

The fifth case was very striking and was carefully examined last fall by Dr. J. C. Warren, before I began any treatment at all; he also saw the case several

<sup>1</sup> Extracts from a communication to the Suffolk District Medical Society, October 31, 1885.

times during the treatment by electrolysis. When first seen by me a measurement around the whole neck at the upper margin of the enlargement showed thirty-six centimetres (36 cm.), January, 1885. At this time she went into the country for six weeks and took regularly and daily doses of iodide of potassium, from ten grains gradually increasing to twenty grains and forty grains, until the local effects of coryza and indigestion were so disagreeable that she reduced the daily amount to fifteen grains. On March 26th she returned to Boston. On examination the measurements of the neck were nearly of the same dimensions as when I first saw her; namely, 36 cm. at the upper margin, 39 cm. along the middle line of the swelling, and 40 cm. at the lower margin. Digital and ocular examination of the tumor failed to show any cysts or irregularity of the swelling, except to suggest an isthmus and two alae, as is often seen in these cases. After the pressure exerted by persistent digital examination the skin would redden and the tumor enlarge. I introduced the gold needles, which are here shown, (by Stubb's gauge, varying from size from No. 55 down to No. 60, and the smallest measuring .0029 inch) through the skin and into the vascular swelling about half an inch deep; they were then connected with the hydrogen or negative pole (kathode), the other pole being attached to a piece of carbon covered with wet chamois skin being held in the hand; gradually the current was increased to the full strength of this battery, namely, twenty-four cells (Gaiiffe's modified Leclanché cells). The pain where the needles were in contact with the skin was sharp but not unbearable, and soon gave place to a sense of numbness. The current was applied for twenty minutes' duration. This same application was repeated on the 30th, and again on May 10th; after the latter sitting the measurements taken around the neck and as nearly as possible in lines similar to the first time showed a diminution of 25 mm. at the upper margin, 20 mm. at the middle, and 40 mm. at the lower margin. After seven sittings (on April 17th) on which date she was exhibited to a class at the hospital by Dr. Warren and subjected to pretty considerable handling, the tumor had increased somewhat in thickness, though its marginal borders were narrower in all directions; the measurements taken on this date were 35 cm. at upper margin and 37 cm. at lowest margin. I regret that I did not take the measurements in extenso, to have judged of the improvement in the marginal limit; but it should be remarked, the perceptible diminution, as seen by inspection, was very great; though the circular measurements around the whole neck do not correspond with the improvement in the thickness of the vascular swelling, which were apparent to the eye; it might be readily understood that as the margins were narrowing the measurements would naturally be taken in places which were different from previous examinations. I must own that I had not expected such rapid improvement, and consequently did not measure the diameters of the tumor, nor had I expected to present the history of the case to a medical meeting. The 26th of May was the last application of electricity, fourteen sittings in all, and on the 30th of May the tumor had been so reduced that I advised waiting until after the summer season before resuming the electrical applications. I saw her again, and for the last time, on the 20th of June. On this date the measurements of the diameters were about 5 cm. on the

horizontal line, and the swelling had resolved itself into two ovoid-shaped alae and an isthmus, that on the right measuring about 2 cm., that on the left a little less than 2 cm., and the isthmus making up the balance; the shape of the two alae was ovoid, the longest axis being on the horizontal line. The neck which had been thick and distorted at the first visit was then long and thin, and there was no protusion of the eyeball. The irregular and tumultuous pulsations of the heart which are common in "Grave's disease" were, however, pretty well marked. I prescribed digitalis, hoping that it would improve this symptom. She went home to Nova Scotia, and I can therefore only give the report of her condition in a letter received from her sister last month, and in one written by herself, October 21st.<sup>2</sup>

In the first letter, dated September 14, her sister writes: "I found M. not very well, but she is improving. She gets tired very easily, and her limbs feel *shaky* when she walks but a short distance. I think Dr. Amory would be very much pleased could he see her neck now. It has become very much smaller even in the last weeks, and we are all so happy about it. She perspires very freely, especially her head, her hair being damp all the time."

In the second letter from herself, dated October 21, 1885, she writes: "There is still a little swelling in my throat, which you can see clearly in one of the proofs, but my doctor who examined me soon after I came home, and again this week, says that now it is less than half the size it was when he first saw it, and I know you would be very much pleased with the improvement could you see it yourself. I have been gaining in strength very rapidly ever since the weather has turned colder."

The case of M. is that of a parenchymatous bronchocle without cysts, which was vascular and growing larger, and the object of treatment by electrolysis was to reduce the size of the growth, which had already so pressed upon the larynx as to cause huskiness, and at times complete loss of the voice, besides being accompanied also by dyspnea. The growth was evidently encapsulated, for it was difficult to push through this envelope the gold needles, which you may see are both stout and sharp-pointed, and after it had been penetrated it required some caution to prevent too deep a penetration, on account of the soft tissue enclosed. Once or twice a drop of black venous blood would ooze from the puncture of the needle, but only after one application was there enough blood to spot the collar after the first drop had been wiped off. At no time, except as before stated, did any secretion or fluid exude from a puncture.

The constitutional symptoms in the above case were three, exophthalmos, the parenchymatous goitre and the cardiac symptoms. Only one of these symptoms was attacked, namely, the enlargement of the thyroid body. With the reduction of this enlargement the protuberance of the eyeballs disappeared. The third symptom, increased frequency, irregularity and tumultuous pulsations of the heart, though greatly improved, persisted after the reduction of the enlargement of the thyroid body. When the heart was examined, both before and after treatment, there were anemic sounds heard, but once or twice during treatment they could not be distinguished. There were also other signs of

<sup>2</sup> Three photographic portraits of the patient's present appearance were shown.

anæmia besides this, as, for example, the color of the pale mucous surfaces, frequent and pale menstrual flow, inappetence, restlessness and muscular languor, also shortness of breath after exertion. With her letter, dated October 21st, which I read to you, she sent these three photographs, which shows that very little of the vascular swelling remains.

The next series of cases which I present to your respectful consideration, are the treatment by electrolysis of superfluous hairs on the face of women, of enlarged sebaceous glands or wens, and of hair moles and warts. The treatment here being applied to the cutaneous structure naturally is followed by more pain, and consequently the battery strength cannot be used to the same extent as when applied to deeper tissues.

Without going into unnecessary detailed description of the hair follicle it is sufficient for our purpose to

THE HAIR AND HAIR FOLLICLE.  
(From Duhring's Diseases of the Skin.)

A, Shaft of Hair; B, Root of Hair; C, Cuticle of Hair; D, Sebaceous substance of Hair; E, Papilla of Hair.

state that the hair emerges from its follicle and depends for its nutrition upon the papilla, which is situated at the bottom of the hair follicle, and derives its nourishment from the arterial supply to this papilla, which anastomoses, and finally becomes the venous outlet. The sebaceous glands are found wherever the hair abounds, and these, as a rule, connect with the hair follicles, and occasionally when small, are a sort of sacculated bulging from these follicles. Now if the hydrogen-forming pole be passed into the sebaceous follicle, and the electrical circuit be set up in the subject, there will appear a series of bubbles at this hydrogen-forming terminal (negative pole), and white minute drops of emulsion, like that noticed in the saponification of fats. We may prolong the action for several minutes, but unless we grope round with the electrolytic needle until the papilla is transfixed, we may pull gently on the hair which is nearest this sebaceous follicle, but in no case will it readily leave its hair bulb unless force be used, and in that case it will

surely grow again. Yet, if the operator is sufficiently skilful and finds some indefinite place out of which the saponification may or may not exude, he will, by gently pulling on the hair into whose follicle he has penetrated with his electric negative terminal, with the very lightest traction extract the hair, or better still, the hair may fall out without traction. In either of these latter cases the hair will not grow again, as the papilla in the follicle is destroyed.

On examination into the cause of this successful treatment of epilation, you must know that two-thirds of the sebaceous substance secreted by these glands is composed of water and the remaining one-third is chiefly fats, extractive and other albuminous materials and some earthy salts. Fat is essentially a hydrocarbon (free from oxygen), and hence if we pass a chemical or electrolytic current through the fatty secretion in the sebaceous gland and see bubbles of gas forming upon the pole by which the current passes out of the circuit it might be assumed that the fatty matters are decomposed by the escape of hydrogen. However plausible this explanation may seem, it does not answer all the conditions. I have seen a most liberal saponification follow the introduction of the electrolytic needle into a sebaceous gland adjacent to a hair on the skin, but the hair not only did not fall out or come out by gentle traction, but worse than this, in a few weeks it would grow again and apparently stronger and thicker than before. If then with more care than first was used, I would extend the hair and follow along its cylinder until I touched the bottom of its own follicle and applied there the negative terminal the hair would entirely come out, and would not reappear. In order to destroy the hair it is not essential to cause the secretion of sebaceous matter nor to penetrate the sebaceous follicle. Penetration of the hair follicle and the papilla of the hair with the electrolytic needle will destroy the life of the hair, provided the needle be the cathodal terminal of the battery. If the other pole is connected the positive current will singe the hair within the follicle but will not destroy its life; in fact it will stimulate its growth. A true destruction to the living tissue follows the presence of the hydrogen terminal, and the cicatricial tissue which replace the hair sac leaves but a small scar. Consequently it is essential, to avoid large scars, to use as fine a needle as will accomplish this destruction. If a needle be used which is made from metal offering a resistance to the electrical current, it should be remembered that the resistance is increased by that of the body, which is nearly 2,500 ohms. It should be remarked in this connection that the alopecia following scorb主 is probably the result of inflammation and destruction of the pilous follicle, and will be consistent with the same hypothesis in which it is fair to assume a destruction of the papilla from destruction of tissue and obliteration of the hair follicle; disease in the latter instance accomplishing what electrolysis is forced to do by treatment. I have here a series of photographs from a very exaggerated form of hair-growth in a woman, which in fact is as strong as we see in the beard of male adolescence. This case has been under treatment during four months last spring and one month this fall. I have removed 3,000 facial hairs, of which five per cent. grew a second time, because the papilla were not destroyed. The series shows not only the gradual decrease in the hairs on the face, but in some of them the results of such

heroic treatment is seen in the *recent* scars which are prettily liberally distributed upon the chin. Yet by examining carefully with a magnifying glass the photograph taken on September 27th, you will observe that though the scars when recent are quite distinct, three months' interval effaces most of them, the new skin showing not much induration, but in a few months rather an exaggerated whiteness where the follicle had been destroyed, in some cases shining like the skin of a man's bald head. In these other photographs taken after epilation, either complete or incomplete, the skin-marks may be seen indistinctly, and you may observe also that the photographs are taken on an exaggerated scale, as may be seen from the effects of coarseness and detail of the skin as well as the largeness of the freckles which artistic photographers seek rather to obliterate, since they are not seen in their pictures. In one of these photographs, marked M., of a young girl's face from whose skin about five hundred hairs have been removed, though the freckles are quite apparent the marks of the needle can scarcely be made out. In another, marked O., may be seen the scar left from the removal of a hair mole on the cheek; in this case the mole was as large as an ordinary white bean, from which hung twenty-six to thirty long coarse hairs and nearly as many fine hairs. These were removed by electrolysis in August, 1881, and the mole has, as you may see, been entirely removed, and the scar is only half the size of a split dried pea. None of the hairs have ever reappeared, as you may see in the photograph, which was taken only three days ago.

The method of procedure is very simple, and though it may be known to some of you, others may be desirous of a description.

After inspecting carefully where a certain hair protrudes from the skin, the needle, which I will especially mention later on, is passed along the hair shaft into the hair follicle, and then connected with the negative or hydrogen terminal of a battery, where it is turned and twisted in many directions but without using sufficient force to push in through the bottom of the sac. If penetration is effected through a sebaceous gland, the sebaceous matter will bubble and boil out in a sort of soap suds; if you are fortunate enough to have struck the papilla, twenty or thirty seconds' duration of the circuit current, which is established by the moistened positive terminal applied to any portion of the body, prettily the skin of the hand, will suffice to destroy the hair, which will follow a gentle traction with a pair of hair forceps.

These forceps I have had constructed of a pattern which I show you; they have the advantage of a curvature at the point to allow of the more readily groping with the needle for the hair shaft. If, as is more often the case, you have missed the papilla on your first introduction of the needle, you must grope around until you find the hair loosened, when again gentle traction will loosen and remove it.

Unfortunately, there are but few guides which will point out exactly the position of the papilla. A few of these are important. If the hair has never been extracted from the follicle, following down its axis from where it protrudes from the follicular outlet of the skin will often suggest its hair; if, on the contrary, the hair has been extracted, and more than once, the seat of the papilla is not in the direct axis, but to one or the other of the two sides, and in such cases, the operator will find the papilla more readily by bending

the needle point in a sort of hook or at right angles to its length. You may be sure of two things, first, that if the electrical current is good, and the conductivity of your rheophores and needle in good order, twenty seconds is sufficient to destroy each hair growth; but under the best of circumstances it will take an hour of constant work to remove from forty to fifty hairs.

As electrolysis is becoming one of the fashionable agents in the cure of diseases, it may not be amiss for me to state that many physicians may use the method without being familiar with certain matters which it is important for us to know, and which are well known to physicists. The practical bearing upon the question before us will be apparent, and it may be observed that through this ignorance, already some physicians have been led to underrate a treatment which, in its proper place, will become an important factor to relieve forms of disease which can hardly be so well cared for in other ways. To illustrate, physicians are using to-day certain terminals and batteries which are a hindrance to the very object they wish to obtain. Among these are iron wire, or other poor conductors, and batteries of a deficient electro-motive force. You may remember in the early part of this communication I called your attention to the fact that iron and steel are poor electrolytic conductors. I grant that annealing the iron makes it a better conductor, but even then it does its work in a more or less difficult way. According to Jenkin's tables

The resistance of annealed iron is	.125
" " platinum	.116
" " gold	.026
" " annealed "	.025
" " silver	.019
" " copper	.017

In fact, the resistance of annealed iron is, therefore, nearly five times as great as that of gold, and that of platinum four times more than that of gold. When you remember also that Faraday's experiments showed that iron was converted into a peroxide from an oxide which is hardly a conductor of electricity, you will see how much smaller an electrolyzing agent we get from this metal. In view of the fact that the resistance to electrical conductivity furnished by the human body is so much higher than that of most metallic electrodes, practically the question of the latter is not of great consequence. On the other hand the high internal resistance of a battery is important, and the varying strength of a battery used for a sitting of an hour, offers a serious objection to its selection, because owing to the polarization of its elements, the current becomes too weak to effect a sufficient electrolysis.

It is generally supposed that an electric battery is a simple and constant thing, and that one form is as good as another for medical uses. No greater mistake can be made in connection with this matter of electrolysis. I have used many batteries, Daniells' cells, Leclanché cells, Dynamo machines, chloride-of-silver batteries, and many other forms. In the commercial uses of electricity, no battery has yet been found that perfectly answers the purpose, yet in medicine, physicians seem content with apparatus that the electrician long ago has discarded. Improvements are constantly being made in electrical cells, and for convenience and portability for electrolytic uses, probably that of Gaiffe has up to this time, stood best. Of such a battery I present this one. Its work for two hours keeps up in a pretty uniform way and with fairly constant strength; and in conclusion, I will describe this and another modi-

fication of the Leclanché pattern, as well as the means we have for testing the electro-motive force, and the subsidiary apparatus for medical uses of electrolysis.

Gaiffe's modified Leclanché cell battery with twenty-four cells is contained in this portable box, which is so arranged that any two of the cells may be used at pleasure without disturbing any of the others. This is accomplished by the use of what is called a Dial Collector, by which every two cells are short connected by a wire, leaving the others out of the circuit. This cell is formed of carbon and sesquioxide of iron for one element and zinc for the other; the exciting fluid is water, into which is thrown one-fifth of its weight of zinc chloride, which must be neutral to test paper, and free from lead. In this cell the elements are secondarily depolarized so that the electrical action is quite constant for three or four hours of continuous service. Its action is unlimited, provided it is not overworked, and that the zinc is replaced when used up. This battery has been in pretty constant use for two years. Its electromotive force, in the size used here, is about three-tenths of a Volt. A Volt is equal to the electro-motive force which is furnished by about one Daniell's cell freshly charged,<sup>2</sup> while an Ampère is equivalent to the strength furnished by an electro-motive force of one Volt passing through a resistance equal to one Ohm.<sup>3</sup> It may be seen, therefore, that the quantity (as it is termed) furnished by Gaiffe's is small, owing to its enormous internal resistance. An instrument called a Voltmeter, applied to this battery, shows that the full strength will decompose in a minute of time twenty-three cubic millimeters of combined gases from a one per cent. solution of sulphuric acid and water, which is equal to two milliamperes (one-thousandth of an ampère).

Another battery of the modified Leclanché cell, of which these two are a pattern, is made by Holtzer of Brookline, on a mechanical principle very similar to that of Gaiffe's, though the exciting fluid is a solution of ammonium chloride in water; but in this form which you see, the elements are large and offer a wider surface to a larger body of water. The internal resistance of this form of cell is very low, the tension is high and the quantity of the current is large. The action of this battery is very constant, and its power of decomposing water by electrolysis is very good, twelve of these cells decomposing one hundred and sixteen cubic millimeters of the combined gases from the same solution, and is, therefore, equal in power to ten milliamperes, and has three times the electrolyzing power of the Gaiffe battery. Its work on the human tissues might be compared to that of a sharp knife as compared with that of a dull knife when using Gaiffe's battery. The consequence to the patient will be that less formidable scars and more certain destruction to the pilous follicle will result from its use in preference to other batteries of feeble power.

The instruments used for the purpose of epilation are an insulated needle-holder and a fine needle. I had hoped to go more fully in this application of electrolysis as a therapeutical measure, especially for the treatment of enlarged sebaceous sacs, or so-called wens, which are more readily cured by this than by any other surgical method. Its application to the cure of acne in its

varied forms is also wonderfully successful. I have, however, trespassed on your patience so long that I will defer further details for more general publication in some other channel, in a memoir which I am preparing for the general practitioner.

## Hospital Practice and Clinical Memoranda.

### REMOVAL OF A TUMOR OF THE LEFT THIGH ADHERENT TO THE SCIATIC NERVE, WITH EXCISION OF A PORTION OF THE NERVE.<sup>1</sup>

REPORTED BY WM. B. LITTLE, M.D.,

Late House Officer of the Lyman Hospital.

Mrs. H., age twenty-five, occupation button-hole operator, was admitted into the Lyman Hospital May 12, 1885, having previously been seen by Dr. J. S. Emerson. She presented a large, firm tumor, on the posterior aspect of the left thigh, just above the popliteal space, which had been growing for a year and a half.

It first manifested itself by a dull ache along the thigh, followed by sharp lancinating pains upwards, one spot being very tender. Patient had no inconvenience while walking, but sitting caused severe pain. She had felt some anxiety about the tumor, thinking it might be incurable. She had been immoderately fond of roller-skating, and of feats of high kicking, in which latter trials she had beaten all her rivals. Her family history was good, except that her mother had had large fatty tumors on back, thighs and arms. The patient was first advised to see Dr. C. B. Porter, of Boston, who advised removal of the growth. An exploratory aspiration of the tumor was made on the 13th of May, but no fluid was found. On the next day, May 14th, the patient was etherized and the operation for removal was performed by Dr. Emerson. An Es-march's bandage being applied, an incision seven and a half inches long was made on the posterior aspect of the thigh, directly over the tumor which was closely adherent to the surrounding tissue. These were detached by dull dissection until the pedicle was reached. This was found closely connected with and apparently incorporated in the sciatic nerve to the extent of about an inch. The tumor had grown backwards and downwards, and found its way in under the nerve, so that the nerve lay in a groove on the upper surface of it. It was impossible to dissect off the attached portion and it was decided to resect the nerve to the extent of an inch and a half, and thus remove all the diseased structure. The cut end of the nerves were approximated and retained in position by three catgut sutures. All hemorrhage was arrested, and a drainage tube put into the wound which was then closed by sutures and strips of plaster, the whole being covered by a modified Lister dressing, with iodoform gauze as a protection. The leg was placed at nearly a right angle with the thigh and held by bandages. On the evening of the second day from the operation the temperature rose to 104°. The dressing was removed, the tube thoroughly syringed out with carbolic water and the wound redressed. Each night thereafter the temperature declined one degree till normal was reached, the wound closing with very little suppuration. Patient was in good spirits, complained

<sup>1</sup> Five to ten per cent. loss.

<sup>2</sup> The Ohm is about equal in resistance to 85 meters of pure copper wire of one millimeter diameter at a degree Centigrade.

<sup>3</sup> Read before the Essex South District Medical Society.

of but little pain and had an excellent appetite. She was frequently tested as to sensation in the foot and leg, which was impaired though not wholly lost. If the great toe was touched she thought for a time that it was the little toe, and vice versa. It was supposed that the cut ends of the nerve in some way became twisted so that the sensation travelling up the nerve fibres on the inside of the leg from the big toe beyond the line of section crossed to the outside, and vice versa.

On the 28th of May extension was begun, a movement of two or three inches being accomplished at a time. Her condition remained good till the 25th of June, when she had some slight febrile disturbance lasting but a day or two. She was discharged the third of July, and then had impaired sensation below the knee. There was no motion except with the thigh. She had no ache or pain when sitting, and no tenderness on the thigh. She stood upon the foot for the first time on the 26th of July, but the knee had a tendency to come forward. From this time till the 11th of August she used a cane to assist her in walking. On the 12th of August she walked to the doctor's office and back to her residence without any assistance. At present there is a slight limp in walking, but she affirms the whole limb to be growing stronger each day. She can go down stairs easily, but has some difficulty in getting up stairs. On the outside of the foot there is no feeling whatever, but on the inside and on both the inside and outside of the leg she says the feeling is as natural as ever, but the foot is completely powerless. Within the last few weeks she has twice noticed a sensation of itching on the sole of her foot. For the last three weeks she has followed her occupation without any discomfort.

The tumor was ovoid in shape, twelve inches in its longest circumference, and weighed eleven ounces. The pedicle was firm and fibrous. It was a sarcomatous tumor whose cells were embryonic in character and embedded in connective tissue. As sarcomata originate invariably in the connective tissue structure, this tumor must have found its origin in the neuroglia of the nerve. On section, the tumor presented a bony substance about one and one-half inches in diameter encased in a softer tissue to the depth of about an inch. Ziegler says, "sarcomatous tissue may easily be the result of proliferation of the cartilage of a chondroma or the fibrous tissue of a fibroma, and conversely sarcomatous tissue;" may equally well be transformed partially into osseous tissue, and the growth of this tumor seems to confirm the latter statement.

The resection of the nerve; the peculiarity of sensation experienced by the patient during her convalescence; the probable origin of a sarcomatous growth in the neuroglia of a nerve; its growth and development to the formation of bone; were all features of unusual interest.

Two wills were lately offered for probate in Salem, Mass., one made in 1807 and the other in 1802. The testators died respectively in 1822 and 1812. Where the wills have been during this time is not explained. Both wills were allowed by the Probate court. The testimony as to the genuineness of the signatures of testators and witnesses was all offered of course by very aged witnesses, some of them being upward of eighty years old. The court, however, evidently had confidence in the reliability of their memory.

## Reports of Societies.

### PROCEEDINGS OF THE SUFFOLK DISTRICT MEDICAL SOCIETY.

CHARLES M. GREEN, M.D., SECRETARY.

OCTOBER 31st, 1885, the President, DR. GEORGE B. SHATTUCK, in the chair.

DR. ROBERT AMORY read a paper on

#### ELECTROLYSIS AND ITS THERAPEUTICAL APPLICATIONS.<sup>1</sup>

DR. J. C. WHITE said that he had operated for hypertrichosis by electrolysis in many cases in the last four or five years. According to his experience, there will be a slight amount of scar formation in a certain proportion of the cases, not dependent upon the degree of inflammation produced by the operation, which is inevitable in some measure in every case, and not to be foretold in any instance. The scars are, however, when a very fine needle is employed, only minute, cup-like depressions at the mouth of the follicles destroyed, and are much more noticeable in brunettes than in blondes. He knew no way to prevent this result in skins thus disposed. The slight deformity thus produced is, however, in no way comparable to that of the pre-existing hair growth. Contiguous follicles should never be operated upon simultaneously. A certain proportion of the hairs operated upon, also return, even with the greatest possible care, about one in eight or ten on the average, which have to be subsequently removed. Eventually the operation was always successful. He generally used the very finest jeweller's broach, but occasionally the iridio-platinum needle of Dr. Hardaway, of St. Louis, who first applied the operation to hypertrichosis. The needle is passed directly down by the side of the hair until it reaches the hair papilla, a point readily recognized by the experienced hand. The operation has nothing to do with the sebaceous glands, and the "foam" which always issues at the side of the needle is the escaping hydrogen generated in the albuminous fluid. The kind of battery he considered unimportant, and this was the unanimous opinion of dermatologists expressed during a discussion of the operation at the recent meeting of the American Dermatological Association. He had generally employed a chloride-of-silver battery, which required refilling but once a year, although used nearly daily. He thought that the treatment of vascular growths by electrolysis was rarely successful unless very superficial.

DR. MORRIS PRINCE said that he had been fortunate in not seeing much scar formation following the process, though when he first began to use electrolysis more scars resulted than did later. This improvement in the results was probably due to greater experience. To avoid scars it is desirable to observe three precautions, namely: not to remove at the same sitting hairs that are situated close together; not to insert the needle too deep—that is, below the hair follicle; and third, not to use too strong currents, even though more hairs thereby returned. If this happened, the operation could easily be repeated, and pain and soreness of the skin largely avoided. He had found that different parts of the face bore electrolysis differently.

In a case under his care at present, for example, the strongest currents were borne upon the side of the

<sup>1</sup> Extracts from this communication appear on page 529.

face without ill effects, without scar formation and with scarcely any secondary inflammation; whereas, even weak currents, applied under the chin were followed by local inflammation and scars, unless great care was exercised. These scars, however, upon which much stress has been laid, are not conspicuous, but fine points, hardly noticeable, infinitely preferable to the hairs.

As to apparatus, he used for a needle-holder simply a perforated laryngoscope handle, through which the battery wire was seen. This was light, allowing delicacy of touch, and better than any he had seen. As to batteries, he agreed with Dr. White that one battery was as good as another—that is, of the ordinary medical galvanic batteries. He had used gravity, zinc and carbon, and chloride-of-silver batteries and could not see any difference in the results. One may have to use more cells of one battery than of another, but only a weak current is required, and as long as one have enough cells, it makes no matter. For a needle, he, also, used the ordinary fine round goldsmith's broach. It answered every purpose. After heating it at the shank it could be bent to any desired shape. Though theoretically one battery or one kind of needle might possibly be better than another, practically, with the apparatus just mentioned, electrolysis could be perfectly performed, the hair readily destroyed, and he could not see what more was needed.

Dr. AMORY said there was a great difference in the efficiency of different batteries, and he thought the chloride-of-silver battery was unreliable, which was the only battery he believed Dr. White used, on account of the difficulty of making with this battery the electric discharge constant and of uniform electromotive force. Makers of electrical medical batteries, like Gaiffe in Paris, and Stohrer in Dresden, as also at the officina Galileo in Florence, had given up the attempt to make this form of battery (*De la Rôve*), on account of its unsatisfactory use in practice. He believed that more formidable scars followed the use of the watch-maker's iron broach (even when the temper of the steel was drawn) than was observed after the use of his own gold, or of iridium-platinum alloy needles; whether due to the use of a better battery—or rather, a battery of higher electro-motive force and of uniform current, strength and resistance—or to the improved conductivity of his gold needles, or to both causes, he thought the return of hairy growth occurred less often in his experience than in that mentioned by Dr. White from his experience: in two instances Dr. Amory recalled the fact that not one hair of about fifty which he removed over a year ago at the first sitting has ever reappeared. Dr. Amory further stated that by pricking cocaine oleate (normal strength 52 per cent. of the alkaloid) into the skin of his patients, he found the same patient could tolerate a larger number of cells and for a longer period of time than without its use. Subsequent skin inflammation was less and the scars were more superficial and smaller, probably on account of the more rapid destruction of the hair papilla.

Dr. H. L. BOWDITCH asked the reader if electrolysis had proved of any value in the treatment of aortic aneurism.

Dr. AMORY replied that in Hotel Dieu in Paris, electrolysis was used in the treatment of aneurisms of large vessels, but not in aneurism of the aorta.

THE PRESIDENT remarked that in 1877, McCall

Anderson of Glasgow reported three cases in which electrolysis was employed in the treatment of aortic aneurism, in two successfully, in one unsuccessfully. Dr. John Duncan of Edinburgh had previously had two unsuccessful cases.

Dr. A. C. GARRATT remarked that in connection with this subject of electrolysis, he wished to announce to the society the important fact that a new primary battery had recently been invented in this city that must hereafter greatly facilitate and make more efficient the medical and surgical uses of electricity. The peculiar excellence and superiority of this new battery consists in its cheapness, power and *endurance*. That is, to provide and maintain a constant current of high tension and great quantity without flagging, even in the most lengthy applications. While doing a hard and prolonged work, it keeps in order and holds its strength for many months together and this without lifting out of the fluid any of its parts.

By actual tests this battery has proved to be able to do from five to seven times more work, as in heating a platinum knife or wire red hot, or sustaining an electric light, than any bichromate of potash, or other battery known. There is no bichromate of potash in it. It is named after the inventors, the Kauffner and Goldener battery. He did not call the attention of the profession to this new battery because he had any immediate pecuniary or commercial interest in it, but because, from his standpoint he saw its importance as an aid in therapeutics, and wished to have the honor of first bringing this wonderful battery to the notice of this society and through it to the medical world.

This new battery was first brought to his notice about three months ago. Soon after that a single cell, arranged as a two-fluid battery, for it can also be arranged as a single fluid plunger battery, was set up in a back room with wires twenty feet long connecting it with several helices in his office, some of which were very long coils and offered greater resistance; it has worked any or all of them together daily and has remained entirely untouched days and nights all this time and is still in as good power now as at first. On State Street, by means of a few of these battery elements, electric incandescent lamps at full candle-power were maintained for over two hundred hours, without renewal of solution or other element of the battery, and no potasse-chrome-alum crystals formed to hinder or stop its action.

#### BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

E. M. BUCKINGHAM, M.D., SECRETARY.

NOVEMBER 9th, 1885, the President, Dr. F. W. DRAVER, in the Chair.

Dr. A. L. MASON read a paper entitled

TYPHOID FEVER AT THE BOSTON CITY HOSPITAL IN 1884—1885: WITH REMARKS ON THE USE OF ANTHRYNE.

He said that since January 1st, 1884, 112 cases of typhoid had entered the hospital, with 17 deaths, or 10.7 per cent. This included all who entered moribund, and excluded all cases of mild, doubtful fever and febricula. The number of cases in the city at large during the same period, so far as reported to the Board of Health, had been about 1,300 with 288 deaths, or

per cent. One-third of all the cases reported to the authorities were treated at the City Hospital, and the mortality among the remaining two-thirds might be regarded as high if all cases were returned. But, as this is a recent requirement of the Board of Health, it is probable that many of the milder cases escape registration, thus increasing the apparent proportion of deaths.

The mortality from typhoid in Boston was not great as compared with that from other diseases. Last year, for instance, there were more deaths from whooping-cough; twice as many from diphtheria, a comparatively new disease in this community; and six times as many from pneumonia.

It was sometimes said that typhoid fever had lost its former virulence. How far epidemic diseases, of periodic recurrence, were preventable by improved sanitary conditions was not known; but it was probable that any immunity resulting from milder visitations of this disease was due chiefly to the energetic measures of the Board of Health.

The interesting report on Typhoid Fever at the City Hospital, by Dr. C. Ellery Stedman, published in 1882, in the third series of Hospital Reports, showed the mortality rate for fifteen years to have been 17.3 per cent.; varying from 12 per cent. in 1872 to 21 per cent. in 1879, when only 70 cases were received. In 1881 the rate was 11 per cent.; in 1882-3, it was not known to the reader; in 1884 it was 9 per cent. in 254 cases; and it had been 12.2 per cent. in 188 cases thus far in 1885. Therefore it appeared that the hospital death-rate was likely to be somewhat lower than in the last decade, and lower than that which prevailed in the city at large.

The hospital records threw little light on the causes of typhoid. The number of cases had increased with the growth of the city. Many patients entered too sick to give an account of themselves. Sixty-five per cent. came in August, September and October. This year twice as many entered in August as in the same month in 1884; and in October, 1884, twice as many as during the October just past. They were widely scattered, many coming from the crowded districts, where all diseases thrive; many also from the suburban wards; some fresh from the country. Occasionally one was found who had been drinking water from a well, possibly contaminated. But few cases could be traced to any specific source. They came with the season. Isolated instances occurred in which a *de quatuor* origin was suggested.

However various the sources of infection might be, contagion played a small part in the hospital. Among the large number of nurses and attendants, most of them at very susceptible ages, there had been no death from typhoid for several years; and but seven cases, all in females, had occurred in the past two years. No house-physician had contracted the disease since the opening of the hospital, twenty-one years ago. Disinfection of stools with chloride of zinc was enforced.

Of these 112 cases, about 500 got well without much assistance beyond careful and abundant feeding, chiefly with milk, intelligent nursing at the hands of the members of the City Hospital Training School, cold-sponging, and such occasional medication as was required.

The others were severe cases, many entering at late periods of the disease, some in a hopeless condition. In treating them, no routine method was adopted by

the different physicians of the hospital staff. But, as free stimulation and some mode of reducing the fever were generally adopted, the reader offered a few remarks on those subjects, especially on the effect of alcohol in large doses, and of antipyrine.

He reported several critical cases in which brandy to the extent of a pint and a half daily had been administered for many days, in one instance for more than two weeks. A few such cases got well, either because of, or in spite of the extreme stimulation. The absence of the ordinary effects of alcohol in health was noticed, but the reader doubted the beneficial effects upon the heart and nervous system of long continued saturation without chance for elimination. Although it was difficult to fix a limit beyond which brandy ceased to be useful in typhoid, he thought that eight or ten ounces daily would in almost all prolonged critical cases have a better effect than double or treble the quantity.

The action of antipyrine, to which Dr. G. B. Shattuck had called attention in a report last year, had been further observed by the physicians of the Hospital in about one hundred cases of typhoid fever.

This drug had been used, in single or continuous doses, in most cases which had a temperature above 103° F. without decided remissions. Doses of eight, ten, fifteen, twenty, or thirty grains had rarely failed to reduce the fever from three to five degrees within an hour of their administration, the effect of the dose continuing from three to six hours. One drachm daily was seldom exceeded. A child five years old was treated successfully with doses of eight grains, and in other children between seven and twelve years of age, fifteen grains had usually produced rapid defervescence without ill effects.

The evening exacerbations were modified, giving quieter nights, and sometimes a single daily dose sufficed to keep the temperature at a lower level. But in grave cases it usually went back to the previous heights. In many instances the mental and nervous condition improved; there was less subsultus tendinum and delirium; sleep was promoted, and the general appearance of a fever ward was one of comparative rest and comfort.

With the fall in temperature free perspiration often occurred, and in some cases a chill. Vomiting was noticed in a few instances, but defervescence was not prevented thereby.

Six patients, within one hour after taking twenty or thirty grains of antipyrine, presented symptoms of collapse. In three the temperature became subnormal. In all there was profuse perspiration lasting several hours. In one the radial pulse disappeared, there was cyanosis, with dyspnea and cold extremities. Heaters and subcutaneous injections of brandy were required. All rallied, but three died at subsequent periods. The patients who presented these unfavorable symptoms after antipyrine were all much debilitated by prolonged fever. They had high temperatures and were in critical conditions. Under similar circumstances collapse often followed a cold bath or any other mode of producing defervescence. The indications were, however, to be extremely cautious in the use of this drug late in the fever when the pulse was above 120, or the first heart sound was deficient in volume.

Several cases were reported, with charts to illustrate the points mentioned above. The most striking instance of collapse is appended.

CASE XIII. Mary F., seventeen years old, entered on the tenth day of the fever. At the beginning of the third week the temperature remained at about  $104^{\circ}$  throughout the twenty-four hours. She became deaf, and had subsultus and carphologia. From the 14th to the 30th day, remissions of several hours were obtained by one or two daily doses of thirty grains of antipyrine, with relief to the nervous symptoms. She took milk and brandy well, and was rational. On the 27th day, however, the antipyretic dose caused marked depression, the temperature falling in one hour five and one-half degrees, to the normal point, and remaining there twelve hours, the pulse being 135 and the skin pale, with extreme perspiration. Brandy was increased to one ounce every hour, and she took that amount or more until her death, two weeks later.

On the 30th day, with temperature  $105^{\circ}$ , pulse 150, and an accession of cerebral and nervous symptoms, a smaller dose of antipyrine, twenty grains, was given. This produced such complete collapse that the patient might have died but for the timely administration of brandy and ether under the skin and the application of heaters to the body. The pulse at the wrist disappeared, there was cyanosis with dyspnea, and extreme sweating. The patient rallied in a few hours, although the temperature at midnight fell to  $96^{\circ}$  and remained subnormal eighteen hours. The following day it gradually rose to  $104^{\circ}$ , but did not reach its previous height. Four days later the fever had abated, although the pulse remained at 150. The patient seemed to be on the road to convalescence, when an attack of phlebitis carried her off on the 41st day.

The reader stated that the drug was probably uniform in quality, as it all came from one laboratory in Germany.

The President said that he hoped that the use of antipyrine would be especially considered this evening, and he called on Dr. Edes to open the discussion.

Dr. R. T. EDES said that he had had no experience in the use of this drug. That there is a certain benefit to be got from antipyretic treatment is not to be doubted, although it is not adapted to all cases, and the pulse and other indications are to be considered as well as the temperature. The latest researches show that fever is due to the retention of heat, rather than to its over production, which would, perhaps, lead us to abstract it, rather than to hinder its formation. There is a serious objection to the use of baths, unless in the form of sponging. The sweating of antipyrine seems to show that it acts by taking heat from the surface, in this respect giving us a substitute for baths, but the speaker thought that the matter had not yet been minutely studied. If it shall be proved that this is the action of the drug, it does not follow of necessity that it is of advantage to use it. It may do harm in other ways; for instance, tartar emetic would have this same effect, but is contraindicated by the depression caused by it. Quinine, in the large doses sometimes used, depresses the heart, while it does not do so in small repeated doses. In Dr. Mason's large number of cases, there were, however, but six cases of collapse, and these all occurred in the late stage of fever.

Dr. G. H. LYMAN said that he had used antipyrine in the same class of cases as those in which it had been employed by Dr. Mason. It is only fair to point out that one of the fatal cases recovered from collapse and died; not from the effect of the drug, but from phlebitis.

Charts are always a little fallacious, and a series of cases otherwise treated, might be brought together, showing the same curves. One of his patients had a rapid fall of temperature after taking antipyrine, but it rose again in a day or two, and then fell without especial treatment. Still, the whole weight of testimony is that antipyrine is a heat-reducing agent. A large hospital gives opportunity for seeing this on a large scale.

Dujardin-Beaumetz has recently used this drug in a different way, giving a moderate dose to bring down the temperature moderately, and then keeping it down with repeated small doses. Dr. Lyman is of opinion that cases without marked cerebral symptoms do as well with quinine, and in this way we avoid collapse. It is a question how much benefit is got from reducing the temperature below that which is normal to the disease.

The pulse is of more value than the temperature in judging of the case, and with increasing experience, the speaker is more and more convinced that unless the temperature is exceedingly high, stimulants are of more service than antipyretics. We must not forget that we are dealing with a disease marked by great depression, and he believes that we have not much improved on the treatment of Stokes, who, thirty-five years ago, anticipated depression by the early use of stimulants, and pushed them if need be. With a low and feeble pulse and a high temperature, quinine serves a good purpose and is not dangerous. The speaker closed by saying that he spoke upon the subject with diffidence, because Dr. Mason had had a large experience with antipyrine which he had not.

Dr. A. M. SEMMER has used antipyrine extensively. Last year he gave thirty grains, and repeated in an hour, according to circumstances. This year he has, with few exceptions, given doses of twenty or fifteen grains. He thinks that there is a certain advantage in its use. In many cases, the temperature takes more than twenty-four hours to rise to its limit, and the patient has that much rest from heat and nervousness. He has seldom seen collapse. The disadvantages are nausea and vomiting, which sometimes come almost instantly, the vomiting lasting some time. In these cases, the temperature is not affected. In a few cases good results were had, and nausea avoided by giving the drug in an enema. The speaker thinks that the smaller doses have as good an effect on the disease as large ones, but they do not reduce the temperature so low. He has seldom given seventy grains, as has been done elsewhere. His mild cases that have needed no antipyretic have been treated with milk and one grain doses of quinine as a placebo.

Dr. HENRY I. BOWDITCH thought the communication important. The tact of collapse at times happening after the use of antipyrine, should lead to care in its administration in some cases and in large doses. The use of *heroin* doses seems to be becoming again fashionable, as it was fifty years since, when from some ill effects the "expectant" plan was followed with little or no medicine.

Dr. JAMES AYER said that he believes in the great value of stimulants used to anticipate depression, and especially he believes in the value of carbonate of ammonium. Dr. Ayer inquired as to the analysis of antipyrine.

Dr. FRANCIS H. WILLIAMS said that antipyrine is an alkalioid which is synthetically prepared. It has

been a good deal used in pneumonia, typhoid fever, and erysipelas: it is important not to employ the drug in cases where the heart is weak, as there is danger of its causing collapse. It has been used as a substitute for the salicylates in acute articular rheumatism with success, and is also valuable in the sweating of phthisis. In children, even for those at the breast, it has been used as an antipyretic.

Its action in reducing temperature, although not well understood, is probably not alone through its diaphoretic effects, for the amount of nitrogenous material excreted is diminished by it. When atropine is previously given and diaphoresis is thus prevented, the temperature is still reduced by it.

There are other recent antipyretics, and we may fairly hope that an even more valuable one than antipyrine will be found.

Dr. JOHN G. BLAKE said that the typhoid that he has seen at the City Hospital this year has been of a mild type, and he seldom now sees the severe cases that were common in his student days. He has used dilute hydrochloric acid for twenty years, and finds that it ensures digestion, but no drug cuts short the disease. Mild cases recover as always, and severe ones die of hæmorrhage, ulceration, and so forth. Still there is no doubt but that antipyrine brings down the temperature, and he has seen a remarkable absence of severe symptoms among the forty cases that he has treated this year. As was well expressed by his House Officer, antipyrine takes the place of a bath and makes the patient comfortable. He is glad to learn that its effect is so constant.

Dr. H. C. HAVEN said that the physical properties of antipyrine, that is, its ready solubility and comparative tastelessness, especially adapted it for use in children, the ordinary antipyretic drugs being bulky and difficult to administer in a palatable form. Antipyrine has been quite extensively used in the febrile diseases of childhood in Germany, and to a less extent, in Russia, France, and England. In the *Jahrbuch für Kinderheilkunde*, W. Jacobowitsch has collated all published records of its use in children, some thirty in number. The testimony of these observers is unanimous as to its antipyretic action, and as to its action being relatively greater in children than adults. In several instances, quite large doses, however, were not accompanied by a fall of the temperature, although a considerable degree of collapse seemed to follow its use. Gotze reports two such cases followed by death. The observations of Jacobowitsch seem to have been the most careful of any thus far recorded in children. The action of the drug was studied on both sick and well children. They were weighed the day before and after the administration, and a certain weighed quantity of food given. The temperature was taken in the rectum every two hours. The quantity of the urine and its composition were determined the day before, the day of, and for the forty-eight hours after the use of the drug: an average dose of three to four grammes, or forty-five to sixty grains was not followed by any disagreeable symptoms. In two healthy children, the electro-muscular irritability was tested before and during its use.

Jacobowitsch summarizes his conclusions as follows:

(1) Antipyrine reduces the temperature in healthy, as well as in sick children, but not so much.

(2) The amount of the reduction does not always depend on the size of the dose.

(3) In children, an individual idiosyncrasy is met with. Very large doses sometimes do not reduce the temperature, but do induce collapse.

(4) With the largest doses, the temperature always begins to rise after twenty hours.

(5) The greatest depression is noticed about midnight.

(6) Small children usually bear large doses well. He seldom observed among this class vomiting, never collapse or eruption, and often no sweating.

(7) The electro-muscular irritability rises under its use.

(8) In the majority of cases, the daily amount of urine is diminished one-half or more, and its specific gravity increased. The daily amount of urea, uric acid, chloride of sodium, the phosphates and sulphates, is diminished. Forty-eight hours after the last dose, the daily quantity of all urinary constituents exceeds that of the day before its use. Antipyrine cannot be recognized in the urine after forty-eight hours from the last dose.

He does not attempt to give a positive answer as to the propriety of its use in febrile conditions in childhood, but thinks it probable that it arrests oxidation, and hence is not fitted for long continued administrations.

Dr. Haven mentioned the case of an infant under his care, suffering from right apex pneumonia, to whom was given by mistake of the mother, ten grains of antipyrine for four doses certainly, and probably more, at intervals of one-half an hour. No vomiting occurred till after the fifth dose. The temperature, which was nearly 104°, was not reduced. There were neither collapse, eruption, nor sweating. There was, however, complete suppression of urine for over twenty-four hours.

Dr. GEORGE B. SHATTUCK said that, to the best of his belief, antipyrine was first used in this country at the Boston City Hospital. It had now been in use there about eighteen months, a long enough time to enable us to arrive at definite conclusions in regard to its value. In answer to Dr. Bowditch's expression of a desire for formulated conclusions as to its effects, he referred to a paper read by him before the Clinical Section of the Suffolk District Medical Society last May, and published in the *MEDICAL AND SURGICAL JOURNAL*, July 23d, in which the results with antipyrine up to that time were given. Dr. Shattuck had seen no occasion to alter the opinions then expressed. A judicious administration gave sleep to the wakeful and made the restless tranquil. This was a great gain, even though the reduced temperature subsequently rose again. Antipyrine did not otherwise alter the course of a disease and certainly had no specific action in typhoid fever. He was convinced that, as might be expected from its composition, it had in common with quinine some distinct antipyretic action other than that resulting from mere diaphoresis and evaporation. His experience certainly led him to regard it as a more constant, prompt, efficient and less disturbing antipyretic than quinine.

Antipyrine had been tried in a great variety of doses at the Hospital, and Du Jardin-Bennet's suggestion of continued small doses—say of five grains—(to prolong the lowered temperature, had been anticipated at the Hospital, but without marked success. There undoubtedly were individuals who exhibited idiosyncrasies toward this as toward other drugs; with such the dose should, of course, be regulated or its use given up. Dr. Shattuck did not believe that the rate of mortality

had been much affected one way or the other in typhoid since the introduction of antipyrine at the Hospital, but did think that the comfort of the patients had been promoted. He considered it a prompt, safe, efficient, and convenient antipyretic.

DR. S. L. ARBOR said that after so full a discussion of the whole subject little remained to be said. The Society was under great obligations to Dr. Mason for his paper, which he understood as being a presentation of the facts of his experience in the use of antipyrine, rather than argument in its favor. For his part, he felt that the end sought for in employing it could be attained quite as effectually and more safely by the external application of cold by sponge baths, ice water being used, if necessary. This method was more manageable, as the process could be stopped at once as the temperature fell, without the danger involved in using antipyrine, the action of which could not be limited after it was administered.

DR. MORTON H. PRINCE said that he was investigating the etiology of cases throughout the city and was able to confirm the reader's opinion, that some of the milder cases were not reported to the Board of Health. Of course, such an investigation is a more complicated affair in the city than in the country, and his work so far is merely preliminary; but he has tabulated seventy-five cases to-day, and finds that ten of them were surely imported, while in twenty-three cases importation was more or less probable, and in six no conclusion could be reached. Of the seventy-five cases, twenty presented evidence of contagion, probably because disinfectants are, in a large proportion of cases, not used. No case could be attributed to the use of milk. The speaker has been sceptical as to sewer gas being a cause; but has met with a group of cases in which, if the disease were imported, it must have been latent for one month and six days in the first case, and more in the second; while the first person to be taken sick had been hardly out of the house for that time since moving in, and the second patient, the husband of the first, becoming sick four days later, probably did not contract the disease from his wife. Two other cases followed. Examination showed a connection between the drain and furnace pipes.

DR. MASON said, in closing the discussion, that he had not intended to convey the impression that antipyrine was a dangerous drug, but that in critical cases it must be used with caution, like all other agents which reduce fever quickly. We should infer from the remarks of some of the speakers that they thought it best not to interfere with these prolonged high temperatures. Would the same conservatism extend to cases of sunstroke, in which it was generally thought desirable to resort to prompt refrigeration?

If extreme bodily heat, or prolonged heat of a lower degree, is a source of danger, then antipyretic drugs must be regarded as important additions to therapeutics. Of this class the one under discussion was the most valuable thus far discovered.

DR. S. L. ARBOR said as to the question of the cause of typhoid in the city, he had been very much impressed of late years with the fact that nearly all the cases of this disease in his private practice were in persons in easy circumstances who had passed the summer in the country and had returned to the city in the autumn feeling "poorly," with loss of appetite and strength, which developed into typhoid; or patients who came back to the city from a house in the country where

there were cases of this disease; or thirdly, cases originating in the city where there was what seemed to be a sufficient local cause in broken drains, worn-out soil pipes, or untrapped sinks or basins. In repeated instances, these defects had been long known to exist by the persons exposed to their influence, but had not been corrected, owing to the parsimony or negligence of landlords, or the inefficiency or carelessness of Board of Health inspectors.

## ANNUAL MEETING OF THE NEW YORK STATE MEDICAL ASSOCIATION.<sup>1</sup>

SECOND DAY.—MORNING SESSION.

The President in the Chair.

A communication from the American Medical Association regarding certain State legislation was referred to a committee of three, to report to-morrow.

After certain other business had been transacted, the Society again took up the

### DISCUSSION ON PNEUMONIA.

DR. CHARLES C. STOCKTON discussed the seventh question propounded by Dr. Flint in a brief paper, and said he thought the special manner in which the temperature should be lowered would depend upon the individual case; a single antipyretic would not answer in all cases of elevation of the temperature. He had sometimes used quinine and antipyrine successfully in the same case. Regarding antipyrine, he recommended its use in from fifteen to twenty-grain doses, repeated once in eight to twelve hours. When so used, it had never produced any toxic effects upon the heart, and it had the desired effect upon the temperature.

DR. E. D. FERGUSON'S experience with antipyrine had been similar.

DR. J. G. ORTOLAN discussed the eighth question in a brief paper. He had never seen an unqualified case of relapse of acute lobar pneumonia during or shortly after the period of convalescence, but one attack seemed to predispose to subsequent ones in the same lobule. He thought that pneumonia was a non-infectious essential fever. He also spoke of complications and diseases to which pneumonia predisposed.

DR. F. HYDE had found evidence at autopsies in several cases of acute lobar pneumonia, that there had been early and persistent thrombosis, as well as embolism of the veins, and in two cases, there was embolism in the arteries as well. This condition he thought occurred more frequently than was supposed, and he could see why remedial measures proved of no avail, and why death occurred so early in the course of the disease.

### MEDICO-LEGAL BEARING OF PELVIC INJURIES IN WOMEN.

DR. ELY VAN DE WARKER, of Syracuse, read a paper with this title, in which he said that actions at law to recover damages for injuries sustained to the pelvic organs in women, were becoming quite frequent and involved large sums of money. They were usually brought against corporations, particularly cities and villages, and railroad companies. He cited three illustrative cases, by which it appeared that the facts of the case, could they be obtained by a thorough medical examination, were in favor of the defendant, but the ver-

<sup>1</sup> Concluded from page 534.

diet was likely to be in favor of the complainant. Some of the women attributed conscientiously, but erroneously, their symptoms to the injury sustained, but most of the cases were of a fraudulent nature. In all, perhaps, there would be found a history of previous pelvic inflammation, or affections which would fully account for the symptoms present. The impossibility of a fall of some nature, which was the usual accident in these cases, producing such commotion of the healthy uterus and pelvic organs as to cause permanent displacement of the womb, or swelling or pelvic inflammation and abscess was evident to the physician, but not to the simple jurymen, whose sympathies were appealed to by a suffering woman standing before him, while the other party to the action was a heartless corporation with a supposed unlimited supply of money.

DR. WILLIAMS, of Boston, and DR. ALONZO CLARK, of New York, were at this point introduced to the Association.

#### ADDRESS ON SOME OF THE RELATIONS OF PHYSIOLOGY TO THE PRACTICE OF MEDICINE.

DR. AUSTIN FLINT, JR., read the address, and said that physiology was the only rational basis of scientific medicine. This was true even should we use the term medicine in its widest signification, including in it the practice of surgery, gynecology, and pathology. A knowledge of anatomy and physiology was a most important requisite in making a correct diagnosis.

The necessity for a knowledge of physiology was evident in the study of valvular lesions of the heart, for our ability to diagnose heart lesions depended upon our familiarity with the functions of the heart and the sounds produced by their blood current in health. Dr. Flint analyzed the heart sounds in different diseased conditions of the heart, in proof of his assertion that a knowledge of physiology was an important element in scientific medicine. In the same line, he cited certain affections of the digestive tract, Beaumont's observations upon digestion within the stomach through a gastric fistula, the discovery of vaccination by Jenner, of the circulation of the blood by Harvey, of the manner of bacteria culture by Koch, etc. Regarding bacteria as a causation of disease, it offered wide possibilities, and it was not improbable that methods of prevention and treatment of disease would now be discovered which would be of the greatest benefit to the human race. Methods of bacteria culture might also prove of value in the study of the physiology of the fluids and functions of the body. Dr. Flint referred to an article on the subject of how to treat a fever as based on physiology, which he published in the *American Journal of the Medical Sciences* in 1879, and said that fever meant the rapid use of the heat-producing elements in the economy, and hence the importance of digestion of heat-producing foods during a fever to prevent the burning up of the system. Alcohol in fever was well borne, and temporarily was capable of taking the place of the elements consumed by hyperpyrexia. In phthisis with fever, hydrocarbons should be given, as starch, sugar, cod liver oil; alcohol was well borne by such patients.

#### SECOND DAY.—AFTERNOON SESSION.

DR. E. D. FERGUSON was elected Chairman pro tem. ANTIPEPRINE: ITS POWER TO DIMINISH AND, OCCASIONALLY, ENTIRELY REMOVE LIVER.

By DR. N. S. FILLER was read by title.

#### THE SIGNIFICANCE OF NON-TRAUMATIC INTRA-OCULAR HEMORRHAGE IN DISEASES OF THE HEART, BLOODVESSELS, AND KIDNEYS.

The author, DR. CHARLES STRADMAN BULL, was prevented from being present by sickness in the family.

#### RECTO-LABIAL OR VULVULAR FISTULÆ: THEIR CAUSES AND TREATMENT.

DR. ISAAC E. TAYLOR read the paper, in which he spoke of the comparative rarity of the condition. It was very liable to begin with a vulvar abscess, depending upon an inflammation of the vulvar glands, perhaps excited by injury during coition, masturbation, labor, direct injury, or in cold. A small tumor might exist in the labia prior to breaking down into an abscess, perhaps quite movable, and leading to the suspicion of an ovary in Broca's canal. The history of such a case seen by the author was given. The tumor constituting the suspected ovary broke, and gases and feces escaped by the small opening. Huguier's plates were shown in illustration of the subject matter of the paper. The pathognomonic symptom of vulvular fistule was the escape of air and thin feces. The vulvar opening was usually small, perhaps so small that it would be found with great difficulty. As to the treatment, he adopted the ligature, being in general the method employed by Barton between 1835 and 1840.

The method was simple and efficient, and in view of the great and serious difficulties liable to attend the use of the knife, he thought it deserved much more general employment. The elastic ligature was to be preferred.

After reading the paper, Dr. Taylor presented to the Society a form of obstetric extractors donated to the Association's museum by Dr. Samuel W. Francis of Newport. Dr. Taylor also presented a fetal skull, which showed the effects of moulding during extraction from an equally contracted pelvis. The gifts were accepted with thanks.

DR. EDWARD M. MOORE then read a paper on

#### RECURRING LUXATIONS.

That luxations were likely to recur he would not attempt to prove, for it was a well-known fact. Recurrence of the luxation took place often as a result of violence, but of the action of different forces not connected with violence. Some replacements were maintained with great difficulty. Attention was then called to the tendency of recurrence of luxation in different joints and to the manner of preventing this accident. To prevent recurrence of luxation in the clavicle, the elbow was thrown backward and retained in that position by binding the hand to the side by means of adhesive plaster, or, what was better, by means of his figure 8 bandage, thus the scapula would be carried nearer the vertebral column.

Several interesting cases in which recurrence of luxation took place in the shoulder joint were related and the manner in which the accident was liable to occur was pointed out. His views with regard to luxation occurring in this joint were made clear by certain experiments which he had performed after removal of the flesh about the shoulder and bringing forces applied upon the arm and forearm to bear upon the ligamentous structures. His experiments illustrated incidentally how it was that in many cases of sprains or supposed injury to ligamentous filaments, the symptoms were as serious and more prolonged than in

fractures of bone, for, as was shown in these instances, the ligament gave way only by taking with it a portion of the bone to which it was attached. In luxations of the shoulder, either upon the dorsum of the scapula or into the axilla, examples could be met with in which maintenance of reduction would be found difficult. The manner in which the luxation took place was by gravity, allowing the arm to fall, especially if at the same time the arm was turned more or less forcibly outward. Touching upon recurrence of luxation at the hip joint, the author cited an interesting case which had come under his observation, and had been reported with two others by Bigelow, in which a soldier acquired the tact of dislocating and replacing the head of the femur by a certain twisting motion of the body.

#### THE DIFFERENCE IN THE SYMPTOMS OF STRANGULATED OBLIQUE INGUINAL HERNIA.

DR. FREDERICK HYDE read a paper with this title, in which the following were some of the principal points developed: 1. In proportion to the length of time an inguinal hernia existed would the symptoms and signs of strangulation be mild and chronic. 2. In a case of long standing inguinal hernia in which signs of stricture of the bowels were obscure, there not being evidence of total obstruction to the canal, often it was not safe to wait for fecal regurgitation before deciding that strangulation existed. 3. When strangulation occurred at the first protrusion, the symptoms of strangulation would be found to be more marked. 4. If hiccough and fecal vomiting existed from nearly the beginning of the symptoms, no time was to be lost, herniotomy should be performed at once. 5. If a swelling existed with symptoms of obstruction of the bowel, the patient complaining of severe pain in the abdomen, but of none in the tumor, and had hiccough, although there was absence of marked general disturbance, a fair trial of taxis should be made, and that failing to reduce the tumor, herniotomy should not be delayed. This remark was based on an interesting case, the history of which Dr. Hyde gave in detail. No fecal vomiting occurred, no pain in the tumor even after taxis, but there was some pain in the abdomen, and hiccough. Because of the mildness of the symptoms, the consulting physicians delayed the operation more than twelve days, and when it was finally performed, the strangulation was found to have existed within the abdomen. The patient died. 6. If no strangulated portion were found within the external sac, the finger should be passed internally and adhesions sought for in the neighborhood of the opening. 7. Too long a trial of taxis before dividing a stricture, should be guarded against, as it prepared the way for the death of the patient after herniotomy. 8. After stercoraceous vomiting had set in, taxis should not be applied, but herniotomy should be performed at once, although the prognosis was unfavorable. 9. If after opening the sac, the omentum was found smooth and no intestine could be detected, the omentum should be opened to learn whether it may not contain a strangulated portion of intestine. It was unfair to speak of herniotomy as a dangerous surgical operation *per se*. The danger attending the operation was due to the condition of the sac and its contents and to taxis and delay in operating.

DR. J. W. S. GORLEY read some notes on the subject of Dr. Hyde's paper, in which he reached the

following conclusions: 1. When doubt arises in the mind of the surgeon respecting the existence of strangulation of the intestine or omentum in case of incarcerated hernia, it is his duty to give the patient the benefit of the doubt by at once resorting to the operation of herniotomy. 2. Delay in relieving the strangulation is often fatal, while herniotomy in a case in which no strangulation exists is not usually harmful. 3. Medicinal treatment is often delusive, and local applications, such as opium, tobacco poultices, ice, etc., are in most cases worse than useless. 4. Persistent taxis is infinitely more dangerous than herniotomy, and such taxis, even when it is followed by reduction of the hernial protrusion is often the cause of fatal peritonitis. 5. Another, though rare, effect of violent taxis is the reduction *en masse* of the hernia in its state of strangulation, and the result is but too well known. 6. As a general rule, two minutes of gentle taxis, the patient being in a hot bath, will settle the question as to the possibility of safely reducing the hernia. 7. Therefore, it may be said with propriety that the less taxis, the less ice, the less other topical applications, the less opium, the less general or special meddling interference which often do serious injury to the intestine, the better the chances of recovery in the event of herniotomy. This is particularly the case in femoral hernia.

I have abstained from incising the neck of the sac in femoral hernia, but have made division by simply insinuating the index finger through the free opening made in the sac until it enters the abdominal cavity, and have had no trouble in effecting reduction of the intestine, the object of the procedure being to avoid division of the obturator artery should it be abnormally situated. I coincide with Dr. Hyde that herniotomy is not *per se* a dangerous operation. Dr. Gouley said further that if it seemed necessary in a case of inguinal hernia after herniotomy, he would open the abdominal cavity in order to relieve the strangulated intestine.

#### MEDICINAL AND DIETETIC THERAPEUTICS OF THE COMMON FORMS OF CHRONIC INTESTINAL CATARRH.

DR. JOHN S. JAMISON read the paper which was supplementary to one read last year. It called out considerable discussion.

#### SECOND DAY.—NIGHT SESSION.

The society was called to order by DR. JOSEPH C. GREENE, vice-president from the Fourth District.

#### A CURSORY REVIEW OF THE EPIDEMIC AND ENDEMIC DISEASES OF SULLIVAN COUNTY DURING THE LAST THIRTY-FOUR YEARS.

DR. ISAAC PURDY read the paper. The first years of the period, commencing in 1850, pneumonia and fevers of a sthenic type prevailed, in which it was common to bleed, to employ cathartics, diuretics, and a depleting system of treatment, and this course seemed to be indicated as being followed by the best results. About the beginning of 1854, typhoid fever was heard from in the distance, and soon reached Sullivan County, and for several years pneumonia and other forms of disease took on a typhoid character, and this period was marked by the fact that in nearly all cases the asthenic form of disease showed itself; a depleting course of treatment was followed by the worst results. Close attention had to be given to the diet, encouraging nutrition, and to checking excessive discharges. About 1860, diphtheria began to prevail in

Delaware and marched up the Delaware River, and existed in Sullivan County in the epidemic form for about five years, being very violent, and carrying away many patients. The odor of persons suffering from the disease was peculiar, and could be recognized at a great distance from the sick-bed. In the author's opinion it was a constitutional, not a local affection, although the local deposit, constituting diphtheritic croup, was present. About 1862-63, it was present in the form of black fever, petechial fever, etc., being in places very malignant. Afterward it again appeared as genuine diphtheria of the throat. In these cases turpentine and sweet oil were applied to the throat at night with benefit. During a part of this period dysentery prevailed, first severe, then of mild type. Scarlet fever was present at intervals of about five years, sometimes of severe, sometimes of mild character. Rubella or measles had occurred at different periods, but in general required little treatment. Occasionally diphtheritic cases occur up to the present time, but the contagion was generally brought from afar. Typhoid fever continued to prevail more or less, especially in the fall months, typhoid-pneumonia during the winter, up to 1881. The spread of typhoid fever up the Hudson and its tributaries occurred at one period. The highest point was situated twelve hundred feet above the level of the sea, at Montauk. The treatment consisted chiefly in moving the bowels, particularly by calomel, and then quinine as a sheet-anchor.

The discussion which followed was lengthy, of a general nature, particularly with regard to the treatment of diphtheria, and was participated in by Drs. Peters, Kneeland, Colvin, Garrish, Cronyn and Pomeroy.

#### REMOVAL OF AN ENTEROLITH: PRESENTATION OF THE SPECIMEN.

Dr. W. B. SABIN read the paper which had first been read at the Saratoga meeting of the Branch Association.

#### COMMERCIAL PRESCRIPTIONS.

Dr. HENRY VAN ZANDT, the author of the paper, was of opinion that physicians should write their own prescriptions and have their medicines compounded by the druggist or do the compounding themselves, and not depend upon the preparations coming from commercial houses, and regarding the exact nature of which they must necessarily be more or less in doubt.

#### PROPHYLAXIS.

Dr. ISAAC DE ZOCCHE chose this subject for a paper, in which he pointed out the advantages of preventive over curative measures.

The authors of the following papers were not present to read them:—

#### THE RELATION OF DRINK TO INSANITY.

By Dr. G. Alder Blumer.

#### TUMORS OF THE JAW.

By Dr. H. S. Tremaine.

#### THE TREATMENT OF INCONTINENCE OF URINE IN WOMEN RESULTING FROM HYPERPLASIA AND PARALYSIS OF THE UTERUS.

By Nathan Bozeman, M.D.

#### SKIN FLAPS IN AMPUTATIONS.

By Dr. U. C. Lynde; also by the same author,

#### UMBILICAL HEMORRHAGE IN INFANTS.

#### THIRD DAY.—MORNING SESSION.

The President, Dr. GRAY, in the chair.

The number of members registered was a little over two hundred and twenty. The total fellowship for the entire State is about five hundred and fourteen.

The nominating committee had named for president, Dr. E. M. Moore, of Rochester; vice-presidents, according to districts, Dr. William Gillis of the first, Dr. H. Van Zandt, of the second, Dr. Frederick Hyde of the third, Dr. Desautel Guernsey of the fifth; for council, members from different districts, Drs. E. M. Lyon, Ira H. Abell, Thomas Wilson, F. W. Ross, S. T. Clark, E. S. F. Arnold.

The secretary was instructed to cast the ballot of the association, which he did in the affirmative, and the president declared the gentlemen named elected.

Dr. FELL, of Erie County, then read a paper on,

#### SOME ETIOLOGICAL FACTORS IN THE ACNEFORM DISEASES.

Dr. Fell, of Erie County, read a paper in which he described some cases of rebellious acne which had come under his observation and which had finally yielded to treatment, the cure, he believed, bidding fair to be of a permanent nature. This opinion was founded on his views regarding the possible or probable etiology of the disease. It was true his views were new, but as far as his own observation had gone, they were substantiated by facts. In a large number of examinations of the contents of the little acne tumors he had always been enabled to find the demodex folliculorum, usually from six to ten in number, while the presence of this mite in the skin was not of unusual occurrence, and though long known, it had not been regarded as the cause of acneform disease. He had found them in the pus or oil globule, and not in the indurated matter. While their presence in few numbers might not give rise to apparent disease of the skin, he thought that when large numbers existed they might stand in the relation of etiological factors of considerable importance.

The committee of three, appointed by the president to report on the communication from the American Medical Association, recommending that a uniform law be pressed for passage by the various State legislatures, reported that it was inexpedient for the society to enter upon the discussion of the subject at the present time.

#### OXYGEN IN THE TREATMENT OF PNEUMONIA.

Dr. JANEWAY, by request, made some remarks on this subject before proceeding to read his address in pathology. According to his experience, oxygen inhalation in pneumonia was of marked benefit. It was especially serviceable in commencing cyanosis, or just previous to this symptom; its use should not be delayed until cyanosis had become well marked. If employed at the proper time it would often be found to tide life over the critical point and lead the patient on to recovery.

Dr. JANEWAY would also add to the discussion on pneumonia that he had seen one case of pneumonia, in which the patient had a relapse at the end of a week,

it being as much a case of relapse as are cases of relapse of typhoid fever. He said further that he had seen a number of cases in which tuberculosis of the upper lobe of the lung had occurred in patients who had suffered from pneumonia, and he was of opinion that the attack of pneumonia had left the lung in a weakened state, fitting the soil for the development of tubercle bacilli.

Dr. Janeway then proceeded to read his address on pathology, which was devoted largely to the mention of the advances made in pathology, particularly during the past few years, and the relation of pathology to exact diagnosis and aetiology of disease. The importance of culture methods adopted by Koch, the value of the discoveries of Pasteur regarding anthrax and hydrophobia, etc., received attention. The field for labor and new discoveries was still great, and offered excellent opportunities for able and progressive young men. The backwardness of this country in new scientific discovery was attributed in large part to want of government aid, such as was given in Germany and other countries of Europe. Special paths for investigation were offered in tetanus, anemia, malignant tumors, lithemia, etc. Dr. Janeway thought vaccination should be done, if possible, before the third day after exposure to small-pox, if it were desired to abort the attack; otherwise, it might be too late.

The Library Committee made its report, by which it appeared that a room had been secured in the Carnegie Laboratory. The entire number of volumes was about 3,450, and more than 1,000 pamphlets had been received. Some interesting specimens had been presented which it was hoped would form the nucleus of a museum in connection with the library.

#### THIRD DAY.—AFTERNOON SESSION.

DARWIN COLVIN, M.D., Vice-President, in the Chair.

A CASE OF POISONING BY TWO GRAINS OF STRYCHNIA: TREATMENT, CHLORAL HYDRATE AND COFFEE.

By WILLIAM FITCH, M.D. Read by title.

A CASE OF GALL STONES, PATENT AND CONCEALED: EXPLORATORY LAPAROTOMY, WITH AUTOPSY EIGHT WEEKS LATER.

Dr. W. W. SEYMOUR gave the history of a case of gall stone, in which the usual symptoms were present, but the gall bladder could not be felt through the abdominal walls. Nevertheless, the patient's sufferings were such and her health so reduced, that an incision was made for the purpose of removing the supposed stone or stones. The gall bladder was found empty; there was a hard nodule involving the cystic and hepatic ducts, and believing that the patient's symptoms were due to malignant disease, the abdominal wound was closed. Eight weeks later the patient died, markedly emaciated and jaundiced. In the upper margin of the right lobe of the liver, was the cancerous patch; the gall bladder was empty; the common duct impervious; the junction of the cystic and hepatic ducts were involved in the hard mass, which was of the size of a hen's egg, and continuous with the right lobe of the liver. The hepatic duct was enormously dilated, and filled with gall stones the size of a peach nut; an ulcerative opening led from the upper part of the hepatic duct into an abscess cavity, an inch and a half in diameter, in the right lobe of the liver, where a gall stone was found. The hard mass was cancer.

Dr. NELSON L. NORTH then read a paper on

THE THERAPY OF THE CHLORIDES: ANTISEPTIC A PROMINENT AND IMPORTANT FACTOR IN THEIR MEDICINAL ACTION.

The following papers were read by title:

THE TREATMENT OF ABSCESS.

By Dr. J. D. RUSHMORE.

CHRONIC CATARRHAL GASTRITIS: FATAL FROM COMPLICATION OF SUDDEN ENLARGEMENT OF THE THYROID GLAND.

By Dr. William H. Thayer.

THE PROPER DISPOSITION OF STREET SWEEPINGS, ASHES, SWILL, AND GARBAGE IN OUR CITIES.

By Dr. Albert H. Briggs.

ERGOT: ITS USES AND MISUSES.

By Dr. J. K. LEANING.

NUTRITION IN LITHEMIA.

By Dr. Charles G. Stockton.

Dr. ROBERT NEWMAN then read a paper on

CAUSES OF FAILURE IN THE TREATMENT OF URETHRAL STRICTURE BY ELECTROLYSIS.

The author said this method of treatment had been so successful in his own hands that he was not aware of any failures until his attention had been drawn to a paper on the subject quite recently. He then made some inquiries and found that failures did sometimes occur in the hands of those of little experience with the method. The cause of failures could be given in two words—bad management. This could be classed under three heads— incompetence on the part of the operator; error in diagnosis, and faulty instruments. These headings were treated of at considerable length, the points being sustained by reference to letters, cases, and instruments.

Dr. G. C. H. MEIER corroborated the statements of the author from his own experience, and testified to the excellent results obtained by this harmless method of treatment when properly carried out. It was true that it was not until he had assisted Dr. Newman in his public and private practice for some time that he was enabled alone to give the patient the full benefit of the treatment of urethral stricture by electrolysis. The paper was also discussed by Dr. Manley.

Dr. W. W. SEYMOUR read a paper which he had read at the Branch meeting at Saratoga, on

PELVIC HEMATOCELE: ITS DIAGNOSIS AND TREATMENT.

A great many cases had occurred in his own and in his father's practice, going to show that pelvic hæmatocele was of much more frequent occurrence than was stated by most authorities. Speaking of treatment, he said that where there was a tendency to increase or to interfere with the function of neighboring organs, aspiration might give prompt relief. Aspiration failing, and suppurative taking place, he was disposed to make incision per vaginam and irrigate.

A short session was held at night at the Carnegie Laboratory, where Dr. Frederick S. Dennis read a paper on

THE ACTION OF MICRO-ORGANISMS UPON SURGICAL WOUNDS.—WITH DEMONSTRATIONS.

The author drew a diagram, classifying bacteria, and

pictured an operating room to be disinfected before use by throwing into it hot steam. The Society adjourned to partake of a banquet at the Murray Hill Hotel.

#### FOURTH DAY.—MORNING SESSION.

Dr. William Gillis in the Chair.

Dr. SAMUEL W. SMITH read a paper entitled

#### THE HISTORY AND TREATMENT OF THIRTY CASES OF DIPHTHERIA.

The great mortality from diphtheria was shown by figures obtained at the Board of Health for this city, from which it appeared that out of an average of about 2,500 cases yearly for several years past, there had been a mortality of nearly fifty per cent., the rate of mortality varying slightly from year to year. In order to test the value of a given method of treatment, Dr. Smith employed that adopted by Dr. Billington, described in a paper read before a Section of the New York Academy of Medicine. It consisted in syringing the nose and pharynx every two hours with a solution of chloride of sodium, a teaspoonful to a pint of warm water, and to which Dr. Smith added a teaspoonful of borax. The syringing should be done in a very thorough manner. In addition, the throat was sprayed with a solution of lime water and carbolic acid, and tincture of chloride of iron and glycerine administered, alternated with chlorate of potash. Of the thirty cases, there were five deaths.

#### REMARKS ON PERI-UTERINE HEMATOMA.

Dr. George T. Harrison read the paper, gave the history of a case, and treated of peri-uterine hematoma in a general way, taking up the questions of diagnosis, treatment, etc.

#### A CASE OF CANCER OF THE KIDNEYS.—REMARKS.

Dr. JOHN SHREADY read a paper in which he described a case of cancer of the kidney occurring in a child, and which had been reported in the proceedings of the New York Pathological Society. The differential diagnosis was considered. In the child, the diagnosis was comparatively easy to make, but the rarity of the affection might cause the physician to overlook the true nature of the case.

The following papers were read by title:

#### THE MODERN ASPECT OF THERAPEUTICS.

By Dr. T. H. Mauley.

#### THE ALGAS IN CROSS-BREEDING; ALSO, PESSARIES AND THEIR USES.

By Dr. Jacob Hartmann.

#### NOTES ON CONTRACTURE OF THE BLADDER CONSEQUENT UPON CYSTITIS.

By Dr. J. W. S. Conley.

#### FOURTH DAY.—AFTERNOON SESSION.

#### ON THE TREATMENT OF SPONDYLITIS OR CARIES OF THE SPINE BY PARTIAL SUSPENSION AND THE PLASTER-OF-PARIS JACKET, AND THE TREATMENT OF ROYAL LATERAL CURVATURE BY GYMNASTICS AND PARTIAL SUSPENSION AND THE PLASTER-OF-PARIS CAST. DEMONSTRATIONS BY PRACTICAL APPLICATION TO CASES.

R. Lewis A. Sayre, M.D.

The Society then adjourned, to meet in New York on the third Tuesday in November, 1886.

## Recent Literature.

*An Introduction to the Study of the Diseases of the Nervous System; being Lectures Delivered in the University of Edinburgh during the Tercentenary Year.* By THOMAS GRAINGER STEWART, M.D. Philadelphia: J. B. Lippincott Co. 1885. pp. xvi+237.

These lectures were published at the request of the class to whom they were delivered. The object of the lecturer is to give a connected description of the anatomy and physiology of the nervous system in relation to symptomatology. Attention is also given to methods of examining patients.

The object the author has in view is attained, and he has produced a book which will give valuable assistance to both student and practitioner. In it are found nearly all the facts and data contained in the more bulky volumes of Ross, of course without the clinical descriptions. We can recommend the book as a safe and valuable guide.

The chapters in which the anatomy is considered and those devoted to sensory and motor functions give the facts briefly and intelligently. Occasionally there is a lack of fullness in some sections, as in regard to organic reflexes, especially those of the bladder.

Sometimes the common English name is given in place of one which is quite as common, as perforating ulcers instead of *mal perforant*, the latter name not appearing anywhere even as a synonyme.

The chapters on cerebral and mental functions are too brief and lack in clearness, being in these respects much inferior to the rest of the book. The chapter on treatment is not satisfactory, and might have been omitted without loss. Electricity, massage, Swedish movement-cure cannot be described in three or four pages.

The illustrations add greatly to the value of this book, and renders the descriptions much more intelligible to the student. A better cut showing the cerebral convolutions would have been one following Ecker. The nomenclature of convolutions is erroneous in regard to the angular gyrus, which should be represented as passing around the end of the fissure, named mid. temporo-sphenoidal in Fig. 22.

*The Principles and Practice of Surgery.* By JOHN ASHMEUT, JR., M.D., Professor of Clinical Surgery in the University of Pennsylvania; Senior Surgeon to the Children's Hospital; Consulting Surgeon to the Women's Hospital, etc.; Fourth Edition, enlarged and thoroughly revised. 8vo. pp. 1118. Philadelphia: Lea Bros. & Co., 1885.

With the fourth edition of this excellent work, over fifty new pages appear; a necessary addition to keep pace with the rapid advances in surgical science. To what bulky dimensions will our text-books of the future attain, if their authors are obliged to keep on adding extra pages with every new edition, in spite of their endeavors to keep within reasonable limits. How this difficulty may be met is hard to determine, unless it be by gradually dropping out special subjects, such as of the eye and ear, of which an example has been already set in some of the later editions of the larger text-books.

The author has refrained from giving undue promi-

nence to any one or more subjects to the detriment of others, a tendency difficult to combat in all works of the kind.

Of the illustrations, many are new, the rest are largely and well selected from the works of Erichsen, Bryant, Liston, Druitt, Fergusson and others.

Though the work is necessarily less exhaustive and argumentative than the larger works or monographs, and cannot therefore be of the same service to the practising surgeon, yet it is written with so much conciseness and impartiality, that it is to be highly commended to all those who wish to obtain an unbiased view of modern surgery from an American standpoint.

*Lectures on the Principles of House Drainage*, delivered before the Suffolk District Medical Society. (Section for Clinical Medicine, Pathology, and Hygiene) and the Boston Society of Architects. By J. PICKERING PUTNAM, Architect. Boston: Ticknor & Co., 1886. pp. 125.

The author of these lectures has given careful attention to many of the defects existing in the ordinary forms of fixtures employed in the plumbing of houses both private and public, and as a result of his experience, these lectures were delivered during the past season.

The subjects treated are mainly, traps, fixtures, and soil-pipes, in all of which the author has devised valuable modifications and appliances. The subject of trap-siphonage is fully treated and the necessity of means for its prevention are clearly set forth. The book is illustrated with seventy cuts.

*The Pedigree of Disease. Being Six Lectures on Temperament, Idiocy, and Diathesis*. Delivered in the Theatre of the Royal College of Surgeons in the session of 1881. By Jonathan Hutchinson, F. R. S., Late Professor of Surgery and Pathology in the college, etc. New York: Wm. Wood & Co. 1885.

We have already favorably noticed these lectures in the English edition, and are glad to see that an American publisher has placed them within easy reach of the profession upon this side of the water.

*A Practical Treatise on Diseases of the Kidneys and Urinary Derangements*. By CHARLES HENRY KALKE, M. D., (Cantab.), etc. With illustrations. Philadelphia: P. Blakiston, Son & Co. 1885.

We think the author of this 16mo. volume of 570 pages has accomplished the object, which his preface tells us he aimed at—of presenting the student and practitioner with a clear, concise and systematic account of urinary pathology and therapeutics, based upon the latest ascertained facts, and supported by the best authorities. The student will find in these pages all necessary instruction upon the subjects indicated in the title imparted in a candid and not dogmatic manner, and the practitioner will find a ready and convenient reference book. The author's previous book on the "Morbid Conditions of the Urine dependent upon Derangements of Digestion," published in London in 1882, is now out of print: such portions of it as seemed desirable, have been incorporated in this volume, and it will not be republished.

This American edition, belonging to the "Practical Series" of P. Blakiston, Son & Co., although of a very convenient form, is marked by some unnecessary errors and indistinctness of type.

## Medical and Surgical Journal.

THURSDAY, DECEMBER 3, 1885.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly, by CUPPLES, UPHAM & CO., Boston. Price, 15 cents a number; \$5.00 a year, including postage, to subscribers in the United States and Canada. Foreign subscribers are charged the postage in addition.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale by the undersigned, to whom communications by mail should be sent by money-order, draft, or registered letter.*

CUPPLES, UPHAM & COMPANY,

283 WASHINGTON STREET, BOSTON, MASS.

### THE HEALTH OF WOMEN COLLEGE GRADUATES.

THE question as to whether the so-called "higher education of women" involves an impairment of her physiological equilibrium, which question from its collateral relations with important problems of social science, political economy, not to mention politics, has been debated with considerable activity, has been sought to be answered by the statistical method through the endeavors of some members of the class most directly concerned, namely, the college alumnae themselves. Some three years ago a committee appointed by the association of collegiate alumnae prepared a lengthy schedule embracing about forty questions under various divisions, which include conditions of childhood, individual health, family health, college conditions, post-graduation conditions, and others. These circulars were sent to the graduates of all colleges in the United States open to women, numbering twelve. The graduates from these institutions up to 1882, numbered 1,290. Replies were received from 705 women. The Vassar alumnae furnished nearly half (311) of these returns, as indeed their total numbers were largely in excess of those of any other college. We remark in passing, that eight, or two-thirds of these colleges had at the time of this inquiry been organized less than seventeen years. These replies were placed at the disposal of the Massachusetts Bureau of Statistics of Labor, which by a justifiable extension of its legally established functions, undertook the tabulation of the data, and embodied these results in its Sixteenth Annual Report.

The reports made by these women contain many points of interest to the medical mind, and we may say that the general impressions which they convey of the physical state of these college women coincide with what observation has inclined us to believe, — namely, that the bodily health of these graduates is probably as good on the average as that of non-collegiate women of similar social grades, and that it will compare favorably with that of American women in general. Certainly there seems little reason to suppose that judicious mental work will necessarily prove more in-

jealous than the labors either of the woman of fashionable society on the one hand, or of the shop girl on the other.

With no disposition, then, to depreciate the useful work of these ladies, we venture to suggest some criticisms that might be made upon their methods of investigation. The most obvious of these is in regard to the definiteness of the classification which they make of certain conditions which have not the sharpness of outline that they would give them. We are inclined to regard the discrepant faculty, from its demands upon the observation and the judgment, as one of the highest of the human mind. The accurate classification of any series of objects or facts presupposes not only a thorough knowledge of the subject, but certain common canons of discrimination which if possible should be applied by a single mind. Yet on the important subject of the state of physical health, the classification is made by over 700 observers, who even if thoroughly cognizant of the facts cannot possibly have any fixed standard whereby to govern their decision. Thus 272 report themselves as in excellent health, 277 as in good health, 85 as in indifferent, and 35 as in poor health, while 36 who declined to classify themselves under any of the foregoing categories are "averaged" by the committee under the term "fair." Now, it must be evident to any physician that a state of health which to one person would seem to warrant the term good, might to another appear only indifferent, while a third of more cheerful temperament, a less vivid recollection of discomforts passed or a wider experience with sick people, might speak of her own health as excellent. In spite of periodical headaches one woman might be in "excellent" general health, while because of them her classmate might be in but indifferent health. On such an uncertain foundation as this is based the statement that 3 per cent. more women were in indifferent or poor health on entering college than on leaving it, and hence the deduction that the "college training . . . can be counted as a positive physical benefaction." An even finer mathematical expression is that of a diminution of .29 per cent. in good health from the time of entering college to that of the investigation.

The same criticism can be made upon the information furnished in regard to other points, as for instance, upon whether the amount of study exceeded "the bounds of discretion." Just 11 per cent. outstepped this limit. Yet 28.22 per cent. studied "severely." What is severe study? and just where does it border upon moderate study, or "moderately to severe" study? And how is one who was oblivious at the time to overstepping the bounds of discretion in study to arrive at that consciousness later except through the supposed evil consequences of such transgression? It appears from the tables that among the severe students the classes in good and fair health increased during the college course, while the classes in excellent, indifferent, and poor health, diminished in comparison with their respective numbers before entering college.

The worriers and the non-worriers are also defined with a sharpness of diagnosis which excites envy in

the mind of the physician. 172 women worried over their studies, 89 worried over their personal affairs, and 131 over both, while 313 worried over neither. Whether a certain number of units of worry are allowed, below which one is classed as a non-worrier, or whether, as seems to be implied, this class includes only those who never had a worry (*sgu.*, (Webster) perplexity, trouble, vexation), is not stated with equal definiteness. If the latter is the criterion adopted, it certainly follows, as claimed by the committee, that "the broader culture resulting from a college education carries with it the only specific for this evil."

The causes of such disorders as existed were sought for and in the majority of cases were given. 135 claimed a constitutional tendency to such troubles, 73 traced their weakness to emotional strain, 47 to physical accident, 81 to intellectual overwork, and a like number to bad sanitary conditions. There were, however, some sufferers (141) who did not feel certain of the cause of their trouble.

Though one may fail to be convinced of the absolute reliability of some of the foregoing statistics, there are collected some interesting facts which do admit of more or less definite numerical expression. 411 out of the 705 women were brought up in the country, and only 165 entered college from the cities; about 124 had passed their lives in both city and country. The health figures (computed as above related) seem to show a somewhat better condition of health among the city than among the country girls.

The average first age of study was five and one-half years, while the average age at entering college was 18.35, the latter being a little in excess, we presume, of the age at which most boys enter college.

The facts regarding menstruation are of interest: 198 girls began this function at the age of 13, 192 at 14, 94 at 12, 90 at 15; 1 each is reported at 9 and at 20 years. While in college 239 abstained from physical exercise during the menstrual period, and 2 from mental work only; 73 abstained from both, while 391 do not answer this question. The conditions during menstruation are given for the various periods, developmental, collegiate, and post-collegiate, whereby it appears that only 163 have had no trouble, while the rest have suffered from irregularities, uterine and reflex pain, one or all. We notice that the number who were free from menstrual trouble during college life is nearly 100 less than of those thus exempt during the period of development. A table which would have been of great value in addition to the comparative tables that are published is one showing the relation between the various menstrual disorders and the cessation of physical and mental work during the menstrual periods. Instead of this we have merely one giving the general "health" compared with the interval between the establishment of menstruation and entering college.

The vast majority of the girls, it is noted (92 per cent.) entered society during college life either none at all or very little.

Other subjects mentioned, such as the amount and

kind of daily exercise, and the number and character of the disorders reported are more or less suggestive, but space forbids allusion to them.

We take leave, however, to refer to one additional point of some importance. The average period since graduation of these women has been 6.2 years. Of the 705 women but 196, being 27.8 per cent., are married. We are told with an earnestness which savors a little of the humorous, that this small proportion of marriages is due to the deliberate choice of the alumnae themselves who from the training of their reflective powers are not the victims of sudden impulse, but subject their actions to the test of much cool reflection, being thereby exempt from the considerations of interest and of conventionality which are the usual inducements to marriage. Moreover, that late marriages are becoming an indispensable feature of our modern life, so that it is believed that at the age of 60, one-half of these women will have married.

Now it is doubtless true that late marriages are becoming more necessary, but this is due to those business competitions which delay the ability to earn a support, and which effect chiefly the bread-winners of the household, the male sex. Yet on taking up the report of a class in Harvard College, selected quite at random, we find that in six and two-tenths years after graduation (the same period since these women left college) about 30 per cent. had married. But these were the years in which these men were studying their professions and beginning to earn a livelihood for themselves and their families. Of the same class at the end of their first decennium, 50 per cent. were married. If of these alumnae, even the small proportion of one-half are to be married (they now averaging 28 years of age) in the course of the next 32 years, as is claimed, it is certain that that proportion must be nearly reached in the next seven years.

That the committee do not themselves count with much confidence on the likelihood of late marriages for their associates is shown by their admission that "college women are not as prone to enter upon married life as the majority of women." The old-time slur that men are loth to marry women who may equal if not exceed them in mental power, amounts to little. One of the keenest philosophers of the present day has said, "The truth is that out of the many elements uniting in various proportions to produce in a man's breast that complex emotion which we call love, the strongest are those produced by physical attractions; the next in order of strength are those produced by moral attractions; the weakest are those produced by intellectual attractions; and even these are dependent much less upon acquired knowledge than on natural faculty, quickness, wit, insight. If any think the assertion a derogatory one and inveigh against the masculine character for being thus swayed, we reply that they little know what they say when they thus call in question the divine ordinations."

We confess ourselves to be of the number of those who hold the old-fashioned belief that woman most

happily fills the niche which nature intended her for, in occupying the relations of wife and mother. And while we admit that those whose tastes lead them to the "higher education," may by attention to hygienic principles accomplish their aim without compromising their health, we find ourselves able to quote with approval the words of the committee itself: "If it is shown that their (the colleges') permanent tendency is toward celibacy their influence will not extend beyond the small circle of women who resolve early in life to follow professional pursuits."

#### A NEW HYPNOTIC.

DOCTORS Dujardin-Beaumetz and Bardet have announced to the profession the discovery of a new hypnotic, to which has been given the name of *phényl-méthyl-acétone*, or *acétophénon*. It is a mixed acetone, having for its chemical formula  $C^{11}H^{15}O$ ,  $CH^3$ . The physiological properties have been studied by Popof and Neucki. These experimenters have demonstrated that this product undergoes transformation in the organism into carbonic and benzoic acids, and is finally eliminated in the urine in the state of hippurates.

Dujardin-Beaumetz and Bardet have continued these researches and have signalized very powerful hypnotic properties in this new chemical body. They have proposed to substitute for the cumbersome name of *phényl-méthyl-acétone*, the simpler designation of *hypnone*, a name based on its ascertained physiological properties.

Administered to the adult in doses of from five to fifteen centigrammes mixed with a little glycerine, and given in capsules of gelatine, *phényl-méthyl-acétone* causes a profound sleep, and this hypnotic action is especially marked in cases of insomnia from alcoholism; it has seemed to the French clinicians to be superior as a sleep-producer to chloral and paraldehyde.

This hypnotic was given to nine patients for fifteen days without any symptoms indicating intolerance. The odor of the breath became offensive by reason of the elimination of acetone by the lungs.

When the substance was injected under the skin of young animals (guinea pigs and hares), in the dose of from five to fifteen drops, a marked hypnotic stupor followed, ending in a profound coma, to which the animals succumbed in five or six hours. *Phényl-méthyl-acétone* is a product of the oxidation of ethyl benzine, treated by chromic acid in presence of acetic acid; it is also obtained by the dry distillation of a mixture of acetate and benzoate of lime.

It is a liquid body at the ordinary temperature of 60° to 70° F., crystallizing below this temperature in the form of beautiful white needles. Its odor is very penetrating, resembling both that of bitter almond and orange flowers. It is so intense as to be disagreeable to the patient, and hence the hypnotic is better administered in pill form or in capsules than in any other way.

### SHALL PHYSICIANS REPORT CONTAGIOUS DISEASES?

It really seems as if the medical practitioner was likely to find himself between the upper and the nether millstone in regard to the question of reporting cases of infectious and contagious diseases to his board of health. In our issue of November 19th, we published a very temperate note from the Chairman of the Boston Board of Health, reminding physicians gently but firmly of their neglect of duty under the act ordering the reporting of contagious diseases, to which the text of the act was appended.

In this issue of the JOURNAL, among the New York notes, our readers will find an account of steps taken at a meeting of the New York County Medical Society protesting against the treatment of two members, Drs. A. E. M. and A. S. Purdy, at the hands of the law, and providing for their defense in the Court of Appeal. In brief, the Drs. Purdy reported what they considered a case of varioloid to the New York Board of Health; the Board sent its inspector, who saw the patient and ordered her removal to the Riverside Small-pox Hospital. The case proved to be a light one, and the question was subsequently raised whether it had really been small-pox at all. The patient, a milliner, recovered perfectly and comfortably in a short time, but lately brought suit against the Drs. Purdy for \$10,000 damages to her business, pleading that she did not have varioloid. The jury awarded her \$500 damages.

The County Medical Society has very properly made the case its own. The question as to whether the woman actually had varioloid or not seems to have remained in doubt. There was, however, no doubt that the inspector of the Board of Health saw her and ordered her removal to the hospital, and at this point the responsibility of the attending physicians really ceased, whatever the view of the intelligent jury.

It is very important for the welfare of the community that physicians should report cases of contagious disease to the board of health, and should report them promptly; moreover the duty is in some States imposed by law. This is, however, one of many gratuitous services expected of doctors by their fellow citizens. If their fellow citizens make it more expensive to report than the rigor of the law would make it not to report, we imagine doctors will either abstain from reporting their contagious cases altogether or will not report them until they cease to have any element of doubt.

We hope this case in New York may be the means of bringing the law and common sense, or her sister, equity, nearer together.

### MEDICAL NOTES.

According to the latest bulletin of the Secretary of the Maine State Board of Health (November 28th) there have been only three cases of small-pox in that State during the summer and autumn, of which one was fatal and the other two were light varioloid.

— Dr. Squibb suggests as a means of disguising the taste of bitter and nauseous salines a mouthful of ice-water just before and just after the dose; the saline itself to be taken in a wine-glass full of ice water between them.

— The German Imperial Government has ordered the establishment of chairs for hygiene and bacteriology at all universities of the empire.

— Prof. C. A. Lindsley, M. D., has resigned the position of Dean of the Medical Department of Yale College, and Dr. Herbert E. Smith has been appointed his successor.

BOSTON.

— In the suit brought against Dr. W. H. Baker of this city, and the Free Hospital for Women, to which reference was made in a previous issue of the JOURNAL, the jury disagreed.

— The "hemorrhage man" to whom reference was made in these columns last week ran into the jaws of fate in quite a remarkable manner recently, and though it could not be said that he met with justice, he at least met with mercy in a quality that was not strained and a quantity that must have been rather overpowering. In front of an asylum in the suburbs of the city, whose artistic edifice he apparently took for the abode of some wealthy citizen, he fell and had his hemorrhage in full view of the occupants. Instantly there flocked forth an array of nurses trained in all the arts of first aid to the injured, with the accessories and extraordinary appliances for emergencies which the resources of an asylum might afford. His head was laid low, his chest covered with ice, salt, ice-water and ergot administered in generous quantities, and nothing omitted which lovely women in the enthusiasm of saving a life, could think of. Such as they had they gave freely, and the net results to the victim were much more abundant in treatment than in cash. It is surmised that henceforward he will shun anything that by any possibility could prove to be an asylum.

NEW YORK.

— At the meeting of the New York County Society held November 23d, a recommendation was made by the *Comitia Minora* that the Society should request Drs. A. E. M. and A. S. Purdy to appeal in a case in which they had been defendants. They had reported to the Board of Health a case of what they believed to be varioloid, and the patient was sent to the small-pox hospital, by the inspector of the Board. She has recently sued them for \$10,000 damages, on the plea that she did not have the disease, and the jury rendered a verdict awarding her \$500 damages. The *Comitia* also recommended that \$500, if necessary, should be appropriated to aid in the proceedings. On motion of Dr. C. R. Agnew, who, with others, expressed much chagrin that a physician should be fined for obeying the law in reporting contagious or suspicious cases of disease, the matter was referred to the *Comitia Minora* with power. Dr. Daniel Lewis,

who was re-elected President at the annual meeting in October, delivered his inaugural address, in the course of which he strongly advocated the establishment of a State Board of medical examiners. Dr. M. J. Roberts read a paper on the "Mechanical and Operative Treatment of Knock-knee and Bow-leg."

—The State Board of Health held its quarterly meeting in New York on the 16th of November. The report of the Executive Committee showed that the expenses for the year ending Sept. 30, 1885, were \$25,719.55. The work of bringing up averages in vital statistics has been satisfactorily continued throughout the year, and 51,800 certificates of births, deaths, and marriages have been thereby recorded. The Secretary, Dr. Carroll, reported what means had been adopted to ward off the introduction of small-pox from Canada; the principal efforts being made in the direction of calling into active existence the local health boards along the northern frontier of the State and insisting upon the immediate vaccination and revaccination of all unprotected at all exposed points within their jurisdiction. So successful have been the measures adopted, that small-pox has been reported in only eight localities outside of the cities of New York, Brooklyn, Albany and Yonkers, which are by law exempt from the control of the State Board. The only instance in any of these in which the disease was communicated to a second individual was one in which a nurse not properly protected by vaccination took it. The Board, as an additional means of protection, availed itself of the aid offered by the National Government through its Marine Hospital Service, and National inspectors have been placed along the frontier to inspect trains and other public conveyances coming from Canada, the undertaking being in charge of Dr. Austin, of the Marine Hospital Service, in consultation with the State authorities.

—At a meeting of the Medico-Legal Society held November 18, Prof. R. Ogden Doremus reported what he believed to be a case of fatal poisoning from the application of cocaine to an aching tooth. Dr. F. M. Thomas, a graduate of Bellevue College, had written him an account of the case, in which he found the patient, a woman, unconscious and dying from the effects of a medicine which she had been using for toothache. He also sent on to New York what was left of the drug, and on examination, it had proved to be hydrochlorate of cocaine. A general discussion of the effects of the remedy followed.

—The meeting held November 20 at the Academy of Medicine, under the auspices of the Charity Organization Society, for the purpose of devising measures to limit free hospital and dispensary treatment exclusively to the poor, was attended by a large number of prominent physicians and others interested in charitable work. Resolutions were adopted urging all the hospitals and dispensaries in the city to co-operate with the Charity Organization in weeding out undeserving patients, and a committee of six appointed to attend personally to the matter. On the Committee are three

physicians, Drs. S. O. Vanderpoel, J. West Roosevelt, and J. H. Emerson.

—The New York Post-Graduate School has fitted up a ward for sick infants in its building on East 20th Street, where it is designed to treat acute cases under two years of age. The ward will not be opened, however, until a sufficient sum has been subscribed to maintain twelve beds for two years.

—At a meeting of the Board of Managers of the Sanitary Aid Society for the Tenth Ward, the report of a lodging-house under the control of the Society showed that the number of lodgers for October was no less than 2,383. The cost of running the house is \$220 per month; but, notwithstanding the fact that much cleaner and more healthful accommodations are provided than is done by the ordinary cheap lodging houses, it is entirely self-supporting, and now yields a profit of seven per cent. on the original cost of fitting it up. It is contemplated by the Society to establish several other lodging-houses for men, and one for women.

—Dr. Wm. M. Smith, the Health officer of the Port, has been appointed to represent the Health Department of New York at the conference of health boards to be held at Washington December 8th.

—Typhoid fever is said to be unusually prevalent in certain portions of Brooklyn, the special cause for which does not seem to have been distinctly determined.

—Dr. Wm. Frothingham, a physician of large practice at Washington Heights, in the upper part of the city, and universally beloved and respected in the community where he lived, accidentally shot himself while cleaning a pistol on the 19th of November. He was fifty-five years of age, and graduated from the College of Physicians and Surgeons in 1851. After serving as an interne at Bellevue Hospital, he went abroad and further prosecuted his medical studies in France and Germany for three years. During the late war, he was surgeon of the Forty-fourth State Volunteers, Col. Ellsworth's regiment, and served as brigade surgeon under Generals Butterfield and Devin. For twenty years he practised at Washington Heights, and the funeral services were held at the Presbyterian church there. Among the pall bearers were Drs. Sands, Draper and Alexander, and the attendance was so large that the services of several policemen were required to keep the crowds back.

## Miscellany.

### THE BOY AND THE BONE SETTER

SPEAKING of bone setters recalls a good story which occurred in the north of Scotland, where one of them had risen to great fame and no small fortune by his skill. A country lad, residing a few miles off, had got his leg hurt at one of the local factories, and had been treated for some time by the local medical man without any good result. His mother, who had great faith in the neighboring bone-setter, wanted the lad to go

to him, which he declined, preferring, as he said, the "reglar faculty." Eventually, however, his mother's persuasions prevailed, and he agreed to allow himself to be taken to see Daniel R., the bone-setter. A bed for the invalid was extemporized on a cart, and, accompanied by his anxious mother, he was, after a painful journey, taken to the town where the bone-setter resided. The leg was duly examined, and it was found necessary to haul it very severely in order, as the bone-setter said, "to get the bone in." The lad was liberal with his screams while this was going on, but eventually the bone was "got in," and he was told to go home, and in a few days he would be all right and fit for his work. He was lifted upon the cart again, and with his mother seated beside him, set off for their home. "Didn't Danny do the thing well?" said the joyous old lady. "Yes, he did, mother," said the lad, "but I was na sic a fool as to gie him the sair leg!" The "reglar faculty" will, we have no doubt, appreciate the story. — *Whitehall Review*.

#### THE OPERATIVE TREATMENT OF CEREBRAL CLOTS.

A CASE of interest with reference to the proper treatment to have been pursued, is given in a paper, by Dr. C. B. Witherle, in the *Northwestern Lancet*, November 15th. The case was of a man who, while some-what under the influence of liquor, fell from the driver's seat of a truck, striking his head on a wheel as he fell. He walked a short distance and then became unconscious. He was taken to the hospital with symptoms of compression. There was no discharge from the ears. There was a scalp wound, but no depression of the skull was to be felt, though a crack was detected. Temperature 104°, pulse 80, hard, full and regular. A consultation of the staff was held and an exploratory incision being advised, the wound in the scalp was enlarged by a crucial incision and the bone freely exposed. The crack in the skull was found to extend forwards nearly in a straight line, across the coronal suture, being about four inches in length so far as exposed. There was no depression of the outer table, and it appeared evident that compression was produced by a clot. With the advice of the consultants the trephine was applied at a point about opposite the centre of the crack, and close to it on the side towards the median line. On removing the button a drachm or two of coagulated blood escaped from trephine hole, and was followed by a trickling of bright fluid blood. Careful exploration with a probe showed that a clot several inches in diameter and about half an inch in thickness remained. The only apparent effects of the operation were that the pulse rose to 120 and became softer, and that the Cheyne-Stokes respiration became more marked.

The practical question now came up as to removal of the clot. It was the opinion of the consultants that no further operative interference was advisable. It was argued that the pressure on the brain might be gradually relieved through the opening already made, and that any attempt to remove the clot would be likely to result in fatal hemorrhage from the wounded vessel. A bad prognosis was given, as there was held to be the probability of damage to the base of the skull by contrecoup. The author favored as a last resort the making of more openings, the removal of

enough bone so that the clot could be lifted out, and the attempt to stop the hemorrhage by ligature thermo-cautery, or otherwise. As this was not favored by the consultants, nothing further was done. The patient died the next day.

The autopsy showed an oval clot, six inches long and closely adherent to the dura, which was intact beneath it. The hemorrhage was discovered to have occurred from a branch of the middle meningeal artery. Underneath the dura just beneath the external clot was a clot of the size of an almond. There was no fracture at the base, or other lesion, except flattening of the convolutions from pressure.

In view of the results of the autopsy it seems possible that more radical operative interference might have saved the patient's life.

Dr. John B. Roberts, of Philadelphia, in his paper on "The Surgery of the Human Brain," lays down the following, as one of the articles of his creed: "Accidental or operative injuries to the cerebral meninges, meningeal arteries or venous sinuses should be treated as are similar lesions of similar structures in other localities." Bull, Parkes, Hopkins, Sands, Brinton and Nancrede are quoted as having had cases which support the truth of Dr. Roberts' assertion. In cases like the one related above, the most radical treatment appears justifiable, if it holds out the slightest prospect of success.

An interesting point in the case is that the Cheyne-Stokes respiration was apparently produced by transmitted pressure from the clot on the vertex. It is a common impression that this form of respiration indicates injury to the base of the brain, and that it contra-indicates operative interference.

Dr. Roberts in his paper already quoted mentions the Cheyne-Stokes respiration as a contra-indication to exploratory operation. He admits, however, in answer to a letter of inquiry addressed to him by Dr. Witherle that the wording is inaccurate, and that his meaning is "that if symptoms showed lesion to be in interior or at base of brain, operation was not indicated for that lesion. If there were an apparent fracture or sub-cranial clot, I should at once proceed to operate, as it would remove one of the possible causes of death."

Dr. Roberts, on commenting on the above case, of which the author sent him a brief account, says: "I would have enlarged the trephine opening and cleansed out all the clot."

#### Correspondence.

##### IMPORTANCE VS. IMPOTENCE.

PARIS, November 15, 1885.

MR. EDITOR. — The mistakes of printer and proof-reader during the past four hundred and forty years have undoubtedly caused as much amusement and vexation as any other known error of an innocent nature. In the majority of instances it is wise for writers to possess their souls in patience, but when a printer sets up *impotence* for *importance* and the proof-reader allows the word to stand, the writer sees the *importance* of overcoming the *impotence* which in such cases usually leaves him without resource, it being generally useless to correct a printer's mistake by a note to the journal, in which the error has occurred, after the article involved has been read and forgotten. In my case, however, I feel it to be due to Professor Weissmann, that the title of this fine dissertation which he read at the recent Congress in Strassburg be correctly given. Especially

so because the printer's error in question wholly reverses and destroys the meaning of the terms which Weissmann used. In my letter on the Strassburg Congress (see JOURNAL for October 29th), I mentioned Weissmann's paper on "The Importance of Generic Reproduction in the Theory of Selection." It is hardly necessary to say that the appearance in print of the word "impotence" in place of *importance* was (on behalf of Professor Weissmann, at least) somewhat amazing. "Impotence" is not only a very strong term, but, in its relation to the other words of the title of Professor Weissmann's paper is more than deserving of correction. In the original said title was: *Ueber die Bedeutung der geschlechtlichen Fortpflanzung für die Selectionstheorie.*

If Professor Weissmann believed sexual propagation *impotent* in its relations to the theory of selection, probably he would not have been invited to write this paper.

Yours very truly,

H. O.

At the time this mistake of our printers occurred, now more than a month ago, it proved both deplorable and laughable to ourselves and some of our intelligent readers, who by reference to the original title of Professor Weissmann's address anticipated our unfortunate correspondent's correction. We then felt that so palpable a mistake would be its own antidote, and also were impressed with our own impotence in the premises as an efficient alternative. — Ed.

# REPORTED MORTALITY FOR THE WEEK ENDING NOVEMBER 21, 1885.

Deaths reported 1,637; under five years of age 509; principal infectious diseases (small-pox, measles, diphtheria, and croup, whooping-cough, erysipelas, fevers, and diarrheal diseases) 282, consumption 265, lung diseases 117, diphtheria and croup 135, diarrheal diseases 14, typhoid fever 36, scarlet fever 17, malarial fever 16, whooping-cough nine, erysipelas eight, measles seven, cerebro-spinal meningitis seven, small-pox three, typhus fever two, puerperal fever one. From scarlet fever, New York six, Philadelphia four, Cincinnati three, Cambridge two, Haverhill and Brockton one each. From malarial fever, New Orleans six, Baltimore five, New York three, Philadelphia two. From whooping-cough, New York six, Philadelphia, Baltimore and New Orleans one each. From erysipelas, New York four, Providence two, Philadelphia and Boston one each. From measles, New York four, Boston, Baltimore and Haverhill, one each. From cerebro-spinal meningitis, New York four, Fall River two, Philadelphia one. From small-pox, New York three. From typhus fever, New York two. From puerperal fever, New York one.

Cases reported in Boston: diphtheria 13, scarlet fever 36, typhoid fever 17, and measles five.

In 108 cities and towns of Massachusetts, with a population of 1,290,794 (population of the State 1,911,650), the total death-rate for the week was 11.91 against 16.23 and 15.08 for the previous two weeks.

For the week ending November 7th, in the Swiss towns, there were 27 deaths from consumption, lung diseases 21, diphtheria and croup nine, whooping-cough five, measles two, small-pox one. The death-rates were: at Geneva 18.3; Zurich 17.5; Basle 18.1; Bern 20.7.

In the 28 greater towns of England and Wales, with an estimated population of 8,296,106, for the week ending November 7th, the death-rate was 19.9. Deaths reported 3,889, infants under one year of age 812, acute diseases of the respiratory organs (London), 391, measles 81, scarlet fever 18, whooping-cough 12, fever 12, diphtheria 18, diphtheria 10, small-pox (London and Liverpool) one each two.

The death-rates ranged from 15.5 in Halifax to 33.3 in Preston; Birkenhead 23.5, Birmingham 16.3, Blackburn 21.6, Hull 16.2, Leeds 18.6, Leicester 15.7, Liverpool 21.1, London 18.9, Manchester 27.1, Nottingham 20.0, Sheffield 19.6.

In Edinburgh 14.07; Glasgow 21.2, Dublin 23.5

The meteorological record for week ending November 21st, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole of the United States Signal Corps:—

Week ending	Barometer.		Thermometer.		Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather.			Rainfall.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM NOVEMBER 21, 1885, TO NOVEMBER 27, 1885.

HEGAR, ANTHONY, surgeon and major. Member of the Army Medical Examining Board now in session in New York City, is relieved from the additional duty of attending surgeon in that city, to take effect when Lieutenant Colonel Jos. R. Smith, surgeon, shall have arrived in New York and entered upon that duty. S. O. 257, A. G. O., November 19, 1885.

REED, WALTER, assistant surgeon and captain. Granted leave of absence for one month, with permission to apply for one month's extension, to take effect about December 1, 1885. S. O. 115, Department of Platte, November 18, 1885.

TAYLOR, ARTHUR W., assistant surgeon and captain. Granted leave of absence for one month, to take effect December 5, 1885. S. O. 116, Department of Platte, November 20, 1885.

CHAPIN, A. R., assistant surgeon and first lieutenant. Ordered for temporary duty at Fort Robinson, Neb. S. O. 115, Department of Platte, November 18, 1885.

SIMONS, JAMES, lieutenant colonel (retired), died November 11, 1885, at Baltimore, Md.

#### OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING NOVEMBER 28, 1885.

MURKIN, R. A., surgeon. Detached from Marine Barracks, Washington, D. C., December 7, and wait orders.

MOORE, A. M., surgeon. Ordered to Marine Barracks, Washington, D. C., December 7, 1885.

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE FOR THE WEEK ENDING NOVEMBER 21, 1885.

YEMANS, H. W., passed assistant surgeon. Promoted to be passed assistant surgeon from November 1, 1885, November 11, 1885. Re-assigned to duty at San Francisco, Cal., November 16, 1885.

McFETTER, W. P., assistant surgeon. Appointed an assistant surgeon, November 11, 1885. Assigned to duty at New Orleans, La., November 16, 1885.

#### SOCIETY NOTICES.

BOSTON SOCIETY FOR MEDICAL OBSERVATION. A regular meeting of the Society will be held at the Medical Library, 19 Boylston Place, on Monday, December 7th, 1885, at 7 1/2 P. M. Readers: Dr. S. W. Driver, "Non-Puerperal Uterine Hemorrhage, with a List of Cases, treated by a New Remedy." Dr. R. H. Fitz, "Inflammation of the Vermiform Appendix." Balloting on Candidates for Associate Membership at 9 P. M.

H. L. BIRRELL, Secretary.

MASSACHUSETTS MEDICAL SOCIETY, SUFFOLK DISTRICT. The Section for Clinical Medicine, Pathology and Hygiene will meet at 19 Boylston Place, on Wednesday, December 9th, at 7 1/2 o'clock. Papers: Dr. G. M. Garland, "Some Cases of Reflex Neurosis." Dr. H. C. Haven, "The Etiology of Rachitis." Dr. F. B. Harrington, "Pulmonary Complications in Typhoid Fever."

ALBERT N. BODDITT, Secretary, 138 Boylston St.

GYNECOLOGICAL SOCIETY OF BOSTON.—The next regular meeting will be held at the Medical Library Rooms, No. 19 Boylston Place, on December 10th, at 4 o'clock, P. M. A paper communicated by Dr. A. Martin, of Berlin, on "Ectasies in the Cervix, and Roof of the Vagina," will be read by Dr. E. W. Cushing.

H. J. HARRIMAN, Secretary.

#### BOOKS AND PAMPHLETS RECEIVED.

Aids to the Obstetrics (Double Part). By Samuel Hall, B.A., M.D., Cantab, etc. New York and London: G. P. Putnam's Sons. 1885.

Intubation of the Larynx, with History of Cases. By F. E. Waxham, M.D., professor of Diseases of Children, College of Physicians and Surgeons of Chicago. Read before the Chicago Medical Society, October 5, 1885.

Elements of Organic Chemistry, Descriptive and Qualitative. By James H. Shepard, Instructor in Chemistry, Ypsilanti High School. Boston: Published by D. C. Heath & Co. 1885.

Transactions of the American Otological Society. Eighteenth Annual Meeting. Report House, New London, Conn., July 14, 1885. Vol. III, Part 4.

The Principles and Practice of Medicine. By the late Charles Hilton Fagge, M.D., F.R.C.P., Physician to, and Lecturer on Pathology at Guy's Hospital, etc., including a Section on Cutaneous Diseases, by P. H. Pye-Smith, M.D., F.R.C.S., Chapters on Cardiac Diseases by Samuel Wilkes, M.D., F.R.S., and Complete Indexes by Robert Edmund Carrington, M.D. Vol. I. Philadelphia: P. Blakiston, Son & Co. 1886.

An Atlas of Clinical Microscopy. By Alexander Peyer, M.D. Translated and Edited by Alfred C. Girard, M.D., Assistant Surgeon, United States Army. First American, from the Manuscript of the Second German Edition, with Additions. New York: D. Appleton & Co. 1885.

Lectures on the Diseases of the Nose and Throat. Delivered during the Spring Session of Jefferson Medical College by Charles E. Sajous, M.D., Illustrated. Philadelphia: F. A. Davis, Ait, Publisher. 1878.

The Metric System in Medicine. By Llewellyn Eliot, M.D. Washington, D. C. (Reprint from Medical Record, October 17, 1885.)

Report of the Surgeon General of the Navy for the Year 1885. Washington Government Printing Office. 1885.

Ueber Varicen von Dr. L. Von Lesser Privat Dozenten für Chirurgie in Leipzig. (Separatabdruck aus Virchow's Archiv für Pathologische, Anatomie und Physiologie, und für Klinische Medizin. 101 Band. 1885.)

A Manual of Microscopical Technology for Use in the Investigations of Medicine and Pathological Anatomy. By Dr. Carl Friedländer, Berlin. Translated with the Express Permission of the Author from the Second Enlarged and Corrected Edition. By Stephen Yates Howell, M.A., M.D., Buffalo, N.Y. New York and London: G. P. Putnam's Sons. 1885.

Psychiatry, a Clinical Treatise on Diseases of the Fore-Brain, Based on a Study of its Structure, Function and Nutrition. By Theodor Meynert, M.D., Vienna. Translated under Authority of the Author, by E. Sachs, M.D., Instructor in Diseases of the Mind and Nervous System in the New York Polytechnic. Part I. The Anatomy, Physiology, and Chemistry of the Brain. New York and London: G. P. Putnam's Sons. 1885.

Facts and Mysteries of Spiritism; Learned by a Seven Years' Experience and Investigation, with a Sequel. By Joseph Hartman. Philadelphia: Thomas W. Hartley & Co. 1885.

## Original Articles.

THE SPECIFIC AND INFECTIOUS CHARACTER OF TUBERCULOSIS, WITH EXHIBITION OF THE BACILLI OF TUBERCULOSIS, AND THOSE OF MALIGNANT PUSTULE (ANTHRAX).<sup>1</sup>

BY E. W. CUSHING, M.D., OF BOSTON.

In considering the etiology of tuberculosis, facts have often been observed suggesting that it is infectious, and, in fact, the question was discussed here some years ago, when many cases were related, supporting this theory. But, although this view is very old, and has long been popular in some countries, especially in Italy, yet it certainly never took firm root in the profession until recently, when Professor Koch furnished proof of the directly infectious nature of the disease. I have been asked to give a summary of the evidence on which his decision rests, and shall therefore make a free use of his work on the subject, published in the last communications of the German Imperial Health Office. Although the question will seem rather threadbare to many of you, the importance of the subject is so great that I ask you to bear with me while I go over this ground, as requested.

To determine this question of infectiousness there are three courses possible, either first to rely on clinical facts — and these have never been clear enough to convince the profession; second, to study the subject in the light of pathological anatomy; and third, to try to get light from experiments. The second method has given us many facts, notably, that miliary tuberculosis generally can be traced to preëxisting caseous deposits, showing an auto-infection; in some cases the direct manner of the general dispersion of the tubercles can be seen, as shown by Ponfick, to depend on the introduction of tuberculous matter into the thoracic duct, or as observed by Weigert, where similarly the wall of a bloodvessel allowed a direct introduction of caseous deposits into the general circulation. An auto-infection was thus demonstrated, but the cause of the original disease was not explained.

The method of experiment was used by Klenke in 1843, to show that rabbits could be made tuberculous by inoculating into them the sputa, or fragments from the lungs, of tuberculous patients, and these experiments were improved and extended by Villenun, Klebs, and others. But, on the other hand, it was shown that animals died from similar affections after the injection of fragments of powdered glass, etc., and it was long before it was demonstrated that in such cases where the creatures were really tuberculous, it was owing to the contamination of the matters injected with the virus of other tubercular animals, or to the infection derived from keeping them in confined localities with other creatures already affected, or in cages where such had been affected with the disease.

It is now well known that no animal can be made tuberculous by substances which have been properly sterilized, and which are inoculated under proper antiseptic conditions.

The clearest and prettiest example of infection was furnished by the experiments of Cohnheim and Salomonsen, who inoculated the anterior chamber of the eye in rabbits with material from tuberculous subjects.

This experiment has the great advantage that spontaneous tuberculosis of the eye in rabbits never occurs, and that the whole process can be watched, as the little tubercles form on the iris, become caseous, and infect the whole eye; then they creep along the lymphatic vessels, and infect the glands of the neck, and thence the liver, lungs, spleen, etc. No substance not from a tubercular source, or which has been sterilized, will do this, and the demonstration of infection is complete.

That chapter is closed, and it remains to find out the nature and properties of the cause of the infection.

This might either be something formed in or from the body, organized or unorganized, or a parasite from without, living in the diseased tissues, and reproducing itself there.

As no one had ever been able to find or demonstrate a virus of the first kind, it seemed reasonable to search for one of the second, and it is the great honor and service of Koch to have solved this problem.

He was led up to his discovery by the analogy of infectious processes everywhere, as best exemplified by anthrax or malignant pustule. As this is the very type and sample of infectious diseases I will be somewhat more explicit.

If the blood or organs of an animal dead of anthrax be examined with a reasonably good microscope, it is found to swarm with little rods, single or jointed together, but having no proper motion. This is an invariable accompaniment of the disease, but not therefore necessarily its cause. It is found, however, that they grow readily on gelatine mixture, or boiled potato, and by various processes of coloring the cultures so produced, these rods are seen to enclose spores.

Now the smallest scratch on a healthy animal if inoculated with the blood of one suffering with anthrax, will set up the disease in the former, if of a species susceptible of it, and with fatal effect, and when it dies, the rods are found in its blood, or organs, as I here show you, having lost none of its peculiarities. Still it might be said that the rods did not cause the disease, but some other product contained in the blood set up the infection, and rendered the infected animal a fit soil for the growth of harmless parasites. But if these rods be bred, say on potato, from one generation to another, taking each time a very minute portion on a needle for seed, it is plain that after a few generations nothing is left except the bacilli, and not even any of those which came from the first diseased animal, but only their remote posterity or descendants. Here I show the rods in a pure culture, many times removed from the first, and showing a network of chain-like rods, jointed together like chains, and containing spores which do not take the color.

Now the smallest portion of a culture like this inoculated into an animal, of a susceptible species, will set up the disease in all its original virulence, showing that the bacilli or rods are the cause and not merely the accompaniment of the disease. The actual poisoning is supposed to come from a chemical virus which they excrete, but the exact manner of their action is not essential; we say they cause death as we say that a bullet causes death when shot into the chest, without necessarily knowing the exact way in which it acts. Practically no one doubts this virulent activity in the case of anthrax; it cannot be explained away, there is no chance for error, and it naturally points the proper course for experiments with other diseases.

<sup>1</sup> Read before the Section for Clinical Medicine, Pathology and Hygiene of the Suffolk District Medical Society, November 11, 1885.

Koch, therefore, set himself to find out whether there exist in the blood, organs, or sputa of the tuberculous any formed elements not belonging to the body, or derivable from its tissues.

If such were found, to determine whether they had motion, or other signs of life, such as reproduction, subdivision, formation of spores, etc.

Whether they could be cultivated outside the body, and isolated by repeated cultures, and, if so, whether they alone are capable of causing the disease, as the bacillus anthracis causes anthrax.

Now Koch was not the first who had thought of this: many had looked for bacteria in tuberculosis, but had not found them. A common microscope will scarcely show them, when stained, far less find them uncolored among the morbid tissues.

Remembering that the addition of potash to aniline dyes facilitates the coloring of certain bacteria, he tried an alkaline solution of methylene blue, and was fortunate enough to get the bacilli tuberculosis faintly stained, and found that, very luckily, when the preparation is put into a brown solution of vesuvin, the bacilli stay blue and the other substances present become brown. The process of staining was afterwards modified and improved by Ehrlich, Weigert, and others, and carried to the precision of a chemical reaction, so as to distinguish infallibly between the tubercle bacilli and any others yet discovered.

The only bacilli liable to cause confusion are those of lepra and of syphilis, and where doubt might exist, which is very seldom, there are means of distinguishing them, which we need not enter on here.

The method at present recommended by Koch, probably the surest, is as follows: aniline water is prepared fresh by shaking five cm. of pure aniline oil with 100 cm. of distilled water, and filtering well through a wet filter paper, to make a clear solution. To 100 cm. of this is added 11 cm. saturated alcoholic solution of methyl violet or of fuchsine and 10 cm. of absolute alcohol. This solution will keep for about ten days if well stoppered. In this solution fine sections of organs hardened in absolute alcohol must lie twelve hours or more; fluids dried and baked on to cover glasses can be stained in ten or fifteen minutes by heating the solution nearly to boiling. The preparations are then put for a few seconds in a twenty-five per cent. solution of nitric acid, until they lose most of their color, and well washed in sixty per cent. alcohol. They are then stained in a dilute solution of vesuvin (for methyl violet) or of methylene blue (for fuchsine) washed again in sixty per cent. alcohol, have the water taken out by absolute alcohol, are cleared up by cedar oil, and can then be examined microscopically, or if desired can be preserved in Canada balsam.

There is nothing very difficult in all this for one who has a moderate skill in using a microscope and making preparations, but of course it takes a little time, and some patience to learn to handle the colors properly, so as not to decolorize too much, nor smother the bacilli in the contrasting color.

Sputa can be kept in a stoppered vial for weeks, if necessary, without injuring the bacilli, or can be dried in a thin layer upon covering glasses, by squeezing a drop between two glasses, sliding them apart and drying them well. They can thus be kept for a long time until occasion offers for a proper examination. But even when stained and prepared it requires a good microscope to see them, and especially to find them in

tissues. To work at all satisfactorily a microscope is necessary, having a large condensing lens underneath, which concentrates a flood of light from all sides on the colored bacilli, at the same time rendering all the tissues indistinct and hazy by abolishing all shadows.

Moreover, it is desirable to have a good oil immersion object-glass of one-twelfth or one-sixteenth, giving a magnifying power of 700 to 1000. With such a microscope I show you bacilli from tuberculous sputum and from the secretion of a little cavity in a lung, also in the tissue of the same lung, and in a tuberculous larynx.

In the lung I show you, with a power of only fifty, the bacilli lying in a mass so dense as to give a red blot on the pale blue ground, and by a higher power you can see the individual bacilli; a slight motion of the adjusting screw causes them to appear to squirm as various layers rapidly pass into and out of the focus.

I exhibit also the plates of the work of the Imperial German Health Office above referred to, showing how they lie singly, or a few together, in the giant cells, which have long been noticed as characteristic of tubercle, apparently imprisoned there; how they lie in dense masses in the walls of cavities, around small arteries, in the kidneys, etc. You also see here representations of the organs of animals dead of acute general tuberculosis, from inoculation or inhalation, of which I will speak presently.

Here, then, is our specific bacillus; it remains to see first, if it is always present; second, if it can be bred and isolated; third, if it can cause the disease; and fourth, if anything else can set up tuberculosis. To settle these points long series of experiments have been carried on, covering years of precise and conscientious labor, of which I can only cite a few from the book you have in your hands, merely stating that I have seen many of them repeated, and have repeated some myself, and I heartily believe in their entire accuracy and fairness.

To detail even a fraction of the experiments connected with this investigation, would take me far beyond the limits of this paper; I can only sketch methods and results, referring you to the original reports for judgment as to the thoroughness and accuracy with which they are made.

The bacilli were sought and found in all manner of tubercular products both in man and in animals. They are from one-fourth to one-half the diameter of a red blood corpuscle in length, and relatively in thickness about in the ratio of pieces of a common lead pencil which has been cut into three or four pieces. But absolutely it is the length and not the thickness of the bacilli which varies. They carry spores from four to six in each bacillus, when they occur, but they are not always found. In cheesy masses they are seldom found, either because they are not there, or because like the spores, which never take up the color, they cannot be stained. That the spores at least are present in the cheesy masses is shown by the highly infectious properties of the latter when inoculated into animals.

It is interesting to find that the bacilli are always precisely similar, whether found in man or animals, in milary tubercles, in sputum, or in cavities, in scrofulous glands, so called, or in tuberculous joints. Even in lupus, the bacillus is in no way different, and can be bred in cultures, and when so bred and inoculated into animals it promptly sets up general tuberculosis.

The bacilli have no proper motion, and in their migrations they are carried along by wander-cells and so pass into the lymphatic system. The cells which carry them soon lose their properties, and either are arrested and surrounded by epithelioid cells, or, as Koch thinks more probable, they are deformed and changed to giant cells, enclosing their bacilli.

I will not weary you by rehearsing the different kinds of cases of phthisis, and scrofula, in which bacilli have been demonstrated. Koch describes the examination of nineteen cases of military tuberculosis of various organs, in all of which bacilli were found, and in no case were they wanting. In twenty-nine cases of pulmonary phthisis examined they were in no case absent, and this fact is of great importance as opposed to the view of those who hold that a large class of cases of phthisis are independent of bacilli, and that the latter are only an accidental complication of an existing disease.

Of course the fact that bacilli are not found in the sputa is no evidence that they are not present in some parts of the lung, not opening directly into a bronchus. Even in a post-mortem examination it requires a real expert in a doubtful case, to select the portions of lung to be searched microscopically, and even in the same little piece not every cut may have bacilli.

But admitting that cases do occur where phthisis exists and no bacilli can be found in the sputa, they are *very rare* when due diligence is used, and, on the other hand, where the bacilli are found it is a clear proof of tuberculosis.

In scrofulous glands and joints, which show the characteristics of tubercle, namely, collections of epithelioid cells or giant cells, the bacilli were found in all cases examined, namely: twenty-one cases of scrofulous glands and thirteen of scrofulous joints.

This does not deny that the glands may undergo enlargement from other causes and microscopically simulate scrofula. In four cases of lupus where sections of the skin were examined, the bacilli were always present, although in one case twenty-seven cuts, and in another forty-three cuts, had to be searched in order to find the bacilli. Even in one of these cases pure cultures were bred in serum, which, when inoculated into animals in the anterior chamber of the eye, set up tuberculosis, as likewise did the fresh matter in every one of seven cases.

From the various cases mentioned above, and from many others occurring in man or animals, there were inoculated, or infected, a total of five hundred and nine small animals, of various genera, which died tuberculous, and in these, without exception, the bacilli were found in the tubercles.

In general, then, in all cases, human or animal, which showed both in their history and on microscopic examination, that they were truly tubercular, there were found characteristic bacilli, showing a peculiar and distinctive reaction with aniline colors. The whole number was so large that this could not be accidental. To be precise, there were two cases in the whole number in which the bacilli could not be found directly, namely, the pus of a nephritic abscess, and the pus of an abscess arising from caries of the vertebra. In both these cases, however, the pus caused tuberculosis when inoculated into animals, and, doubtless, if the kidney or the vertebra could have been searched, the bacilli would have been found in them. Moreover, all sorts of diseases in men and animals were carefully

studied, but in none were the above bacilli found except in true tubercular processes.

*Secondly.* The presence of the bacilli characterizes the inception of the disease, it is the first step in the formation of the tubercle: it is found that the first collection of epithelioid cells, and of a giant cell, coincides with the deposit of a bacillus, the caseation comes later.

*Thirdly,* where the disease is active, the bacilli are numerous, and vice versa. When the phthisis is chronic they are few and scattered, when it ceases, and the lesions heal, the bacilli disappear, both from the sputum and tissues.

Koch insists that these three facts, namely: "that the tubercle bacilli invariably and exclusively accompany tuberculosis; that, both in locality and time, they precede all the peculiar pathological changes of that disease; and that their number, their presence, and their disappearance, stand in direct relation to the course of the tuberculosis — that these facts permit us to conclude, with great probability, that the bacilli tuberculosis are no accidental accompaniment of tuberculosis, but that they stand in a *causal* connection to it.

But the question is so important that I shall ask you to listen to the further experiments made, as before suggested, in order to cultivate and isolate the bacillus, and to ascertain, with full certainty, its infectious properties.

Of course the first attempts to cultivate the bacilli were made with the ordinary mixture of meat, water, peptone and gelatine. But they did not grow because the temperature at which the gelatine mixture ceases to be solid is far below that necessary for their development. Blood serum, however, when heated to 65° C., becomes solid and yet is transparent, or nearly so. First, however, it must be heated daily for five consecutive days to 58° C. for an hour, to kill all bacteria present as they come out of the condition of spores. On the surface of the serum, the particles of suspected tissue are laid, and the bacilli soon spread out in a thin white layer. Of this a minute particle is taken on a platinum wire, which has been heated previously to redness and then cooled, and is quickly laid on the surface of another layer of serum in a test tube, and this is then stoppered with cotton; after a few such transplantings it is certain that practically none of the original material is left. Koch gives a table of forty-eight sets of cultures derived from all possible sources in tubercular men and animals.

There are also long series of experiments on animals made by inoculating the tuberculous tissues or cultures, or mixtures of them, with water, into the eye, veins, peritoneal cavity, under the skin, etc., also infections by feeding and by inhalation. I will not detain you with these. In general, I may say that the lymphatic glands nearest the point of inoculation became swollen and caseous, and from them in time arose a military tuberculosis of the liver, spleen, kidneys, lungs, etc.

In the plates you will see the organs represented, covered with the military tubercles. I will only describe one experiment by inhalation, as this is the form of infection to which man is most exposed; it will also show the thoroughness with which the experiments were carried on. Culture No. 1 was obtained from human pulmonary phthisis, first by inoculation of a guinea-pig, thence planted in serum and carried to fifteen months in twenty-three transplantations. It was rubbed with distilled water and diluted out in a

seemed nearly clear. The upper clear part was decanted and used for inhalations by atomizing daily for three consecutive days, each time for a half hour, fifty cubic centimeters, into a cage containing eight rabbits, ten guinea-pigs, four rats, four mice. As it would have been too dangerous to do this in a house or to be in close proximity to the spray, the cage was placed in an open garden and the air was forced to the atomizer through a small lead tube run in through the casing of a window which was kept shut. After the inhalation, the animals were separated and put alone in roomy cages.

In ten days some of the animals had dyspnoea, between the fourteenth and twenty-fifth days three rabbits and four guinea-pigs died. All the other animals were killed on the twenty-eighth day.

Every one of the twenty-six animals had tubercles in the lungs, and those who died latest or were killed had them also in their livers and spleens. The rats and mice being less susceptible had less abundant lesions, but there was no doubt about any of them. I show a picture from the lung of one of the rabbits, showing a cheesy pneumonia, quite similar to the spontaneous tuberculosis so-called of these animals which is really an infection by inhalation.

From these various animals, tuberculous matter was taken and inoculated subcutaneously on the bellies of twenty-two guinea-pigs. They all soon had swelling of the inguinal glands and all died tuberculous in from five to eight weeks.

In the various inoculations and inhalations all the animals used, of susceptible species, two hundred and seventeen in number, became infected and died. A large number of other animals had similar inoculations performed with fluids free from the tubercle bacillus and none were affected; nothing else produced the specific disease except the tubercular matter, or cultures from it, the latter working more promptly.

All sorts of other bacteria were tried, with negative results, all errors were avoided, every care taken.

There is no escape from the conclusion that the third and fourth of the above mentioned questions are satisfactorily answered. Tuberculosis is to be classed in the category of infectious diseases, as much as anthrax. The bacilli tuberculis are as much the cause of the former as the bacilli anthracis are of the latter.

The next point to consider is the manner in which bacilli are reproduced, and how they enter the body to produce infection. Now as they will not breed at a temperature less than 30 C. or 80 F., it is evident that they cannot find this temperature enduring for weeks together, combined with moisture and an animal substance to serve for nourishment, except in the animal body during life. They are not, therefore, like the germs of anthrax and erysipelas, which are capable of living and breeding entirely separate from any animal organism. Every tubercular infection must come directly from some previously diseased person or animal. This can occur in three ways: *First*, by inhaling the bacilli or their spores, either in spray or dust derived from the sputa of the phthisical. *Second*, by inoculating wounds or scratches with similar material, causing a glandular tuberculosis or scrofula, which, when the original abrasion has healed, seems to have arisen spontaneously. *Third*, by swallowing meat or milk coming from tubercular animals.

In support of this view it is only necessary to recall the vast amount of matter expectorated by the phthisi-

cal, who comprise nearly one-seventh of civilized humanity. Experiments show that the bacilli do not lose their virulence in sputa which has been allowed to stand and putrefy for seven weeks, that when dry, they are infectious after six months. They have been demonstrated in the milk and even in the blood of diseased animals, and it is proved that tuberculosis can be induced in animals by feeding them with milk and other material from tuberculous animals. A case is on record where a phthisical wet nurse gave tuberculosis to three successive infants which she suckled.

All this, however, it will at once be observed, proves too much; why do we not all become infected, since we must all be exposed?

In regard to the milk and meat question, it is because cows' milk rarely becomes tuberculous unless the udder is diseased, and it so happens that this is seldom the case, for the tubercular nodules are usually confined to the lungs, or at least to parts not used as food, because rejected when manifestly diseased. Moreover, the healthy stomach seems able to destroy the bacilli, even when not previously killed by cooking of the meat eaten. The bacilli, also, do not, as a rule, remain long enough in the intestines to acquire a lodgment. In phthisical persons, however, who swallow their own sputa to a certain extent, it not infrequently happens that the intestines become tuberculous by a real autoinfection.

As for infection from scratches, the great safety lies again in the long time required for the development of the tubercle bacillus, and perhaps in the low temperature of the outermost layers of the most exposed portions of skin. The question is not yet sufficiently examined to make it worth while to discuss it at length here.

However desirable it may be then to reform our meat and milk supply by proper inspection and regulation, practically the great source of tubercular infection is by inhalation, as is evident from the fact that the lungs are first attacked in the great majority of cases.

Here, again, the principal objection to accepting the theory of infection is the fact that we do not all die of the disease. But in the first place a great many do so die, so many that a scare over a little small-pox or even cholera seems absurd in view of the fearful mortality of one in seven from phthisis.

Why do the rest escape? Because not only the seed is requisite, but the soil must be adapted to it; in other words, there must be a predisposition, or, at least, a susceptibility.

Just as some species of animals are far less liable to "take" an infection than others, and individuals of the same species vary more or less, so in man certain persons and certain families, even certain races, show a marked immunity as compared with others who seem predestined for infection.

Not every child "takes" scarlet fever when exposed, nor measles, nor vaccination, so not every person "takes" tuberculosis. It must be remembered that the living and healthy organism fights against infections of all kinds of bacteria; it is not like a test-tube of serum; it has its own proper vital defences. Some of these we understand, some we do not. In regard to this specific infection, we observe at once the great advantage that it is to us that the bacilli do not reproduce themselves for ten or fifteen days, so that if

the lungs are healthy, there is every chance that they will be caught and passed upwards by the ciliated epithelium until they can be coughed out; on the other hand, we see why infection so readily occurs when the cilia are damaged or lost, as after measles or catarrhal conditions, or when, for any reason, there are collections of secretions retained in the lungs, forming a nidus for the bacilli, or when, owing to imperfect development or deformity of the thorax, or pleuritic adhesions, the movements of the lungs are so restrained that foreign particles and catarrhal secretions are imperfectly and slowly removed.

Practically, therefore, it is found that infection usually only takes place where there is family predisposition, abnormal pulmonary or thoracic development, or pre-existing disease of the bronchial mucous membrane.

The other predisposing causes are apt to be intemperance, weakness, hunger, or close confinement in workshops or dwellings, where the system of previously healthy persons is reduced and they are rendered susceptible to infection. Of course, if in addition to close quarters there is the presence of a tuberculous person continually coughing bacilli into the air, and covering the floor and furniture with spores which are frequently stirred up as dust, we have pretty accurately reproduced the experiment of the cage and atomizer to which I referred above. Who can wonder that under these circumstances the infection spreads in families and workshops?

But if a bacillus gains a lodgment and begins to breed, what follows? In susceptible cases, the same process goes on which we have followed in the rabbit's eye. The infection creeps along, carried by wander-cells from point to point, from gland to gland; the carrying cells are deformed to giant cells, surrounded by epithelioid cells. These become cheesy, large nodules form, caseate, break down, open into a bronchus and are expectorated, forming a cavity; often some of the secretion is aspirated into neighboring parts, and wherever it comes, sets up a cheesy pneumonia; sometimes, by passing into the blood-vessels or thoracic duct, the bacilli pass into the general circulation and set up a general acute miliary tuberculosis.

But all cases do not take this dismal course; sometimes nature triumphs over the invader. Man is not a rabbit or a guinea pig. In resistance to tubercular infection, as well as in other characteristics, he partakes of the peculiarities and privileges of his friend, the dog. In many cases then, the bacilli find that they are in an unfruitful soil. The wander-cells bearing bacilli are arrested, headed off by a general concurrence of leucocytes; a barrier is formed around the budding tubercles, and they stay imprisoned until the bacilli die; or, if the mass is larger and caseates, and is expectorated, the boundary contracts, the bacilli diminish in numbers, fewer and fewer, and finally none are found in the sputa, and the patient recovers, bearing in his lungs the scars that are so often found on autopsy.

From the frequency with which these cicatrices are observed, these cases of recovery must be very common, and often occur where tuberculosis was not suspected or diagnosed, or where, because the patient got well, the physician has been blamed for mistaking the nature of the malady, when he might have deserved praise for curing a case of consumption.

You all know how, in a broken-down cachectic subject, a common micrococcal infection will spread in the

subcutaneous tissue, causing a wide-spread, perhaps fatal cellulitis, whereas, in a healthy subject, the intruders are fenced off by a wall, a pyogenic membrane as it used to be called, holding them back until they die or are eliminated. Quite analogous to this is the action of the tissues in fighting and fencing out the tubercle bacillus, and hence the explanation of the fact, long known and acted on, that general treatment, good food, pure air, out-door life, etc., etc., are the great aids in combating the disease.

I will say nothing here as to the means of treatment suggested by the discovery of the true nature of tuberculosis, merely remarking that this is no empty theory, but will bear fruit in the actual treatment of disease.

I have a few words, however, to say in regard to the sputa. It is evident that these should be carefully disinfected and rendered harmless. A thoroughly exhaustive series of experiments by Schill and Fischer, show that the best means for disinfecting the fresh sputa is to have in the spit-cup a quantity of five per cent. solution of carbolic acid equal in amount to that of the sputa. Sublimate solution is not sufficient, because it acts only on the outside of the lumps of sputum, cooking them, so to speak, but not killing the bacilli on the inside. Baking or boiling of handkerchiefs or clothes which have been soiled will kill the bacilli in an hour, even when the clothes are thick.

I submit that an organized public opinion ought to be brought to bear against the disgusting habit of spitting on the floor of horse-cars and public places, and physicians certainly ought to attend to such matters in prescribing the hygiene and mode of life of their patients, especially among the poor and ignorant.

The frequent examination of the sputa is of the utmost importance in establishing the diagnosis, and very useful in watching the progress of the disease. There is no doubt that bacilli can almost always be found before the tuberculosis has made much progress, and the gradual diminution of their frequency and their final disappearance is the surest token of recovery. Galky has published the results of the investigation of fourteen cases, examined microscopically daily for some three months; of twelve patients' sputa, there were in all nine hundred and eighty-two examinations, each time of one slide from each patient daily. Bacilli were found nine hundred and thirty-eight times, and not found forty-four times. Most were severe cases, but some were without fever and had only slight infiltration of the apices, yet the bacilli were found in the latter.

In two cases, the bacilli diminished, were absent, returned, and finally disappeared altogether; one of these was discharged apparently cured; the other died of peritoneal peritonitis caused by swallowing eighteen plum-stones. The lungs showed no exens or cheesy deposits, but a calcified spot as large as a cherry stone, and slate-colored, fibrous induration of the apices.

I will only insist, on closing, on the great necessity for the disinfection of tuberculous sputa; for proper precautions to prevent infection of relatives or attendants of the phthisical; of the careful examination of our meat and milk supply, and of carefully treating any catarrhal conditions of the air-passages, as well as of generally keeping the system of those up to par who have any inherited disposition to tuberculosis.

Of the regular examination of tuberculous or suspected sputum, I will only say that it must become more and more common, like auscultation and percus-

sion, until it becomes an essential part of every examination of the chest, making any pretence to thoroughness or scientific precision in patients suspected of tuberculosis.

# A CASE OF PHTHISIS WITH NUMEROUS BACILLI. COMPLETE ARREST OF THE DISEASE.

BY VINCENT V. BOWDITCH, M.D.

OWING to the universal discussions which have been carried on in the medical world during the past year or two over the bacillus tuberculosis, the following case will, I think, be of interest to you this evening, and if I present it to you rather in detail, I trust I may be pardoned, as it is for the purpose of seeing, if possible, what deductions can be drawn from it as to the significance of bacilli in the sputa of phthisical patients.

On June 20, 1883, I was called to see Miss H—, a young lady aged twenty-three, who gave the following history: Always remarkably strong and well, with the exception of a severe "congestion of the lungs of short duration when a baby." All of the bodily functions had been perfectly regular. The father, mother and the whole family were healthy people without history of lung trouble in any branch. During the previous winter the patient had interested herself greatly in photography and had had one or two severe headaches which increased in number and severity during the few weeks previous to my visit, and four or five weeks before, a slight hacking cough had begun with greenish sputa. A rapid and marked loss of appetite, flesh and strength together with feverishness, occasional night sweats, and increasing languor, after a visit to the seashore, so alarmed her mother that she felt a physician must be consulted immediately.

The patient was tall, of fine physique, the face somewhat pale, with a languid expression, the whole appearance being that of one accustomed to robust health, but temporarily indisposed. The voice was slightly hoarse. Upon physical examination I found very marked dullness at the right apex above and below the clavicle extending down to about the second intercostal space, and auscultation revealed very numerous loud, moist rales, with prolonged expiratory murmur and decided "nearness of voice" in the region of dullness. Once or twice there was a suspicion of a "squeak" in the left apex. Elsewhere in the chest the physical signs were normal. The temperature was 100.2 and the pulse 94.

Nourishment was ordered in the form of milk to be given every two hours with Murdock's Food, and the patient was told to take Fellows' Syrup of the Hypophosphites, to paint over the region of dullness with Tincture of Iodine for several weeks, and to inhale once or twice a day a mixture of equal parts of Tincture of Opium, Tincture of Hyoscyamus and Tincture of Conium, the inhaler to be placed in a bowl of hot water.

On June 26th, a consultation was held with Dr. Henry I. Bowditch, and, on examination, dullness, moist rales and bronchial breathing were noticed above and below the right clavicle, the rales being not quite so numerous as before. Temperature and pulse were normal. The patient was able to eat more, felt stronger and coughed less. The sputa were unimulated, green-

ish, and once or twice during the week had had a reddish tinge.

June 27th. Sputa examined by Dr. W. W. Gannett, who reported that *the specimen contained numerous bacilli*.

June 30th. Examination showed that the signs were certainly less marked but still distinct in the right apex and the patient reported, "No headache for two weeks." I prescribed, as a residence for the summer, Bethlehem, N. H., having refused to allow the family to go to the seashore as proposed, and ordered the same medicines to be continued, with instructions that the patient should be in the open air every moment possible during the day, to be back by sunset at the hotel and never to remain outside the house after eight p.m.; to take no long fatiguing excursions and to eat all the nourishing food possible.

One month later, the mother of the patient wrote that her daughter's health had steadily improved from the first day of their arrival, and that she was beginning to take active exercise without the slightest fatigue. The patient, however, complained of a slight pain in the right side near the axilla. The cough had nearly disappeared; the menses had appeared within a day or two of the normal time, and improvement was so marked that all medication except painting the chest with iodine had been discontinued. I recommended a simple liniment to be rubbed on the chest over the seat of pain, and ordered the Hypophosphites to be continued.

Three months later the mother again wrote enthusiastically of her daughter's gain. The patient had gained seven pounds in six weeks, played lawn tennis and took long walks without the slightest fatigue, slept all night like a child, and only had a slight "hemming" through the day. The record of the morning and evening temperature for five days at this time showed it to be normal; the pain in the chest had ceased and the patient looked "the picture of health."

In spite of the continued favorable reports, I was skeptical as to the permanent restoration of health, and thought it to be probably but a temporary gain to be followed soon by a renewal of the symptoms.

About the middle of September, after a stay of two and a half months in Bethlehem, the family returned to Boston for a few days en route for Texas, a part of the country I should not have selected as a winter resort, but which for various urgent reasons seemed the best place for the patient, whom I would not allow to remain in Boston for the winter.

Upon examination, the general appearance was of excellent health, the patient being much stouter than in the early summer.

A slight huskiness of the voice was noticeable, however, and an occasional clearing of the throat and slight cough after laughing were enough to strengthen my suspicions that there was still trouble left. No sputa could be obtained at any time for examination. The patient complained of occasional slight "stitches" in the chest, but no localized pain, and felt perfectly well.

Physical examination showed dullness still present in the right apex. Rales of a finer, drier quality, and much fewer in number than before, were heard in this region and the coarser rales had disappeared. The expiratory murmur was marked, with slight bronchophony. Respiration in the left apex normal. Pulse 68, temperature 97.8. During the stay of a few days

in Boston, as the patient's appetite failed and the slight cough increased. I hastened her departure as much as possible.

For the next eight months, which were spent in various parts of Texas, I continued to receive enthusiastic accounts of the daughter's health from both parents, with one exception, when, having been subjected late in the winter to very heavy fogs in Galveston, the patient complained of a great sense of oppression in the chest, and of general debility, symptoms which speedily disappeared upon her going to San Antonio, where she remained until the following spring, the early part of the winter having been spent in the interior of the State, where, in spite of great household discomforts and exposure to the blasts of the so-called "Northerners," icy winds, which suddenly rush over that region in winter, she remained perfectly well, while other members of her family suffered with severe colds and coughs. A slight clearing of the throat was occasionally noticed, but so slight that her mother remarked that had it not been for the previous summer's experience, a second thought would never have been given it and was no more than had been present at times ever since childhood, and the patient weighed more than ever in her life before, namely, one hundred and fifty-five pounds.

On May 19, 1884, nearly one year after my first examination, the patient returned by sea to New York and thence to Boston, where she arrived with a heavy cold taken in New York during a violent rain storm. Headache, with a return of slight pain occasionally noticed in the upper right chest, were also present, but in a few days all these symptoms disappeared.

Examination showed upon inspection a slight hollow under the right clavicle. Dulness noticed as before. The respiratory murmur was less pure than on the left, but it was almost impossible to get any definite râle, even after cough, but occasionally an indistinct "click" could be heard. Voice rather nearer than on left. Temperature 99.

The patient remained in Boston until the last of June and then went at my recommendation to spend the summer near Lake Champlain and in the Adirondack region, a spot which had seemed to me peculiarly suited for such a case. Here she remained by my advice, in spite of the adverse criticism of many of her friends, who insisted upon her absolute health, until the following spring, and then returned to Boston the picture of robust health, and declaring that, with the exception of an occasional neuralgic headache, she felt absolutely well; that the pains in the chest had disappeared, that long walks and rough climbing caused no shortness of breath, but merely a healthy fatigue, in short, giving a description of as perfect health as one could desire. All medication had been given up several months before.

Examination of the chest showed a return to its normal contour, the hollow under the right clavicle having disappeared. The percussion note revealed little difference between the two sides, although at the upper right there was still very slight dullness and a feeling of inelasticity was marked. The respiratory murmur in this region was rather harsh, and after a slight cough under the right clavicle a faint "crackle" was occasionally heard, but the moist coarse râles heard in the examination of two years before, had entirely disappeared, while the "nearness of voice" at the upper right, was not quite so marked as before.

Considering it wiser for the moral effect upon the patient that she should be told, at the end of my examination, of her recovery, and thus be relieved from the depressing effect of a constant watch upon her symptoms, I bade her, although recognizing in my own mind the possibility of a renewal of the morbid process in the future, to forget that she had ever needed a physician, merely cautioning her against foolishly exposing herself in any way in the future. Up to the present time I have had no reason to think my advice unwise, and in my occasional interviews with the patient during the past few months, I have watched in vain for any symptom, apart from those to be noticed only in a physical examination, which to the medical eye and ear would suggest anything other than a condition of perfect health.

We have, then, the history of a young lady, previously strong and well, seized with sudden and alarming symptoms of acute tubercular disease in the apex of one lung, followed in a few months by a cessation or "drying up," as it were, of the morbid process and consequent shrinking of the lung substance in the affected region, and, so far as outward appearance are concerned, a complete renewal of the patient's health.

What have we to learn from this case?

Two facts of marked importance, it seems to me: first, that the rapidity of the fatal result in phthisical cases is not *always*, as thought by some, in direct ratio to the number of bacilli found in the sputa, (that is, the greater the number of bacilli, the more rapid the course of the disease,) and second, that the presence of even numerous bacilli in phthisical sputa is not inconsistent with complete arrest of the morbid process and subsequent renewal of the patient's health.

One case like the above, as proof of these assertions, is, of course, of great value to us in making our prognosis, in similar instances when, following the teachings of those whose opinions we respect, we are led to give the gravest prognosis and feel no hope for the recovery of our patient whose sputa reveal the presence of the bacillus tuberculosis.

In an article entitled "The Pathological and Practical Relations of the Doctrine of the Bacillus Tuberculosis," printed in the *Philadelphia Medical News* of January 19, 1884, Prof. Austin Flint writes, "So far as my experience goes, an abundance of bacilli in the sputa of phthisical patients is evidence of active progress of the disease, and vice versa," and in a conversation with him last spring, he stated that although unable to say absolutely that he had ever so expressed himself in writing, his decided impression was that the presence of bacilli in large quantities in phthisical sputa was a sign of a rapidly fatal termination of the disease, an opinion which, coming from such a source, we are bound to respect and make the case in question of still greater importance.

I have used the term "complete arrest of the disease," rather than the word "recovery," in this case to satisfy those who with justice claim that we have no right to use the latter term unless the part affected shall have resumed its normal condition. The use of the former term, however, is justifiable, inasmuch as it does not preclude the possibility of a renewal of the trouble at some future time.

— The President has appointed Andrew H. Ward to be special examiner of drugs, medicines and chemicals in the district of Boston and Charlestown.

THE INOCULATION, PROPAGATION AND PRESERVATION OF THE VIRUS OF ANIMAL VACCINE, WITH A DESCRIPTION OF THE APPEARANCES OF KINE POX, AND DEMONSTRATION OF THE VACCINE VESICLE UPON HEIFERS.<sup>1</sup>

BY S. C. MARTIN, M.D., OF BOSTON.

WHEN, in response to an invitation by your secretary, gentlemen, received a short time since, I promised to address this society upon the subject of animal vaccination, I had in contemplation merely the preparation and reading of a paper upon that subject. Afterwards, however, at his earnest solicitation, and because, on reflection, I appreciated that it would serve to usefully supplement and illustrate my remarks, I decided to present for your inspection to-night an animal at present undergoing the disease. I trust that the opportunity I am thus able to afford you of observing the appearance of cow-pox, as artificially produced, will be productive of sufficient interest to you, to warrant the very considerable trouble and inconvenience which this has necessarily caused me. I will allude to this animal later on.

I do not propose to treat you to any extended remarks in regard to the comparison of vaccinia produced by heifer-transmitted virus, and that from the human subject after many years transmission from arm to arm, that is, humanized virus. This subject has been fully and convincingly presented to the profession by my late father, in his Report on Animal Vaccination, made to the American Medical Association in 1877, and published in the transactions of that year; and abroad by Bonsquet, Steinbremer, Estlin, and a host of others. Those of you who were in practice fifteen years ago, and tried the experiment which my father urged upon all, of vaccinating a child upon one arm with the old humanized virus, and upon the other with the cow-pox of Beaugency, and watched the progress of the vesicles on the two arms throughout their entire course, certainly do not need to have the differences described. It is no longer possible here to observe the effects of long-humanized virus. There is probably now none of it in the country; that which passes under that name being but a few human removes from the cow. Which of the two forms of the disease would *a priori* appear, and has shown itself to be, the better protection against small-pox, is to my mind, a matter upon which there is no room for difference of opinion. I have here for your inspection the very interesting plates of Bonsquet and Decanteleu, illustrating most clearly the differences in the action of the long-humanized and original cow-pox virus.

Before entering upon the more practical part of my remarks, it is important to define just what true animal vaccination is. I know of no better definition than that by my father: "The inoculation of a young selected animal of the bovine species, from an original spontaneous case of cow-pox, from this others, and so on, in continuous and endless series, as the source and the only source of virus for the protection of the human race against variolous disease." This alone is true animal vaccination. Retro-vaccination, or the inoculation of animals with humanized virus, is an entirely different matter and has nothing to recommend it.

A few words in regard to some of the various stocks of cow-pox. On March 28, 1866, the famous case at Beaugency, France, was discovered. From virus derived from inoculation from this, Professor Depaul continued the propagation of animal virus at Paris, under the auspices of the Academy of Medicine. This was the stock introduced into this country by my father in 1870. Various other cases of spontaneous cow-pox have been discovered from time to time in Europe, with virus from which animal vaccination has been and is still carried on in a number of establishments, notably at Brussels, Amsterdam, Rotterdam and the Hague.

After the first experimental inoculation of two calves, animal vaccination was not carried on at Beaugency, but was immediately transferred to Paris, and to that city the practice of the method in France was confined. A knowledge of this fact may, perhaps, in the future prevent a repetition of the ludicrous mistakes which we occasionally see in print, that various individuals have from time to time imported animal virus into this country from Beaugency.

When in Paris in 1873, my father was assured by Professor Depaul that the Beaugency virus, sent to him in 1870, was the last which left the city before the siege in that year, and that during the siege, the "stock" was lost. The animal virus employed since the Franco-Prussian war, is from other stocks, discovered since that of Beaugency.

In February, 1881, a case of suspected cow-pox was reported to this society by Dr. E. W. Cushing, and was immediately referred to my father, who accompanied Dr. Cushing to his brother's farm at Cohasset. He there found several cows suffering from an eruption on their teats and udders. With virus from these, my father and myself inoculated several animals as well as children, obtaining undoubted typical vaccinal effect. This stock I have continued uninterruptedly since, and, as far as I know, it is the only authentic case of cow-pox in this country which has been preserved.

I keep up three different stocks continuously, namely, the Beaugency, Cohasset, and the Esneux stock imported from Dr. Warlomont of Brussels; reserving the upper flank of the animal for the Cohasset, the lower flank for the Belgian, and the belly for the Beaugency, thus keeping the three stocks entirely distinct, and issuing the virus from all indifferently. They appear to be all equally typical in appearance and results.

It goes without saying that the animal to be vaccinated should be in perfect health and condition. This must be preserved by proper sanitary measures not necessary to detail here. The animals should be from six to eighteen months old. Too young animals are troublesome to care for and manage, and those too old and large are not only difficult to control, but, notably in the case of those which have borne calves, are probably not free from danger of tuberculosis. I use bulls and heifers indifferently. The animal is secured upon the operating table in the same manner as the one now before you. Portions of the flanks and belly are cleanly shaved, as you observe. Scarifications are then made in precisely the same manner as in the human subject, not deep, but merely sufficient to produce a slight appearance of serum tinged with blood. These I make some three-quarters of an inch by half an inch in size, and place them at intervals of at least

<sup>1</sup> Read before the Section for Clinical Medicine, Pathology and Hygiene of the Suffolk District Medical Society, November 11, 1885.

an inch and a half apart. The fluid virus taken directly from an animal, in which the disease has matured and lying upon an adjoining table, is then thoroughly rubbed into these scarifications. The disease matures at about the seventh day. In this, however, experience and careful inspection of the vesicles is necessary to determine the precise time, it depending somewhat on the condition of the animal and climatic influences. During the progress of the disease, the animal is but little affected, the temperature rarely rising more than two or three degrees. Occasionally in a very fine development of the disease, the animal may lose its appetite for a day or two.

The vesicle on being opened, is wiped clean of any blood or pus, and gentle pressure is then applied. The fluid contained in the vesicle is of a light amber color, and should have an unctuous, smooth character. In animals where the disease is accompanied by excessive action, as shown by much tumefaction of the surrounding tissues, a large amount of thin, almost colorless fluid is poured out, due to an admixture of an excessive flow of serum with the virus itself. I shall allude to this matter more at length in a moment. In some calves, from the finest vesicles it is impossible to obtain lymph without a certain tinge of color, due to the admixture of a minute quantity of blood. This, it can be readily seen, is not of the slightest importance in virus taken from the animal. It was always my father's custom, and is my own, to use those points most tinged, not only for vaccinating other animals, but also for human vaccinations. The sharp end of the ivory points is charged on both sides with the fluid virus as it exudes from the vesicle. When dried, the points are wrapped in cotton in packages of convenient size, then in paper, and finally, are hermetically sealed in gutta-percha tissue.

This effectually guards against moisture, and if care is taken to keep them cool as well, they will retain their efficacy for a considerable time. I have myself made vaccinations with points so kept for over a year, and have obtained perfectly good and typical results. This, however, is not recommended. Points should be ordered only in small quantities as required, and used within a few days or weeks. In this, and also in all the details of propagation, it is not what may perhaps suffice, but what experience has shown is safe and good beyond peradventure.

As to the form of virus, I recommend nothing but fluid lymph dried upon ivory points, prepared as above described. Crusts are liable to prove inert, and, unless used with the greatest care, may cause very bad results from partial decomposition ensuing after the crust has been moistened. They are apt also to encourage highly undesirable methods, such as inserting the dry, pulverized crust, or portions of the crust itself into punctures; also mixing with water, and allowing the mixture to remain too long exposed to the air. This was one very serious objection to the "solid lymph cones," formerly sold in large quantities, but now it is believed, no longer in the market. These were composed of crusts and fragments of crusts, powdered, moistened, and molded into cone-shaped masses. They were not only open to all the objections applying to crusts, but the mode of their manufacture rendered them peculiarly liable to dangers evident to any intelligent physician. Storing fluid lymph in glass capillary tubes has been found very unsatisfactory. It was at one time much in vogue, but experience has shown that

virus so stored is extremely liable to prove inert, and unless sealed perfectly tightly, may become decomposed and dangerous. One great merit of points is, that it is well nigh impossible to have serious complications attending their use, if they are charged with pure, active lymph in the first instance. They either produce typical vaccinia, or, at the worst, prove inert owing to some accidental cause subsequent to charging. In distributing any form of virus, we must bear in mind that among so large a body of men as compose the medical profession, some will be found who will not use proper care on all occasions, and it is most important to issue only that form with which it is impossible to go wrong.

The propagation of animal virus, and its distribution to physicians, are at present, in several ways, in an unsatisfactory state. The *New York Medical Record*, in its issue of October 24th, 1885, editorially says: "At present in all large centres, bovine virus in vaccinating is mainly used, and the steadily increasing demand for this, has led to the formation of companies who undertake to cultivate and sell it, with a view primarily, to making money. These companies are not, as a rule, under any official supervision, and are at perfect liberty to disseminate worthless crusts or septic poison among the people. We learn, as an illustration, that, with a lot of bovine virus recently sent to Montreal, there were one hundred and two trials and one hundred and two failures, while other specimens have produced badly inflamed arms. Here, surely, is a most anomalous condition of things. It is apparent at once that the cultivation and selling of virus should always be under some official supervision. Most States indirectly compel the vaccination of children, and they should in all justice, see that this vaccination be made with pure and efficient material. But the public supervision of vaccine companies is not yet carried out as it should be, although it is a measure most imperatively needed for the security of the people."

The suggestion is most timely, and I hope it may some day be properly carried out. An attempt at an examination and report upon the various propagating establishments was made in 1882 by the National Board of Health, but was productive of no marked beneficial result. Some of the men detailed for the duty of examination were ludicrously incompetent, their reports showing on their face an ignorance of even the elements of the subject. The only efficient examination and report of which I have any knowledge, was made by the private enterprise of the *Medical News* of Philadelphia. Dr. W. M. Welch, of Philadelphia, the well-known writer and authority on small-pox and vaccination, was employed for the task, and the results were published in the numbers of the *Medical News* from April 15th to May 27th, inclusive, 1882.

Great commercial competition has arisen in the matter of supplying animal virus. The country is flooded with circulars, frequently illustrated with heads of heifers, and gentlemen in spectacles vaccinating calves, or adorned with fanciful mottoes, such as "National Standard" and the like. One ingenious propagator advertises that his virus was imported direct from the "vast herds of the Duke of Beaugency," doubtless a bucolic French noble, who, it is believed, thus appears in history for the first time.

Seriously, gentlemen, this does not show a promising condition of things. A regular physician, agent for the sale of vaccine virus, in a recent number of the

*Boston Medical and Surgical Journal*, after saying that he does not know whether the propagator for whom he is agent is a physician or not, but *does* know that he is a liberal business man, continues, "Animal vaccination and the supply of vaccine virus is a business or trade. There is no mystery about it, etc., etc." I trust, and am sure, that this is not the prevailing opinion among the profession. I desire most earnestly and emphatically to record my protest against such views. The advertising and puffing of vaccine virus, as too often carried on, is a "business or trade," and a pretty low one at that; but I insist and reiterate that the propagation of animal virus, worthy of the name, requires accurate professional knowledge, long experience, the utmost care, and I may add, *honesty*.

The distribution of virus to physicians is now largely done through druggists and instrument makers. My father and myself for several years refused to supply virus except directly to physicians, or through the hands of local agents in Boston for the convenience of the profession. We continued this rule until it became evident that physicians would not take the trouble to procure it direct, but preferred to rely on the nearest druggist. This is all wrong. Vaccine virus is not a substance to pass through three or four intermediate hands before reaching the physician. It is peculiarly liable to deterioration, and, furthermore, the physician should know just who propagates the virus he uses. I fear that in many cases, he is entirely in the dark as to this. Many propagators do not do business under their own names. Large numbers of "Companies" are advertising widely. Possibly, some of these are regularly incorporated companies and are conducted by competent men; but it is believed that some of them adopt the title merely as a convenient *nom de guerre*, like those of certain "Institutes" composed of a "Board of Physicians," in whose spacious laboratories skilled chemists and *sorcerers* compound precious elixirs for the relief of noble but erring youths. I wish to emphasize this matter somewhat for the reason that physicians have become far too careless as to the source of their vaccine supply. The druggist naturally will sell the virus on which he can make the most profit. Animal virus, properly and honestly propagated, is not cheap. By improper methods it can be produced in immense quantities. The temptation to do this, particularly in times of great demand, is irresistible to men who have no professional reputation to sustain, and who look upon the matter as a "business or trade."

Let me call attention to a case which has come to my notice. Dr. —, a reputable and competent propagator in the West, and whose virus had become identified with the name of the town where he lived had the following experience:—

A homoeopathic physician came to the town, assumed the name of the — Vaccine Co., and secured a powerful drug-house as his agents. He propagated no virus himself but gave to a number of ignorant farmers in the neighborhood, two cents a point for charging the points with some sort of fluid, which they managed to get from their calves. It being in a time of great demand, these points were sold in great quantities by his agents, as virus from the town named. They naturally produced far from satisfactory results, and much of the blame fell upon Dr. —; physicians supposing it to be his virus. He exposed the fraud in the local paper. The selling agents of the "Company"

threatened him with a suit for heavy damages, but on investigation concluded to let the matter drop, and to close their connection with the "Company" in question.

The above is a good illustration of the propagation of virus as a "business or trade."

I have described and shown you what I consider the proper method of inoculating the animal and preparing the virus. My father and myself after many experiments, found it to be the best. The number of points which an animal vaccinated in this manner, will yield, is comparatively small; but I consider that any attempt to increase the yield is fraught with certain dangers. In times of great demand (the time above all when only what is *known* to be the best should be practiced) certain propagators have found this method far too old-fashioned and "unbusinesslike" for their views. An animal must be made to yield 15,000 to 20,000 points, or more. To accomplish this the following expedient has been adopted. A full-grown cow is usually selected on account of its size. Scarifications from two and one-half to three inches in length by some two to three inches in width are made on the flanks at intervals of about an inch apart. These produce large inflamed surfaces, often coalescing, so that at the end of seven days, one large sore will often occupy the whole scutcheon of the animal. Upon this being opened, an immense flow of *colorless* fluid results, with which points are charged. I state the method to you, and say frankly that I utterly disapprove of it. Such extensive scarifications with the great attendant inflammation, must necessarily produce an excessive flow of serum, and it would be a bold man indeed, who would confidently pronounce the resulting fluid free from the products of inflammation. It will readily be seen that such immense sores will yield an almost unlimited supply of this fluid. It seems to me that the practice is fraught with dangers, evident to any intelligent physician. Suppose the only possible trouble to be apprehended from such virus was either failure to produce typical vaccinia, or the production of vaccinia, *plus* a certain amount of inflammatory action, greater or less.

Surely, there being a better way, it should be practiced in preference, even if not so profitable, and even if it did not allow the propagator to be so "liberal" to agents and boards of health.

The wholesale propagation and distribution of improperly prepared virus, have done infinite harm to the reputation of animal vaccination. My father introduced the method as an improvement on the existing state of things. It is an improvement, and a great reform, if properly and honestly carried on; but many reports, a few of which I read to you, tend to show that from certain causes it is capable of becoming the very reverse of a reform.

The Board of Health of Louisiana writes, May 16, 1882:—

"Failure with bovine points during the present season has been the rule rather than the exception."

The Secretary of the State Board of Health of Arkansas writes, April 28, 1882:—

"The trouble in this State has been not so much from the bad effects derived from bovine virus, but rather, from obtaining no effects at all. Reports have reached me from all parts of the State in regard to the worthless character of much of the bovine virus employed."

The Secretary of the Medical Association of Alabama, writes, April 30, 1882:—

"To sum up the whole in brief, the profession here to a man, prefer humanized virus to the bovine lymph in any form, and have long since abandoned it."

The State Board of Health of Minnesota, writes, April 28, 1882:—

"There has been much complaint in all directions."

Dr. E. L. Griffin, of Fond du Lac, Mich., an intelligent and able propagator of virus, writes, February 8, 1882:—

"I fully sympathize with your views on what is being done during the boom to supply the demand, and greatly fear that annual vaccination will get a bad set-back from the experience of this season."

The same gentleman writes, March 6, 1882:—

"Those infernal 'cones' have done infinite mischief, I believe, in the West. The other day I got a sharp letter from the Secretary of the Board of Health of a neighboring city, upbraiding me on the quality of my virus, saying that it did not give typical developments of pock, but produced enormous sloughs and sore arms, etc., and wished to know what I was going to do about it. Upon inquiry by correspondence, I found that they had been using cones, obtained from a druggist in Chicago, and that the stuff was represented as coming from me."

Dr. D. A. McLean, of Stanton, Mich., writes, May 8, 1882, in regard to his experience with points from the notable vaccine company before referred to, whose virus was propagated by farmers. This virus he procured through a druggist, supposing it to be that propagated by the gentleman who exposed the fraud, as narrated before. Dr. McLean writes:—

"The remaining 1,400 cases were vaccinated with points obtained from that institution. A large proportion of these cases were very severe, the fever high and very frequently confining them to the house for a week or more. The local manifestations were great swelling, redness, pain, in fact all the symptoms of vaccinia greatly intensified, and frequently resulting in a deep, foul, and very offensive ulcer. These were very slow to heal; in fact, at this date, nearly three months after the vaccination, I am told that some are not healed. In a large number of cases, I am satisfied that no true vaccine pustule was formed, merely a septic sore, and these were the worst cases to heal, and the constitutional disturbances were the greatest. From my experience I am led to believe that the virus was not pure, that is, proper care had not been used in propagating and preparing it; that pus from ordinary suppurating sores had been used to charge the points, or at least, had become mixed with the vaccine virus."

Dr. Benj. McCluer, of Dubuque, Iowa, writes, July 7, 1882:—

"I used one 'cone' during my vaccinations last December and January. I became fearful of them, as also of the points. The vaccinations were so severe in development, such immense ulcerations occurred in apparently healthy children, that I became doubtful in regard to the propriety of vaccination at all. In fact I lost all confidence in the integrity of the parties dealing in vaccine matter, and felt that they were actually trifling with the health and lives of the community, as well as the character and honor of the profession which was procuring the supply of vaccine matter from them. I do hope that some way may be devel-

oped by which in the future the profession may be able to secure pure vaccine."

Dr. John B. Weston, of Chester, Pa., writes, October 6, 1882:—

"Part of the time I used a cone which came in a metal box with a file. Part of the time I used a crust. My experience with the cone was vexations in the extreme. Erysipelas was not infrequent, and I am afraid that the fever and disturbance in one case, if not in two, caused a child's death. The sores in most cases were horrible, and many told me that they would rather have variola itself than what they had gone through. It was not due to any carelessness on my part, for I did not use any a second time, or mix one day's filings with another, so I know the fault was not mine."

Dr. T. S. Hopkins, of Thomasville, Ga., writes to the *National Board of Health Bulletin* of March 4, 1882, describing the effects of vaccination with virus in the form of "cones":—

"The result has been fearful. Nearly every one vaccinated has suffered severely from erythema, or erysipelas, the arm swollen from shoulder to wrist, and the point of puncture presenting the appearance of a sloughing ulcer discharging freely sanious pus. Many of the cases have been confined to bed with high fever from five to ten days, requiring the constant application of poultices, and the free use of morphia for the relief of pain. It (the virus) 'takes' in all cases, regardless of previous vaccination as shown by well-pitted mark, and the inflammation begins frequently on the second day. Those who have tried it tell me they would much prefer to have small-pox."

I have reports of many more similar groups of cases, but will not prolong my quotations to a tedious length. The above are merely selected as being well-marked instances, showing clearly the symptoms of septic poisoning in a greater or less degree. It will be observed that the above are groups of cases, showing precisely similar symptoms in a large proportion of the persons vaccinated.

Single isolated cases of even severe complications, the result of accident, or in unsound or sickly subjects, prove nothing; but such instances as given above are unmistakable.

The vaccinia, induced by heiter transmitted virus, is characterized by a certain intensity of action which might be startling to one accustomed to seeing only the effects of the enfeebled virus of long humanization; but this intensity is not to be deplored, and is only what is necessary for proper protection against variola. It should run a regular course, the vesicle should not break down except through exposure to violence, and, finally, the crust should fall, leaving a healthy, thoroughly healed cicatrix.

In speaking of these various abuses, being a propagator of vaccine virus, I am placed in a somewhat delicate position, and one in which my motives may be easily misunderstood and wilfully misrepresented; but I should be remiss in my duty if I did not present to your notice, as forcibly as I can, the matter of all others connected with my subject, which has to-day become of the most vital practical importance to the profession.

My father having introduced the method into this country, and having advocated it through good and evil report, stands in relation to it very much (Waterhouse, in earlier days, did to vaccination. Any

failure or complications attending it are indirectly laid to his charge.

The complications spoken of above, as well as the woful lack of success, are not due to the *practice*, but to the *malpractice* of animal vaccination. With animal virus properly and honestly propagated, the chances of failure or serious complications are exceedingly small.

Practically the only guarantee which the physician has that the substance on the end of an ivory point is pure virus, or indeed, that it is vaccine virus at all, is the reputation, skill and honesty of the propagator. So long as physicians and boards of health will buy, and recommend virus simply because it is cheap and produces a "sore arm," utterly regardless of the source of supply, or whether the propagator is a physician or not, so long may we expect a reckless increase in production, the keenest and most dishonest competition, and such results as I have shown above.

Animal vaccination is too efficient a safeguard against a loathsome disease, to have its good name injured by ignorance or knavery. The remedy is in the hands of physicians. They should inform themselves of the source of supply of the virus they use, and if abuses arise, should denounce them fearlessly, and not leave the disagreeable task to persons, whose pecuniary interest in the matter, renders their motives liable to misconception and wilful misrepresentation.

## Reports of Societies.

### MASSACHUSETTS MEDICAL SOCIETY, SUFFOLK DISTRICT. SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE.

ALBURN N. BLOOMFIELD, M.D., SECRETARY.

NOVEMBER 14th, 1885. Meeting called to order at 8 o'clock, Dr. F. I. KNIGHT in the Chair. The records of the last meeting were read in summary and approved. There being no incidental business, the Chairman announced the first paper by Dr. S. C. MARTIN, of Roxbury, entitled

#### THE INOCULATION, PROPAGATION, AND PRESERVATION OF THE VIRUS OF ANIMAL VACCINE, WITH A DESCRIPTION OF THE APPEARANCES OF KINEPSON, AND DEMONSTRATION OF THE VACCINE VESICLE UPON HUIFERS.<sup>1</sup>

The essay was attentively listened to by a very large audience, who warmly applauded the various recommendations for securing the purity of the vaccine supply, and for a proper professional and financial system of conducting the business element connected with the propagation of vaccine virus. Upon a large and heavy oaken table in front of the audience was a large heifer about eighteen months old, and weighing about six hundred pounds. The animal had been inoculated some days previously with three separate and distinct stocks or varieties of vaccine derived from three independent and widely separated sources. In the discovery of the vaccine disease in so-called "spontaneous" development in a single animal at each place. The heifer had been inoculated at about twenty-five separate points, and presented a large

number of well-formed vesicles, from which lymph was taken and ivory points were charged as is ordinarily done for the commercial supply.

The discussion was opened by Dr. S. W. ABBOTT, of Wakefield, Chairman of the Massachusetts State Board of Health, who stated that he had been interested in the subject of vaccination as a protection from small-pox for many years. During the late Civil War, the source of the virus obtained for the army was from retrovaccination from the human species to the bovine, and from this source many thousands of soldiers acquired immunity from small-pox. Dr. Abbott entirely agrees with Dr. Martin in the necessity of the greatest care to preserve the purity of the bovine virus, and in the importance to the medical profession and to the entire people that the business of propagating vaccine virus should be entrusted only to such persons as are well known, responsible, and honest; besides possessing the necessary medical knowledge required for the safe and scrupulous management of so delicate a pathological process as is that of the vaccine disease in cattle.

The virus of vaccine is subject to many dangers even when most carefully produced and most thoroughly protected. From the moment the lymph leaves the parent vesicle in which it was formed, it is undergoing a process of constant deterioration. Under some conditions, the best virus may become quite useless as a protection against the ravages of small-pox. I have known this to be the case in many parts of the United States, and to some persons, it has been the cause of a loss of confidence in the utility of vaccination as a prophylactic measure. Dr. Griffin, who is one of the pioneers of vaccination in the West, has observed the same failure in regard to protective power in the virus, which he traces to the following causes: *First*, the great distance from the source of the virus, which necessarily exposes this delicate material to many undesirable changes of temperature, and to a longer period of time between its production and the time of its use for protective inoculation. All virus is exceedingly perishable, and is constantly suffering from the moment it leaves the heifer. There is no doubt that ivory points are much to be preferred for the preservation of the virus, as they are smooth, shapely and convenient, and are, beyond question, the most useful carrier ever employed.

The use of crusts resulting from vaccine vesicles, or any portion of the dried scab, should be utterly abolished, and these substances should be entirely discarded in the protective and prophylactic treatment of variolous diseases. Many accidents have occurred from their use for purposes of vaccination, and not a few unfortunate complications, such as erysipelas, abscess, sloughing of the skin of the arm, and occasionally, septicaemia and death, have followed the introduction of the scab, or crust, or the so-called "cones," or parts of these substances into the human system. Of all these materials for inoculation, the "cones," which were formerly more extensively employed than now, are undoubtedly the most dangerous, as they were manufactured from scabs, crusts, and other products of the vaccine process, together with the frequent admixture of manure and other forms of filth and decomposition.

The proper time for preserving the virus for inoculation is at a period before the crust is formed. After this time, the contents of the vesicle become purulent,

<sup>1</sup> Published page 566 of the Journal.

and the resulting scab or crust is formed, in part at least, of the dried and changed pus of the later stages of the vaccine sore. When a scab is used, the pus is introduced into the system. The results of infection of the system with the products of septic suppuration are too well known and of too grave a character to warrant the employment of a method involving the needless exposure of human beings to the unnecessary perils of so grave and unscientific a procedure under the guise of hygienic protection from a loathsome infective disorder.

The use of capillary glass tubes containing lymph is also to be discouraged, as the fluid contents are very easily decomposed and may be already in a putrid condition when employed for vaccination. The tubes may also contain many foreign germs, which certainly contaminate the virus and may entirely pervert its usefulness. The content of the tubes is also often diluted with glycerine or some other fluid, sometimes, no doubt, as a means of preserving the virus, but frequently, also, it is to be feared for purposes of fraud in "extending" the virus. Dr. Abbott spoke of the inaccuracy of terms designating variola in the cow as a "spontaneous" disease. When we ask ourselves, "what is a 'spontaneous' disease?" it seems hardly logical to include among such diseases one so highly infectious, so thoroughly marked and so definitely limited as is cowpox. Is it, indeed, possible that an infectious disease can arise spontaneously?

Dr. Abbott states that he has seen no less than twenty cases of cowpox among the cattle belonging to farmers in this Commonwealth. True vaccination will not "take" on animals which have had this disease during at least two years. Those milking such diseased cows will frequently acquire the disease upon the hand, from contact with the cow's udder. One cow has often proved a source of infection for others of the same herd, by transmission of virus from one to another by means of the hands of the milkers. This has been successfully prevented by the simple precaution of milking the diseased animal after the others.

Such cases among domestic cattle have been observed in Lexington, Woburn, Saugus, and some other towns, and were considered both by the farmers and the State Board of Health to be undoubted cases of cowpox.

The production of animal virus is accompanied by much sacrifice of time and money, and much disappointment and vexation, owing to the spasmodic character of the demand for it as a protection against variola. During the times of epidemic small-pox, the demand for virus is very large, while in time of absence of the disease, the demand for virus is almost nil. It is therefore highly important that the production of vaccine virus should be in the hands of trustworthy and responsible men, in order to insure the integrity of its propagation in time of peace, as well as the integrity of quality in periods of epidemic small-pox.

The medical profession of the United States should recognize the laudable efforts of Dr. Martin to sustain and propagate pure and efficient virus, and support him in his beneficent work as they supported his father before him.

Vaccination can be made thorough and protective only by observing accurate methods in its employment. One of the chief disappointments in vaccination is due to the advanced age and consequent deterioration of the virus employed. A complaint was recently made by a physician in a distant part of the State, that the vac-

cine obtained for use in that town was quite worthless; and produced no appreciable result in any case. Investigation revealed the fact that the physician derived his vaccine from the local druggist, who had obtained a supply some time before from a wholesale drug store in Boston. In this case the virus had passed through several hands before it reached the physician, and much time had elapsed between the charging of the points from the lifter and the vaccination for protection from variola. It would be desirable if all packages were dated, so the physician might be sure that the virus was of recent production. Otherwise the whole process of inoculation as a protection from small-pox might be justly described in the words of a distinguished French physician who said, "Vaccination is a deceptive operation performed with hypothetical virus."

It may be added, that if due attention were given to the source from which the virus is obtained, and proper care is exercised in the operation of vaccination, there would probably be much less, or none at all, of the excited sentiment and frequently also open opposition to preventive inoculation for small-pox; and anti-vaccination riots would be no longer known.

Dr. J. H. McCollum, City Physician of Boston, stated that he entirely agreed with Dr. Abbott in the importance of employing only the virus procured from well known and honorable sources, as we otherwise have no guarantee of its power as a protective, or of its freedom from foreign and dangerous contamination. Dr. McCollum has used virus procured from Dr. Martin as well as that coming from other sources. He has occasionally seen the virus produce very sore arms but has never observed bad results. He now unqualifiedly recommends bovine virus. Human virus was formerly very generally employed, and this too without any bad results, but the protective power of humanized virus is infinitely less than that of bovine virus. One of the greatest curiosities in vaccination is the influence of the vaccine disease upon true variola. This was recently illustrated in the case of a man who was exposed to small-pox, and two days later was vaccinated with cowpox. The eruption of variola appeared, as did also the vesicles in the vaccination. The two diseases progressed, but the vesicles of small-pox never became pustular. The entire disease was checked at the vesicular stage.

The importance of vaccination after exposure to small-pox is therefore even greater, if possible, than before exposure to that disease. The virus obtained from the inoculation of post-exposure is preferable to that from cows, owing to its freedom of the latter to tuberculous disease. In the post-exposure studies in tuberculous subjects, important results would be possible of infecting the human body with the virus of this disease.

Dr. S. L. Auer, who has had twenty years' experience of the present vaccination of the population with bovine virus is followed by Dr. H. C. Reed. In many cases the results are of a different character. It is possible that the virus obtained at this time provokes a more rapid and more extensive reaction after vaccination.

Dr. Martin is of the opinion that the virus is characterized by a certain type of reaction more than is observed from human virus. In the mild disease which runs its course in a few days, we observe a well-marked disease which may extend to twenty-one

to thirty-two days. The arcola appears at the ninth to tenth day, and the fever also appears at that time. The process affects the entire thickness of the skin and not simply the epidermis. The intensity of the reaction is a valuable indication of the protective power of the virus. Indeed the earlier observers of this process judged the success of the inoculation from the degree of fever produced. The bovine virus induces a distinct disease which protects the system from an invasion by small-pox, which humanized virus does not. The arms of servants and laborers are more sore on account of their occupation which necessitates exposure of the limbs to various injuries as well as to sudden change of temperature, both of which doubtless cause increased severity in the vaccine disease. The term "spontaneous" cow-pox is certainly a misnomer. It is used simply as a convenient expression in cases where the source of infection of the cow cannot be traced. "Spontaneous" infective disease is doubtless derived from some tangible source, but it is impossible to discover its origin. If Dr. Abbott has seen so large a number of cases of genuine cow-pox, he has certainly been far luckier than Dr. Martin. There may be isolated cases, but they are certainly not generally known. The only indisputable case now recognized as occurring in this country is the Cohasset case which has since been propagated by Dr. Martin in uninterrupted succession. There are many known cases of spurious disease which make the hands of the milkers sore. Such cases have long been observed, and were reported by so old an authority as Edward Jenner himself, but this disease is not cow-pox, nor has it any similarity to the true disease in the way of protection against small-pox.

The Section then repaired to the small hall, where Dr. E. W. Cushing exhibited a series of microscopic preparations showing the Bacillus of Tuberculosis and that of Anthrax (Malignant Pustule).

Dr. CUSHING then read a paper on

#### THE SPECIFIC AND INFECTIOUS CHARACTER OF TUBERCULOSIS.<sup>2</sup>

which was followed by a paper by Dr. VINCENT Y. BOWDITCH upon

#### A CASE OF PHthisIS WITH BACILLI. COMPLETE ARREST OF THE DISEASE.<sup>3</sup>

The discussion of both papers was opened by Dr. Henry I. Bowditch, who stated that practically he had for many years considered consumption to be a contagious disease under certain conditions. He always advises husband and wife to sleep in separate beds, and he much prefers them to occupy different rooms. There is no longer a reasonable doubt that the bacillary organisms found associated with tuberculosis have the power to produce that disease. The many and careful series of experiments so extensively performed and reported in Europe, are convincing upon this point. The main question now seems to be this: "What influence is the presence of bacillary organisms to exert upon our opinions in diagnosis and in prognosis?" Where do we stand in relation to these bodies in the actual treatment of tuberculous diseases? When the bacillus was first discovered in connection with tuberculosis we were inclined to look upon its presence as a sign of the gravest significance. These first opin-

ions are at present undergoing a modification as we observe cases in which the undeniable presence of the bacillus is not necessarily followed by a fatal course of the disease.

The case reported at this time, as well as others recently published, show that we need not feel entirely discouraged when bacilli are present, and conversely, we should not be so highly encouraged when they are absent. We do not yet know the absolute value or the entire relation of the bacillary organisms to the course or termination of diseased conditions, nor their full bearing and influence upon diagnosis or prognosis.

Dr. KNIGHT said that he had seen a case in the early summer of 1884, in consultation with a practitioner of a neighboring city, in which the symptoms were quite acute, and in which the fears of rapid future progress were increased by finding numerous bacilli in the sputa. Contrary to expectation, however, the patient, who was a young lady, soon began to improve, and at last accounts had no cough, considered herself well, and had every appearance of being so.

Dr. Knight said that such cases in reality only confirm what we knew before, that is, that arrest may take place in pulmonary tuberculosis. Perhaps hitherto, in cases of arrest, we have been inclined to doubt the tuberculous nature of the disease. We can no longer feel this doubt.

Dr. CUSHING stated that the higher degree of infectiousness of tuberculosis among animals who were subjected to experiment was no doubt due in some measure to the fact that the healthy animals are frequently placed in pens which have been occupied by diseased animals; and that quite possibly the cages themselves may contain the germs of tuberculosis and thus render the animals confined therein more liable to tuberculosis. It is a very suggestive fact that in the experiments to determine the infectiousness of tubercle germs when suspended in vapor, the spray was conducted out of the building in which the laboratory was situated, to cages some feet away, and the windows and doors of the laboratory were kept carefully closed during the experiment. Every one of the animals thus exposed to the tuberculous spray became affected with general tuberculosis. This fact should be a sufficient indication for all possible care in averting contagion in the human tuberculosis. The disease is clearly to be classed not only as communicable, but as a highly infectious one.

Adjourned at 10.30 P.M.

#### NEW YORK COUNTY MEDICAL ASSOCIATION.

STATED MEETING, November 16th, 1885.

#### A DEMONSTRATION OF PHOTOGRAPHS OF PATHOLOGICAL SPECIMENS, TAKEN WHILE THE SPECIMENS WERE IMMersed IN WATER.

was made by Dr. J. M. GOLLEY. The specimens were of various diseased conditions of the bladder, penis, urethra, and prostate. For the purpose of being photographed they were carefully fastened upon black boards by means of pins and sunk in a tank of clear water, and the great advantage of immersing them in a fluid of the density of water was stated to be, that all the irregularities of the surface, instead of lying flat, were made to float. The result was extremely successful.

Dr. AUSTIN FLINT read a paper on

## ELEMENTS OF PROGNOSIS IN BRIGHT'S DISEASE.

Having alluded to the prevalent notion that the fact of an individual having Bright's disease was equivalent to a sentence of death by a legal tribunal, he stated that there are a number of circumstances which might greatly modify a too unfavorable prognosis in many instances. Thus, the progress of the disease might perhaps be arrested entirely. Again, the disease might be progressive, but the progress made by it be so slow that the patient might continue comparatively free from danger; though some intercurrent affection, in consequence of the impaired condition of the kidneys, might prove fatal. Still further, the chronic disease might continue indefinitely in about the same state, and so, under favorable circumstances, not prove fatal.

The prognosis in Bright's disease was often of great importance to a patient as regards his business and family affairs, as well as his future health, and a number of points were to be borne in mind in the consideration of this subject. Acute diffuse, tubular or desquamative nephritis was not, as a rule, followed by the chronic form of the disease, or characterized by any renal lesion. The same facts were also true of sub-acute nephritis, such as follows scarlatina, for instance. It was to be remembered also that an acute, diffuse, tubular, or desquamative nephritis might be met with as an intercurrent disorder in the course of chronic Bright's disease. Under such circumstances a problem was presented which could not at once be definitely settled, since it was not certain whether the grave symptoms noted were connected with the chronic trouble, or whether they were significant of an acute attack of nephritis which would soon subside, and leave the patient in the same general conditions as before. When an acute attack of this kind did occur, however, it was very apt to leave the patient with a tendency to recurrent trouble of similar character.

In chronic Bright's disease the affection might remain latent for a long time. In order that the prognosis might be a comparatively favorable one, when it had declared itself, it was necessary that the kidneys should not be damaged beyond a certain point, and that the important organs of the body other than the kidneys should be capable of satisfactorily performing their functions. Also that the laws of health in general should be observed. If these conditions were maintained, even though the kidneys were damaged to the extent of one-half, the patient might continue to live in a fair state of health. Chronic Bright's disease might exist, without discomfort to the patient, for years, and then at length the pathological process in the kidneys involve the organs to such an extent, that they could no longer perform their functions; or, the accessory conditions might become sufficiently changed to give rise to serious trouble. Cardiac hypertrophy, it was to be noted, was frequently a result of this affection. But so long as the damage to the kidneys was limited, and the accessory conditions were favorable, the disease would produce little or no disturbance.

The object of treatment, then, was to prevent further progress of the disease in the kidneys, and to maintain favorable accessory conditions. In view of these facts, it could be readily seen how important it was to make an early diagnosis. The diagnosis made, the essential point was to see that a sufficient elimination of excrementitious products was carried on by the

kidneys. It was very easy to determine whether the elimination was sufficient or not by simply ascertaining the quantity of urine passed in the twenty-four hours, and testing the specific quantity with the urinometer. If it was found that there was renal adequacy the indication for diuretics, sudorifics, and hydrogogue cathartics was not present, and they would only do harm.

The diminution of excrementitious elimination was not a necessary indication of danger from uræmia, because vicarious elimination might take place, and tolerance thus be established. The prognosis of uræmic coma was naturally grave; but at the same time patients not infrequently recovered from it. It might possibly be due to an intercurrent acute attack of nephritis, or to the fact that tolerance was not established in the system. When there was pulmonary oedema and dyspnoea there was a chance of the patient's surviving; but if there were present what is known as renal asthma, which is not due to any condition of the lungs whatever, but in all probability, to the effect of a poison upon the nerve centres, Dr. Flint said he had found it invariably of fatal import.

In the discussion which followed the reading of the paper, Dr. George L. Peabody said that he could corroborate all the conclusions of Dr. Flint, and that he would like to emphasize, perhaps, even more strongly than he had done, the fact that chronic Bright's disease might continue indefinitely without causing serious troubles in individuals whose condition in life was such that no stress was brought to bear upon any particular organ by their mode of living. It had been his experience in quite a number of instances to find at *post-mortem* examinations an advanced stage of Bright's disease in cases when the presence of the affection had never been even suspected. In most of these it had no doubt existed for many years. He also appreciated the importance of looking at the manner in which the kidneys performed their functions. Another element in the prognosis was the situation in life in which the patient finds himself. If he could surround himself with all the care that was necessary, he had a chance of living for a number of years; while those who were exposed to bad hygienic conditions, hardships of diet, etc., would be likely to succumb in a comparatively short space of time.

DR. EDWARD G. JANESWAY thought, like Dr. Peabody, that for individuals in the poor condition of life, the prognosis of Bright's disease was of the gloomiest kind; but if the patient was so situated that he was able to go to warm climates in winter, and take every possible care of himself, he could probably live for a number of years in comfort. In many instances there was an intermittent element which had to be taken into consideration, albumen and casts remaining entirely absent from the urine for considerable periods at a time, and then returning again. He mentioned two cases now under his observation, in one of which the disease had already lasted for eleven years, and in the other for five years; but in both of them the most careful attention was constantly paid to every circumstance of the patient's condition, and any slight disturbance of the health corrected as promptly as possible. He had also one gentleman under observation who was told seventeen years ago that he had incurable Bright's disease. Personally, he had first seen him five years ago, when he had a second attack. The prospect then looked gloomy, but the patient had now to a great ex-

tent recovered from this second attack. While too dark a view might be taken of cases of Bright's disease, on the other hand, too favorable a prognosis should not be given. If no albumen or casts were found at the time of an examination, it was very important that the examination should be repeated. Rigidity of the arteries and hypertrophy of the left ventricle of the heart constituted grave elements in the prognosis.

Dr. E. M. MOORE, of Rochester, said that it was his belief that there were cases of albuminuria which go on for months, which do not get well and finally terminate in loss of life, and yet which at the end of a year, had not produced any change in the condition of the kidneys. He said there would be a great many such cases if they were less interfered with, and mentioned the instance of a young soldier during the late war who had had albuminuria for a number of months when he came under observation. He then took medicine every day for a year, during which time the albuminuria persisted. At the end of the year, however, this condition disappeared, and since that the patient had never had any trouble. He felt convinced in this instance, as in many others, that but for the persevering treatment, the kidney disorder would have progressed until the organs had become irremediably damaged and a fatal result would have ensued.

Dr. C. S. WOOD said that he agreed with Dr. Moore that cases occur in which albumen and casts are found for a long time in the urine, and then disappear, after which the patient goes on to live for years. He related the case of a gentleman sixty years of age, a captain in the United States Marine Corps, who, five years ago, was pronounced to have Bright's disease. After this, he had casts and albumen in his urine more or less constantly until two years ago, when he came under Dr. Wood's care. At that time, the specific gravity of the urine ranged from 1000 to 1004, and he was reduced in flesh. After treatment for a year, however, he had gained over forty pounds, and was now as well as ever. The albumen and casts had disappeared; the specific gravity of the urine was from 1010 to 1020, and he had every appearance of perfect health. In this case, it was but just to say that in early life the patient had been addicted to the use of intoxicating drinks, but that since he had begun to be troubled with albuminuria, he had given them up. The important point was, whether these cases past middle life ever recover. It was his own belief that this was the case more often than was generally supposed, and that more caution should be employed in giving an unfavorable prognosis before the patient's friends.

Dr. FLINT said that he had met with cases similar to those referred to by Drs. Moore and Wood, and the explanation of these, he thought, was this: In the cirrhotic or contracted kidney it was not uncommon for all the symptoms to disappear for a time, and they might disappear permanently. The kidneys had received a certain amount of damage; but if this did not exceed one-half of their extent, they could perform their functions sufficiently well under favorable conditions. Recovery might then take place in a certain sense, but the kidneys would always remain impaired, just as the lungs did after recovery in tuberculous.

Dr. T. R. VARICK, of Jersey City, said that in the prognosis it was of service to consider whether the trouble was simple and uncomplicated, or secondary to cardiac disease, poisoning by lead or other toxic agent, the excessive use of alcohol, or to some other patho-

logical factor. Then, the natural tendency and the method of termination of the disease ought to be taken into consideration. Some cases ended in apoplectic coma, some in pulmonary oedema, and others in heart-failure. All these various circumstances had an important bearing on the prognosis. In many instances, albuminuria was merely symptomatic of other conditions besides disease of the kidney, as, for instance, of the presence of a gravid uterus. It should not be forgotten that it is not a disease itself. Dr. Varick spoke of the intermittent character of albuminuria, and in this connection mentioned the following case: The patient suffered from asthma for a year, but there had never before been any suspicion of kidney trouble. Previously, he had had an attack of acute rheumatism, which left him with mitral insufficiency. The quantity of urine passed in the twenty-four hours was down to four ounces, and it was found that it was over one-half albumen. There was pulmonary oedema and anasarca of the lower extremities. Yet, notwithstanding this discouraging state of affairs, the patient improved under treatment, and was now very much better in every way. At times, there was a complete absence of albumen from the urine, and then again it would recur; the reason for which was, no doubt, the continuance of the cardiac trouble.

Dr. H. F. QUACKENBOS said that ten years ago, a patient of his contracted disease of the kidneys. In six weeks after the discovery of the trouble the condition became so alarming that he called in Professor Flint in consultation. The patient was confined to bed with the most extensive oedema, and looked like a piece of wax. Dr. Flint saw him four times and expressed his approval of the treatment which had been adopted. The trouble gradually subsided, the albumen disappearing from the urine within four weeks, and to-day the patient was entirely well. Dr. Quackenbos also related another somewhat similar case.

Dr. E. G. JANEWAY presented the spleen and small intestine of a patient who died of

#### TYPHOID FEVER FOLLOWING CHILD-BIRTH.

The woman was admitted to the hospital under the supposition that she was suffering from puerperal mania. She had been confined three weeks before admission, and fourteen hours after the birth of the child fever had set in, which continued up to the time of her death. It was learned that she had had an attack of malarial fever two months before confinement. The autopsy revealed the characteristic lesions of typhoid fever in the intestines and also marked pigmentation of the liver and spleen from the recent malarial trouble. During her stay in the hospital, the patient exhibited great irregularities in temperature, and she died on the twenty-first day from the commencement of the attack.

It might have been supposed that this was a case of typho-malarial trouble, but from the light thrown on it by the history and the autopsy, there could be little doubt that it was one of true typhoid. The history showed that the malarial poisoning, of which the marked pigmentation of the liver and spleen afforded plain evidence, had occurred two months before the beginning of the typhoid fever. In connection with the latter there was some bronchitis and broncho-pneumonia, as shown by the post-mortem. The six or seven lower patches in the small intestine were ulcerated out, and a few typhoid bacilli were also found in the intestinal tract. Dr. Janeway had met with two

other cases, (in one of which an autopsy was made and in the other not), in which typhoid fever, rather than puerperal sepsis followed confinement. The pigmented spleen, as exhibited, was of a dark chocolate hue, and greatly enlarged.

### Recent Literature.

*The Science and Art of Surgery.* By JOHN ERIC ERICHSEN, F.R.S., LL.D., F.R.C.S. Eighth edition. Revised and edited by Marcus Beck, M.S. and M.B., (London) F.R.C.S. Volume II. Philadelphia: Lea Bros. & Co. 1885.

That the character of this great work upon surgery is widely known and appreciated is shown by the appearance now of an eighth edition. No pains is spared to make it a success. The present volume alone contains nine hundred and eighty-four wood-cuts.

It is essentially an English system of surgery, and, as may be noticed in many English surgical books, the work of the surgeons of other nations is often overlooked and sometimes when mentioned is misunderstood and erroneously described.

The clumsy figure of Taylor's Spinal Support appears almost like a caricature of the extremely neat splint which Taylor uses and which is so efficient in his hands. We are told regarding it that it tends to separate the vertebrae when applied early in the disease, and that, therefore, in the first stages of caries, it is only a source of inconvenience, if not of positive danger. Such a misconception of its action contrasts strongly with the unqualified approval of Sayre's Plaster-Jacket, and one involuntarily wonders whether, in some of his visits abroad, Sayre may not have made more than a due impression upon the editorial mind of Mr. Beck. This conjecture gains probability when it is further found that the only extension splint for the hip, which is described, is the inefficient short splint of Sayre, while the valuable long splint used by Taylor is not even mentioned.

American Gynecology is also accorded but slight notice. The names of such men as Sims and Emmet are barely spoken of, and much of their most important work is not alluded to. Sims' Speculum is figured as a "duckbilled speculum."

The chapter on Lithotripsy contains mistakes and failures of comprehension which are even more inexcusable.

In describing the operation of Litholapaxy a figure of an instrument, which was laid aside by its author years ago, is introduced as illustrating Dr. Bigelow's present method of operating; while his last "Simplified Evacuator" is shown (Fig. 898), as "Sir Henry Thompson's Early Evacuator." This mistake is the more flagrant, as the figure has evidently been copied directly from Dr. Bigelow's published cut of his instrument. In view of the various attitudes of Sir Henry Thompson towards the American discovery, which he has finally adopted, it is somewhat amusing to find this wood-cut of Dr. Bigelow's Evacuator (that of 1882), which, Dr. Bigelow still thinks, cannot be altered for the better, entitled as if invented and rejected by Sir Henry Thompson.

The editor also falls into the error of supposing that Dr. Bigelow always uses large and heavy lithotrites. This mistake, which is a common one in England, seems to arise from the fact that for cases of large and

hard stones, he devised more powerful instruments than those previously in use—instruments much larger and heavier than he himself uses in ordinary cases.

These sins of omission and commission show a want of familiarity with American surgery, even in those branches in which American surgeons at the present time lead the world, and such mistakes occurring in a work in which our author undertakes to cover the whole field of surgery, furnish a strong argument for, in fact, show, the necessity of the modern plan of encyclopedic medical literature, in which each subject is placed in the hands of a writer who is an expert upon it.

*1. Text-Book of Medical Chemistry.* For Medical and Pharmaceutical Students and Practitioners. By ELIAS H. BARTLEY, M.D., Adjunct Professor of Chemistry in Long Island College Hospital, etc. With 40 Illustrations. Philadelphia: P. Blakiston, Son & Co. 1885.

This book is designed especially as a text-book for medical students, and has been prepared to fill a gap which undoubtedly exists between text-books which are too voluminous for the time at the disposal of the medical student and those which are too brief to be of any service to him. The author states that the book is largely a compilation, and he claims little originality in the subject matter it contains, but has used his own judgment in its selection and arrangement.

He has prepared, on the whole, a very satisfactory book. Part I. is devoted to chemical physics so far as is necessary for the proper understanding of the descriptive parts and to explain the theory and use of thermometers, spectroscopes, batteries, etc.; Part II. to theoretical chemistry; Part III. to the elements and their principal compounds, including their physiological and toxicological bearings; Part IV. to organic chemistry. An appendix contains some tables, together with analyses of the various fluids of the body.

Opinions differ so much as to the character of the instruction which a medical student should receive in chemistry, that it would be difficult probably to prepare a text-book on chemistry which would prove acceptable to even a majority of teachers of chemistry. We think, however, that this book is worth looking over by those who have thus far failed to find a satisfactory text-book, and we believe it will be found to meet the wants of a certain number.

*Fowne's Manual of Chemistry, Theoretical and Practical.* A new American from the Twelfth English Edition, embodying Watts' Physical and Inorganic Chemistry. With 168 Illustrations. Philadelphia: Lea Brothers & Co. 1885.

This work is made up of Professor Fowne's Organic Chemistry, together with Watts' Physical and Inorganic Chemistry which is itself based upon that portion of Professor Fowne's work which is devoted to Chemical Physics and Inorganic Chemistry. It is, therefore, essentially a new edition of Fowne's Elementary Chemistry, which is so well and favorably known. It comprises three parts: Part I. is devoted to physics; Part II. to the chemistry of elementary bodies; Part III. to the chemistry of the carbon compounds. The theory of chemistry has received its proper share of attention, and the more important of the late discoveries in the science have been introduced. We can recommend the book as one of the best of the many works on chemistry.

## THE RELATION OF MICRO-ORGANISMS TO TUBERCLE.

ONE of the interesting points of the recent series of lectures by M. Bouley before the Museum of Comparative Pathology at Paris, is his treatment of the pathogeny of tubercle. According to Bouley, tubercle is a generic name applicable to certain little nodules or tumors formed in the lungs and other viscera as the direct consequence of an irritation, caused at the points where these tumors appear, by a living parasite. Tubercle comprises many species. To begin with the vegetable world, what are those little tumors called galls but *tubercles* determined by the presence in the tissues of the plant of ova which certain insects have deposited there after piercing the part with their terebra? Around these eggs the vegetal tissue under the irritation undergoes proliferation, and a real tuberculous neoplasm, the gall, is the result.

The researches of Professor Cornil tend to show that between tubercle properly so-called (that of phthisis) and the swelling which results from the arrest in a fine arteriole of a nematoid ovum or embryo there is anatomically no difference.<sup>1</sup> Launani deduces this conclusion from the histological examination made by him of the nodosity constituted by the irritant action of the ovum of the *strongylus casorum*; "that the specific agent of tuberculosis acts in the same manner as the eggs of the strongylus, and inflicts its first mischief on the blood-vessels in which it has penetrated."<sup>2</sup> It is a striking fact that all viruses by the local inflammatory reactions induced by their presence cause similar results; growths are formed, composed of cells and nuclei, sometimes blocks of protoplasm with many nuclei (giant cells); these neoplasms are always characterized by paucity of bloodvessels and a tendency to ulceration and fatty degeneration. The agamous strongyli, which form in the bronchi or muscular tissue nodules in which they become permanently imbedded, produce morbid growths easily distinguished by the presence of the parasite visible to a low power; the lesions of tuberculosis, of syphilis and of glanders, are not thus readily distinguishable. In fact, the most careful study even with

the help of the microscope (but without special staining processes), of the tubercular neoplasms of these respective specific agencies, fails to determine any absolutely differentiating characteristic. On this point, the most competent histologists are agreed. Other factors must be invoked for the purpose of differentiation, such as the subject of the lesion, the clinical history and known aetiology, the presence or absence of Koch's bacillus.

A striking example of the way viruses work in the animal economy (and by *virus* we now understand *contagium vivum*), is furnished by that familiar disease known as *rouget* in swine. The objective characteristic of this disease is the dissemination on the surface of the skin of red spots and patches more or less diffused. The pathological anatomy of to-day warrants us in considering those patches as the seat of the pululation in the *rete mucosum* of the skin of the virulent elements of this rapidly fatal disease. Now that the special microbe has been isolated and cultivated, nothing is easier than to obtain the repetition of this disease on healthy animals by inoculation of the remote products of culture; after a few days of incubation there appear on various parts of the integument the red spots which are an expression of the irritating presence and multiplication of the microbe, just as the pustules of small-pox are the expression, under another form, of the pululation in isolated or confluent places on the derm of the living element of this dire malady.<sup>3</sup>

The same interpretation of symptomatic and anatomical facts is applicable to glanders and other virulent diseases in their relation to the external or internal lesions which accompany them, (we may also cite in this connection trichinosis, caused by the larva of the trichina). After a masterly *résumé* of these data, Bouley, to whom we are indebted for much scientific philosophizing, shows that phthisis and all the tuberculous lesions are amenable to the same explanation. "How is it with true tubercles, those of phthisis—are they also the expression of a local irritant action, determined by a special element which constitutes their nature, like the strongylus or the ovum of the nematoid in its relation to the little tumors of tuberculous appearance of which it forms the central nucleus and is the causal condition? A legitimate induction authorized us to give an affirmative answer to this question before the specific causal agent was found; when it was recognized that tubercle is not histologically different from the neoplasm investing a microscopic strongylus, an ovum or filaria in the small bloodvessels, it was logical to conclude from the known etiology of the latter that the former had a similar etiology. To-day the demonstration is actually made that the tubercle of phthisis, like that of glanders, has the same significance, as an anatomical fact, as that of the *helminthiatic* tuberculosis, that is to say, that it proceeds from a living element which is the bacillus discovered by Robert Koch."

## MEDICAL PROGRESS IN JAPAN.

WE find in the *Japan Weekly Mail*, under date of August 15, 1885, an interesting sketch of a report prepared by Dr. W. N. Whitney and published by the Asiatic Society on the "History of Medical Progress in Japan." It shows most vividly the enormous difficulties under which the earnest students of that land found themselves in their search for the light of Western science. These difficulties arose originally from the restrictions placed during two centuries upon European intercourse by the oppressive government of the Shogun (one is irresistibly tempted to read the word as an Oriental misprint for shotgun), and the almost hopeless labor in the absence of dictionaries and European assistants in translating the text-books of Europe into the Japanese tongue. The way in which the first such translation came to be made is almost a romance in the history of medicine.

One Sugita was a physician in the service of the Prince of Nakatsu, and apparently a faithful student in the light he had. In 1767, he made a copy of the diagrams contained in a work on surgery (Hastel's?), which he had contrived to borrow; and a few years later, in 1771, he became possessed, through the kindness of a friend at court, of two other books in Dutch, one of which was a work on anatomy (Pafel Anatomica, by John Adams Kurumans). In looking over this latter book, his attention was drawn to numerous discrepancies between it and what he had been taught was the anatomy of the human frame. Whereupon, to use his own words, "he was seized with a great desire to make practical observations, and to compare them with the diagrams already copied."

Opportunity offering shortly after in the privilege granted him to witness a dissection at the execution grounds of Kotsu-ga-hara (Plain of Bones), near Asakusa, Tokyo, he joyfully availed himself of it, having first invited his friends Mayeno Riokaku and Nakagawa Kiyôwan to accompany him.

The "subject" was an old woman, who had been condemned to undergo decapitation for her crimes. The dissection was conducted by an old executioner, who had had some previous experience in this kind of work, an occasional duty which was at that time performed exclusively by men of his class.

Of the dissection, Sugita says:—

"As the executioner pointed out the different viscera, etc., there being no names written upon these different parts of the human body (as in the tables), we were compelled to be content with what we were told. . . . However, we compared it with the diagrams of the book (which Mayeno had brought with him) and found that there was no difference whatever, while what had been taught in Chinese books as to the six divisions of the lungs, the three divisions of the left liver, and four of the right, as well as the anatomical arrangement of these and other viscera was found to be quite correct." Sugita further tells us, "that Osaka and Fûjimoto, court physicians, had already witnessed some seven or eight dissections, but had been unable to account for the anatomical differences detected by themselves between the actual dissections and what they had always supposed to be the internal arrangement of these viscera, except upon the ground that the anatomical structures of one race differed thus widely from those of others. Stimulated by a desire to understand more of anatomy, and filled with a sense of shame that men of this

time knew so little of the structure of the human body which they professed to understand, Sugita, with his friends, determined to make a thorough study of Dutch, with the hope that they might be enabled to give to their countrymen a Japanese translation of this work on anatomy. As Sugita knew at this time but little more than the alphabet of Dutch, and Mayeno's Dutch vocabulary embraced but a few hundred words, their progress was necessarily very slow and tedious."

Speaking of some of the difficulties they met with, Sugita says:—

"At that time, we did not know anything about such auxiliary words as *de, het, als, and welk*, and therefore, though we might occasionally meet with words that we knew, we could not make any connected sense out of them; for instance, such a simple sentence as 'the eyebrow is hair growing a little above the eye,' was all confusion; and we had to spend a long spring day, even till dark, thinking and thinking, as hard as we could, over it. One day when we came to the nose, it was said that it was the thing that is *verheven*; we did not then have any dictionary, but in looking over the list of words which Riokaku had brought from Nagasaki, we found that it was said that the tree is *verheven* when a branch is cut off, and also, that when a garden is swept and the dirt is put together, it is *verheven*. As usual, we fell to thinking, but could not make it out. A bright thought came to me, that when the tree whose branch has been cut off, heals, the place is slightly elevated, and again, that the dirt accumulated will, of course, be elevated. Then the word must mean 'elevated.' All agreed that this was quite reasonable, and decided that the word should be translated 'elevated.' The feelings of joy which I experienced then cannot be told. I felt as if I had obtained a whole castle full of precious stones."

Gradually, however, with wonderful perseverance, by meeting six or seven times every month, they became better acquainted with the language; and after a while, were able to translate as many as ten lines in a day.

The whole work took four years for translation, during which time it was re-written eleven times; and was finally published by Sugita under the title of *Kaitai-shinsho*, "New Work on Anatomy." He had entertained doubts as to the safety of publishing this work at the time, as but a little before a book had been suppressed only on the ground that it contained the Dutch alphabet.

The work, however, was well received, and passed through two editions and a revision. It consisted at first of three volumes, but having been revised some years later by Udagawa Genshin, it was enlarged to thirteen volumes, and was called *Han-tei-ki* (an outline of the principles of medicine). Sugita, together with his friends, Mayeno and the others who had assisted in the work, received many honors, and a great number of students flocked to them from all parts of the country.

## THE MASSACHUSETTS BOARD OF HEALTH, LUNACY, AND CHARITY.

OUR esteemed contemporary, the *Boston Herald*, in its issue of the 14th inst., gives an excellent statement of the reasons why the present Board of Health, Lunacy, and Charity, should be abolished and an independent State Board of Health re-established, quoting the opinions of several persons well informed in the matter, who were also thought to represent the general feeling of the community. We quote from the article as follows:

"The Board of Health, Lunacy, and Charity is on its last

legs. It has become unwieldy, quarrelsome and inefficient, and it is very probable that the Legislature will put an end to its existence next winter. Public health has become a victim to lunacy and charity. It is time the curtain was rung down."

The above-noted remark of a well-known physician seems to reflect the opinions of a large proportion of the medical fraternity, and is a view which appears to be entertained by many whose familiarity with the history and the inner workings of the board, as well as their political sagacity, gives to their observations special interest and significance at this time.

Dr. Abbott, health officer of the board, said that he should take his position squarely in favor of division, in the interests of harmony and for securing better work in sanitary directions. "A Board of Health," said he, "could devote its entire energies to this work, and not be obliged to fritter away its time discussing the transfer of insane patients and kindred questions. Almost every State in the Union has its board of health. These boards divide up into a number of committees, and are thus enabled to do an amount and a variety of work which a combined board, like our own, cannot accomplish, and which, in the discussions of mixed questions of health, lunacy, and charity, overlook many important matters."

Dr. Henry P. Walcott, of Cambridge, formerly health officer and later member of the board, said: "I believe that the present board has failed utterly and entirely. It looks as if it will go to pieces this winter. I advocate the reconstitution of the board of health, without any reference to the present organization. Then I think we shall be clear of the politicians, whom sanitarians cannot hope to escape under the existing conditions of things, with the enormous patronage at the disposal of the charity department."

Dr. H. L. Bowditch, formerly member of the board and chairman of the State Board of Health, was most earnest in his advocacy of a division, saying that "practically, the boards were united because of a fear of Butler and his outcry against commissioners, ostensibly for economical reasons, and an imitation of the local government board of England, where a union of health and charity was supposed to be effective. Within a week he had received a letter from an eminent medical man in England, whose name he was not at liberty to use, but which would carry weight, in which he states that 'the sanitary work of England is being entirely upset by this local government board.' The Board of Health, Lunacy and Charity is now virtually without spirit in sanitary matters, and of little value."

Dr. C. E. Folsom, for years connected with the board said: "The present management is far from a success. The health work of the board has deteriorated wonderfully, and this is said with a full appreciation of the efficiency of Dr. Abbott, who does what can be done under the circumstances. None of the board are doing much in this direction, and it is next to impossible that the same set of men should intelligently direct such diverse interests. I think there could be no possible clashing of interests or waste of money if there are two or three separate boards, and the manifest advantage would be in having men who should intelligently direct the work of a single department. I am in favor of a board of health, a board of charities, and a lunacy commission, which should be an advisory board. The present board has virtually driven away one by one all those who have any special knowledge of health matters, with the exception of Dr. Green, who has been recently appointed. I believe that the members of the Legislature will favor this change."

Dr. George B. Shattuck, editor of *The Medical and Surgical Journal*, said: "The boards were consolidated ostensibly for economical reasons. It will be difficult to prove that such economy has been obtained. On a board of this kind it is difficult to get men who have a proper amount of knowledge to work together, and, after you have secured such men, you take up their time in the consideration of a variety of questions, in some of which they do not and cannot be expected to feel an interest, and their task becomes a most thankless one. Those people who are in favor of the present system will claim that it is similar in principle to the local government board of England, which they say works successfully. The comparison is not a just one. In England the board has a large corps of skilled, well-paid, experienced health officers, who divide the country into districts. Our board is anomalous, cumbersome and unwieldy. It transacts public business, if at all, neither harmoniously nor expeditiously. Of course there are always men who can be found to serve for the sake of official position on any kind of a board, but they are

not men who would give time to the serious consideration of the duties involved, and if they should the public would wish they hadn't. The difficulties experienced by the competent medical and scientific men who have been on the board, in their efforts to accomplish anything, is in itself proof sufficient of the undesirability of the present combination. I advocate a board of health as a separate organization. There is plenty of work for it to attend to if it does it thoroughly. The more thickly settled the State becomes, the more essential will it be to have a thoroughly good central sanitary organization, guided and directed by earnest, eager and specially educated men. In view of past experiences, if such men can be induced to give their services, and if they can be protected from the interference of politicians after having entered upon their work, then the people will receive an increased benefit and a protection most striking, by comparison or contrast with what has gone before."

Dr. Samuel Green, ex-mayor of Boston, and a member of the Board of Health, Lunacy and Charity, was next called upon. He said: "I have the highest respect for my associates upon the board, but I have no hesitation in saying that there is not one man among them who is an expert on mental diseases, and yet it is a board of health, lunacy and charity. Furthermore, I object to the system which combines in a single board three interests which do not belong together. Personally, I favor an entire separation, and I think that the great body of physicians are unanimously in favor of a division, and the creation of a board of health made up of experts on sanitary science. Such an organization could command the best medical opinion, would enjoy the confidence of the community, and find a wide field for usefulness. In case a division is effected I have every confidence in the ability and willingness of Gov. Robinson to appoint a board of health which will be entirely satisfactory to the great body of physicians."

Dr. C. D. Homans, president of the Massachusetts Medical Society, expressed himself in a decided manner as being in favor of a separation. The health work had deteriorated greatly since the consolidation.

The opinions above quoted so fully reflect the attitude of other physicians, whose views were sought, that no further citations of opinions are required to establish the practical unanimity of the medical profession.

Mr. John C. Hendley, the civil engineer, not a physician, a member of the old board of health, and for some three years a member of the Board of Health, Lunacy and Charity, believed that the sanitary work of the board had fallen off greatly since the union. "Meetings," said he, "were occupied in the discussions of all manner of private and petty questions, were prolonged to five, six, or seven hours, and the board, after doing all that it was physically able to do, would have neither time nor strength to consider important sanitary matters; consequently, at these meetings questions of public health have fallen into a subordinate place, almost dropped out of sight. I am in favor of a division. I feel that there is work and scope enough for a board of men of special qualifications, who are willing to devote certain days each month to the promotion of public health. Such matters as the adulteration of milk and food and drugs, the purification of streams, the poison in wall-paper, the sanitary condition of schools, hospitals and prisons, are among the important problems which a board of this kind will have to consider. Upon the board of charities there should be a set of men of leisure, benevolence and pecuniary independence, who would be willing to devote about half of their time to the work. But, perhaps, this work and also the work of the lunacy department, could be better performed by eminently qualified commissioners of charity and lunacy who could devote their entire time to the details of the work, which are now attended to by the entire board, acting as a unit. Thus you see that every man on it, whether well informed or not on a special topic to be considered, is obliged to do the same work which a commissioner would do in less than half the time."

Governor Robinson had stated in October that he was willing to say what he had said months before, that he favored the separation of the State Board of Health from those of lunacy and charity, and that it was his intention to recommend such measures to be taken should he be chosen at the coming election, although he declined to speak on the subject at present.

Mr. F. B. Sanborn talked at length in favor of the present arrangement.

Dr. R. T. Davis, congress-man from Fall River, Hon. David L. Webster and Dr. Alfred Hosmer, former members of the Board, and not *all* medical men, have expressed their very strong objections to the present Board, and at least two distinguished members of the medical profession have declined appointments to it on the ground that they could not serve on such an incongruous Board in a way to do justice either to themselves or to the public.

Massachusetts was the first State in the Union to establish a Board of Health, and the good done by it as shown in its reports, has been a guide and incentive to sanitarians and legislators all over the country, until many other States learned to profit by an example which Massachusetts was wise enough to set and misguided enough to abandon.

It seems as if the time and opportunity for her to re-establish a separate State Board of Health had come, and we hope that the medical profession will use its influence to induce the next legislature to pass the necessary enactments for an *efficient* Board, having a general supervision of all those questions included under the terms "State" and "Preventive Medicine;" among the most important of which are water supplies and drainage, adulterations of food and drugs, prevention and regulation of epidemic and other diseases, the scientific as well as practical investigation of sanitary problems, the registration and tabulation of vital statistics, the supervision of the reports of medical examiners, etc., etc. In dealing with such questions, there is plenty of work for a separate Board of competent, hard-working men, among whom should be a lawyer and a civil engineer.

The president of the Massachusetts Medical Society, in accordance with a vote passed at the last annual meeting of the council of the society, has appointed a committee of five to further this matter, consisting of the following-named gentlemen: Dr. George B. Shattuck, Boston, chairman; Dr. John M. Harlow, Woburn; Dr. Richard L. Houlgdon, Arlington; Dr. A. H. Johnson, Salem; Dr. S. D. Presbrey, Taunton; Dr. Emerson Warner, Worcester, who will be glad of any assistance or useful suggestions. Already the daily press, the *Transcript* and the *Traveller*, has sounded the alarm that there is a report of a combined effort to emasculate the adulteration-of-drug act by placing its enforcement under the pharmacy commission, composed of druggists, and taking it out of the hands of the health department which has been altogether too efficient to please the adulterators. It were better to repeal such a law altogether than not to enforce it. And with all due respect to the Pharmacy Commission, we should be scarcely more startled at a proposal to place the supervision of milk in the hands of the retailers of that article.

#### MEDICAL NOTES.

—Prof. R. Ogden Doremus reported to the New York Medico-Legal Society a supposed case of poison-

ing by cocaine, which had been applied to allay pain from a decayed tooth. The application was followed by the death of the patient, a woman.

—A young woman who lately took a medical degree in Paris has been appointed medical examiner of girls in the municipal schools of Paris, her duties being to see that the girls are not overworked and that they accomplish their tasks under good sanitary conditions.

—The *Northwestern Lancet* says that a young man fresh from college, whence he came with honors and medals, was sent by his father, a practitioner of fifty years' standing, to attend a woman in labor. On making a digital examination, he found the os uteri undilated. After waiting an hour, there being no improvement, he applied belladonna ointment, and endeavored to make forcible dilatation. At the end of another hour, there was still no dilatation; and, being alarmed, he went to his father for assistance; but before they returned the child was born. On examination, the father found that the child's anus was red and patulous, and was liberally besmeared with belladonna ointment. The young practitioner had met with a breech-presentation, and had mistaken the child's anus for an undilated os uteri.

—The composition of the London fog is thus illustrated by the *Lancet*. The behavior of smoke, generally, may be studied by an interesting experiment, easily performed by any smoker of tobacco over his evening cigar or pipe. If he will blow the smoke gently from his mouth into any tall glass or vessel—even a tumbler will do—he will find that he can fill it by degrees as with a dense fog, and in a still atmosphere he may pour the fog from one glass to another without dissipating much of it. Precisely what happens with the tobacco takes place when we have a fog—that is, a cloud of vapor resting on the earth, the bulk of the fog being smoke. There are other fogs than those made of smoke, but it is easy by a series of simple experiments to convince oneself that smoke, whether of coal, tobacco—the lighter probably,—or any other vapor, may be concentrated by falling and drifting until it becomes a "fog" of considerable density, which may be rolled as a cloud along the surface of the water, or passed from place to place almost as a fluid.

#### BOSTON.

—Dr. A. Gaston Roeth, of the Boston Board of Pension Examiners, whose resignation is said to have been asked for a number of times but was never given, has been summarily removed by the Commissioner of Pensions. Dr. Morton Prince has accepted the position vacated. Dr. J. G. Blake has also been appointed to the Board *vice* Dr. Aborn who is detailed for special duty at Lynn.

—The inspector of State Charities reports that there are now seventeen insane patients boarded outside the hospitals, and that the new system is very satisfactory in every respect. The law requires that these patients should be visited once in three months, but they are in fact visited much oftener, and receive three times as much watchfulness as the poor in our

city and town almshouses. These private boarding-houses oftentimes serve as an intermediate stage between the hospital and complete convalescence; a place where the patient discharged from the hospital may remain until he can take care of himself. The inspector says that the out-patients are not more likely to suffer from neglect than the inmates in the hospitals, probably not so much, inasmuch as they are visited at frequent and irregular intervals. He says that the patients improve when placed upon a farm, and the people who board them seem to get along very comfortably with the patients.

—Apropos of the remarks in a recent editorial in the *Journal* upon the dangers of coal-gas poisoning, we notice by the daily press that last week a family residing in Everett, met with an experience which was nearly fatal to one of them. They went to bed about 9 o'clock in the evening, after putting a lot of fresh coal on the stove. By some accident the dampers remained closed. The man awoke about 4 o'clock the next morning, and found all the three rooms filled with coal-gas. He was just able to crawl to the hall door and open it, and then fell unconscious. After fifteen or twenty minutes he regained his senses, and found his wife and baby, and his wife's sister, who occupied an adjoining room, all unconscious. Physicians were summoned immediately, and the mother and babe found to be nearly dead. They subsequently revived under treatment. The wife's sister remained unconscious for a long time, but at last accounts was mending slowly.

#### PHILADELPHIA.

—Dr. Henry F. Formad will deliver the Mütter Lectures before the Philadelphia College of Physicians on Tuesday and Friday evenings in December and January, on the following subjects: "Morbid States as Influenced by Embryonal Development, Anomalous Structural Peculiarities, Injuries, and the Effects of Lower Organisms, with special reference to Surgical Pathology."

#### NEW YORK.

—Six school children in Newark, N.J., having been recently bitten by a mad dog, Dr. O'Gorman of that city, has obtained by cable the consent of Pasteur to take charge of them, and has started a subscription to pay the expenses of the trip to Paris for those of the children whose parents cannot afford it. Four of the children are to be sent (the parents of two of them refusing to allow them to go), and it is probable that Dr. F. S. Billings, of New York, will accompany them. In the meanwhile, an active warfare is being carried on against the canine race in general in the vicinity of Newark, where there is considerable excitement on the subject.

The latest intelligence is that Mr. Andrew Carnegie has offered to defray the entire expense of sending the children to Paris, and that Dr. H. M. Biggs, one of the instructors in the Carnegie Laboratory of Bellevue Hospital Medical College, is also to accompany the party, with a view to making a special study of Pasteur's methods. Dr. Billings has preserved

the brain and spinal cord of the dog which bit the children, with the expectation of obtaining hydrophobia virus from them on his return from Paris.

—W. B. Ruggles, State Superintendent of Public Instruction, has rendered to the State Board of Health an opinion in regard to the controversy between the Board of Health of the city of Lockport and the Board of Education of the same city, in which he arrives at the following conclusions:

(1) In the absence of small-pox among the children of Lockport, and as a purely preventive measure, the power of exclusion of pupils from the school by reason of their not being vaccinated belongs to the School Board, and not to the Health Board.

(2) In such case, it would not be proper for the local Health officer under direction of the Board of Health, without the consent of the Board of Education, to enter the school room during a session of the school, and then and there insist upon inspecting the pupils, or vaccinating them, or notifying them that they would be excluded from the school unless they were vaccinated.

(3) The only condition upon which the Board of Education is authorized, by the act of 1860, to exclude any child or person from the benefits of the schools is that such child or person has not been vaccinated, not that he or she has not been vaccinated within five years. Therefore, although the State Board of Health may very properly recommend that those who have been vaccinated longer ago than five years should be re-vaccinated, a failure of such child or person to be re-vaccinated within five years would not be a legal ground of exclusion from school under the law referred to.

(4) Exposed as Lockport is to invasion by small-pox from points in Canada, sound judgment would seem to require that all possible reasonable efforts should be made by way of vaccination and otherwise by the local health authorities and the school authorities of the city to guard against the spread of the disease in that locality.

(5) By a careful observance of these statutory requirements and a disposition, on each side, to respect the legal rights of the other, the Health Board and School Board need have no difficulty within their respective jurisdictions in co-operating harmoniously in the performance of these important duties imposed upon them for the good of the community.

—Mr. Carnegie has recently made a gift of \$6,000 for the purchase of scientific apparatus for the Carnegie Laboratory, and has also signified his intention to contribute annually for the encouragement of the prosecution of original medical investigation in America.

—The first human body was incinerated in the new Mount Olivet Crematory at Fresh Pond, Long Island, on the 4th of December, and while there was some little delay and unskilful manipulation in carrying out the process, which can easily be avoided in the future, the result was entirely successful. The person whose body was cremated died about a month ago, and it is said that there are about forty other bodies now awaiting cremation here.

— Gen. Alexander Shaler, President of the City Board of Health, has been arrested and required to furnish \$10,000 bail on a charge of bribery. In the indictment found against him by the grand jury, the first count charges that while acting as a member of the Armory Board, he agreed to vote for the selection of certain city lots as a site for the Eighth Regiment Armory, in consideration of receiving \$9,000. The second count charges him with receiving a release from his indebtedness of \$9,000 to the Hackensack Savings Bank as the price for his vote in the Armory Board.

— The Commission appointed by the Legislature to receive some plan for improving the water supply of

Albany have presented the results of their investigations, lasting for about six months, in a report to the Common Council of that city, in which they unanimously recommend the adoption of the driven-well system on the sand plains north of the city, near Pleasure Island, at a cost of \$450,000 for furnishing a million gallons daily. Dr. Albert Vanderveer, of Albany, President of the New York State Medical Society, is one of the members of the Commission.

— At a fancy bazaar just held at Yonkers on the Hudson, for the benefit of St. John's Riverside Hospital of that place, the handsome sum of \$4,000 was realized.

## REPORTED MORTALITY FOR THE WEEK ENDING NOVEMBER 28, 1885.

82 Massachusetts Towns	—	—	—	—	—	—	—	—

Deaths reported 1,161; under five years of age 519; principal infectious diseases (small-pox, measles, diphtheria, and croup, whooping-cough, erysipelas, fevers, and diarrhoeal diseases) 263, consumption 287, lung diseases 161, diphtheria and croup 159, typhoid fever 29, scarlet fever 21, malarial fever 17, whooping-cough 10, cerebro-spinal meningitis eight, measles four, purpural fever four, small-pox one. From scarlet fever, New York eight, Philadelphia five, Pittsburgh, four, Baltimore, New Orleans, Fall River and Cambridge one each. From malarial fever, New York eight, Philadelphia three, Baltimore, New Orleans and Charleston two each. From cerebro-spinal meningitis, New York and Fall River three each, Philadelphia and Worcester one each. From measles, Baltimore two, New York and Boston one each. From purpural fever, New York, Philadelphia, Baltimore and Nashville one each. From small-pox, New York one.

In 110 cities and towns of Massachusetts, with a population of 1,228,124 (population of the State 1,911,465), the total death-rate for the week was 18.18 against 14.94 and 16.26 for the previous two weeks.

For the week ending November 14th, in the Swiss towns, there were 23 deaths from consumption, lung diseases 22, diarrhoeal diseases seven, typhoid fever four, erysipelas two, small-pox and whooping-cough each one.

The death-rates were: at Geneva 11.1; Zurich 13.6; Basle 15.9; Berne 16.4.

In the 28 greater towns of England and Wales, with an estimated population of 8,996,116, for the week ending November 14th, the death-rate was 19.4. Deaths reported 3,304; infants under one year of age 780; acute diseases of the respiratory organs (London), 118, measles 87, whooping-cough 69, scarlet fever 47, diphtheria 48, fever 33, diarrhoea 33, small-pox (Liverpool three, Bristol and London one each) five.

The death-rates ranged from 12.9 in Nottingham to 26.5 in Preston; Birkenhead 15.1; Birmingham 17.7; Blackburn 22.7; Hull 11.8; Leeds 15.8; Leicester 13.4; Liverpool 21.6; London 19.6; Manchester 22.1; Sheffield 17.9; Sunderland 18.7.

In Edinburgh 17.1; Dublin 21.1; Glasgow 29.7.

The meteorological record for week ending November 28th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole of the United States Signal Corps:—

Week ending	Barometer.		Thermometer.		Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM NOVEMBER 28, 1885, TO DECEMBER 4, 1885.

VICKERY, R. S., surgeon and major, United States Army. Relieved from the assignment as Acting Medical Director, Department of Colorado, to date the 16th inst. S. O. 200, Department of Colorado, November 28, 1885.

WINE, C. K., assistant surgeon and captain. Assigned to duty as Post Surgeon, Benicia Barracks, and attending surgeon at Benicia Arsenal, California. S. O. 109, Department of California, November 20, 1885.

#### OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING DECEMBER 5, 1885.

ALLICK, HAMPTON, surgeon. Ordered to "Alliance" as relief of Surgeon G. P. Bradley.

BRADLEY, GEO. P., surgeon. Ordered to naval hospital, Philadelphia.

STAEFER, JOSEPH, assistant surgeon. Detached from naval hospital, Philadelphia, and ordered to "Minnesota."

GAIXES, J. H., passed assistant surgeon. Detached from naval hospital, Washington, and ordered to the "Dolphin."

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE FOR THE TWO WEEKS ENDING DECEMBER 5, 1885.

WYMAN, WALTER, surgeon. Granted leave to attend meeting of American Public Health Association, December 3, 1885.

BENSON, J. A., passed assistant surgeon. Granted leave of absence for fifteen days, November 28, 1885.

ARMSTRONG, S. T., passed assistant surgeon. Granted leave of absence for eight days, November 20, 1885.

WANDEN, EUGENE, assistant surgeon. Granted leave of absence for thirty days, November 28, 1885.

WATKINS, R. E., assistant surgeon. To proceed to Galveston, Texas, for temporary duty, November 20, 1885.

#### SOCIETY NOTICES.

SUFFOLK DISTRICT MEDICAL SOCIETY. OBSTETRIC AND GYNÆCOLOGICAL SECTION. There will be a meeting of this section at the large Medical Library Room, 19 Boylston Place, on Wednesday evening, December 10th, at 7.45 o'clock. Communications. Dr. O. W. Doe, "The Advisability of Inducing Abortion in Cases of so-called Incontrollable Vomiting of Pregnancy." Dr. E. W. Finsling, "Exhibition of Preparations of Septic Bacteria, with Observations on Puerperal Septicæmia." Drs. Frances Minot, J. P. Reynolds, A. D. Sinclair, W. E. Boardman, C. M. Green, and H. C. Ernst will take part in the discussions. Refreshments after the meeting.

JAMES R. CHADWICK, M.D., Chairman.

ROBERT B. DIXON, M.D., Secretary.

BROAD ISLAND MEDICAL SOCIETY. A quarterly meeting will be held in Lyceum Hall, 62 Westminster Street, on Thursday, December 10, 1885, at 10 o'clock. Papers. Dr. G. F. Keene, "A New Method of Treating Colles' Fracture." Dr. F. P. Capron, "Nasal Catarrh, its Immediate and Remote Effects." Dr. G. C. Wiggins, "Clinical Observations on Thrombæmia."

G. D. THERY, M.D., Recording Secretary.

#### RESIGNATIONS.

Dr. J. P. Reynolds has sent to the Corporation of Harvard University his resignation of the Chair of Obstetrics in the Medical School.

Professor R. A. F. Penrose has resigned the Chair of Obstetrics and Diseases of Women in the University of Pennsylvania.

#### BOOKS AND PAMPHLETS RECEIVED.

A Study of Epilepsy; a Paper read before the American Medical Association. By J. J. Caldwell, M.D., Baltimore.

Basic Aural Dyscrasia and Vocal Deafness; a New System of Aural Therapeutics and Pathology (Reprinted from the Dublin Journal of Medical Science), also, Notes on the Deafness, (Reprinted from the Lancet.) By Robert T. Cooper, M.A., M.D., University, Dublin. London: Baillière, Tindall & Cox. 1885.

The Physiological and Pathological Effects of the Use of Tobacco. By Robert Amory Hare, M.D. (University of Pennsylvania). E. Sc. Fiske Fund Prize Dissertation, No. XXXIV. Philadelphia: P. Blakiston, Son & Co. 1885.

Student's Aids Series. Aids to Medicine, Part III (Double Part) Diseases of the Brain and its Membranes, of the Nervous System, of the Spinal Cord and of the Ear. By C. E. Armand Semple, B.A., M.B., Cantab, etc. New York and London: G. P. Putnam's Sons, 1885.

Observations upon the Mutual Relations of the Medical Profession to the State. Address by Donald Maclean, M.D., President of the Michigan State Medical Society. Delivered before the Society at Port Huron, June 10, 1885. Lansing.

A Case of Fatal Ear Diseases, Beginning as a Circumscribed Inflammation in the Outer Half of the External Auditory Canal. By Charles J. Kipp, M.D., of Newark, N. J. (Reprinted from the Transactions of the American Otological Society, 1885).

The Physician's Visiting List. (Lindsay & Blakiston's) for 1886. Thirty-Fifth Year of its Publication. Philadelphia: P. Blakiston, Son & Co.

A Guide to the Practical Examination of Urine. For the Use of Physicians and Students. By James Tyson, M.D. Fifth Edition, Revised and Corrected. With Colored Plates and Wood Engravings. Philadelphia: P. Blakiston, Son & Co. 1886.

Rectal Medications. By D. W. Cathell, M.D. (Reprint from Transactions of the Medical and Chirurgical Faculty of Maryland, 1885).

A Manual of Operative Surgery. By Lewis A. Stimson, B.A., M.D., etc. Second Edition. With 342 Illustrations. Philadelphia: Lea Brothers & Co. 1885.

Annual Report of the Surgeon General, United States Army, 1885.

Organic Materia Medica and Therapeutics. By James Young Simpson, M.D. In accordance with the Sixth Revision of the United States Pharmacopœia. New York: J. H. Vail & Co. 1885.

The Friedrichshall Apertien Natural Mineral Water: its composition, Physiological Action, etc. London, 1885.

Five Thousand Facts that Everybody Wants to Know. The Fifth of many Books. Compiled by W. R. Adams. Chicago: A. H. Andrews & Co. 1885.

Manuel des Injections sous-cutanées par Bourneville, Médecin de Bicêtre et Bricon Docteur en Médecine. Second Edition. Revue et Augmentée. Paris. Librairie du Progrès Médical, 1885.

THE PRESENT SYSTEM OF APPOINTMENT OF MEDICAL EXAMINERS BY THE STATE OF MASSACHUSETTS.<sup>1</sup>

BY W. C. B. FIFIELD, M.D.

In an unguarded moment I promised to read before this Society a paper bearing the title expressed on the cards for the evening.

## THE PRESENT SYSTEM OF APPOINTMENT OF MEDICAL EXAMINERS BY THE STATE.

A somewhat extended experience in criminal cases before the courts suggested this paper. I ask the forbearance of my hearers towards this crude and hasty production, and I must most distinctly assert that anything seemingly severe or critical is directed towards the system, and not against the Examiners themselves.

The office of Coroner, now extinct in this State, is of great antiquity, and has been held in high respect for centuries. It still exists in almost all civilized countries. The organization of coronerships varies somewhat in different commonwealths. Some have coroners in each village, town, and city. Independent of every other officer, they are called upon when occasion arises for their services, summon their juries, investigate their cases, and return their findings to the proper authorities. Their duties end when such return is made.

In one country at least, more than this is required. The coroner of a community must, if in his judgment a searching inquest and a thorough post-mortem be required, notify a still higher official, the coroner for the county or province, presumably a man of more advanced education and practical skill and higher judgment. This personage being presented with the facts of the case, proceeds to a careful and searching investigation of all facts bearing on the case, and personally conducts the autopsy, guided by and in strict regard to rules laid down by superior authorities.

Not yet is the paternal government satisfied. The findings of the county coroner must be submitted to a Board sitting at the capital of the State, and representing all the most distinguished medical jurists the country can produce. These findings are winnowed and sifted, and only then is the case delivered over to the representatives of the law, or withdrawn from public notice.

In our own Commonwealth, as I before said, the office of Coroner is extinct. Let us ask why it is gone, and what has come in its place. At once the answer springs to our lips, that the abuses and corruptions of the first demanded that it die, and that the office of Medical Examiner has been born and now has attained some age. Let us again ask whether the time has not now come when this should pass away and give place to something better.

We have said that the abuses and corruptions of the office of coroner brought about its death. What those evils were is yet shortly told, and are fresh in the minds of men not arrived at the period of creaking old age. They were ignorance, avarice, and jealousy. The coroners of country towns were as often as not, chosen from the most ignorant and illiterate of the population. Incapable of distinguishing between fact

and falsehood, often cruel and harsh, because ignorance is always cruel and harsh.

In the great cities, avarice and jealousy took the place of the ignorance of the country town. Coroners constantly ordered post-mortems to be made, often when needless, thereby pleasing their favorite doctor; or the doctor being the coroner, ordered one to please himself. Add to the post-mortems the fact that the same coroner took care to always have nearly the same men on his juries. Add again the astonishing length of time these juries could sit, and you come near the answer, that both coroners and juries gained a comfortable living in this way.

Very jolly and profitable to me in early professional life were these inquests. The kind old coroners who adjourned early, and day by day; toothsome and wholesome the lunches, and soothing the cigars paid for by the county. *Vale. Vale.*

Jealousy also played its part. Coroners had their men out to act as deplorers, or, as a military acquaintance always terms them, deplorers; and rapid were the legs, and nimble the tongues of the deplorers when a body was in sight.

We now come to the second question, whether or not the time has come when the present system of medical examiners as appointed by the State ought to perish and give place to something better. If we argue in the affirmative, we must state the convictions that lead us hither.

The exact number of medical examiners I do not know. Appointed by the State, they undergo no examinations to determine their fitness for the post. They should be in every instance well-bred and well-instructed gentlemen, competent from education and professional training to fill this very responsible post, not to be entered into carelessly and thoughtlessly, but soberly and seriously, well weighing its many obligations; able to make an exhaustive *post-mortem*, with full knowledge of what will be demanded by the law; possessed of sufficient knowledge of chemistry and toxicology to recognize the *post-mortem* appearances produced by ordinary poisons, and to determine their presence by chemical analysis.

Will any one say that the medical examiners in general come up to this standard, or that such standard can be maintained by any means short of a rigid practical examination of each candidate for the office?

I believe that the appointments are not made either by fame or from careful questioning by the Executive or by an expert proxy. I believe that they are made rapidly, perhaps are *sometimes* obtained by the din and clatter of the agents of those who think that a commission would give them consequence in the communities where they live. I do not believe that a careful canvass of the State would show that the medical examiners are invariably the best and most competent of the physicians. Such do not seek the office.

Yet when we reflect for a moment on the tremendous power in the hands of the medical examiner — the power to arouse suspicion, to cast odium never to be removed in country towns; power indirectly to bring about imprisonment and ruin to parties against whom no real evidence exists — we shall begin to demand that the appointing executive shall sit as a refiner at his fire "till free from dross the silver runs below."

Moreover, we must bear in mind the great cost to a county of a capital case, or even of cases of murder in the second degree where it is known or suspected that

<sup>1</sup> Read at the Boston Society for Medical Improvement, Nov. 23, 1885.

the report of the medical examiner is deficient or in error. We must think also of high officials, such as attorney-generals, district attorneys, and eminent counsel being led into errors as to indictments, and evidence, exposing them to mortifying exhibitions of themselves before the court and jury, through the incompetence of the medical examiner on whose skill and knowledge they had relied.

Then, and chief of all, the prisoner at the bar, in constant danger of a miscarriage of justice, has he not a right to demand that the arm of the government shall be thrown around him as a shield and defence, as well as for an instrument of punishment. Let him not be stricken down as with a club in the hands of a blind man. Considering these things, should not the office seek the man, seek the best, the most learned, the most upright, the most competent?

Is such the case in this Commonwealth? One cannot but praise a most excellent district attorney for his recent order to medical examiners in his district: "In cases of suspected murder or manslaughter, employ an expert to be with you." Men and women have doubtless languished in jails from suspicion and conviction of crimes which have had no existence save in the minds of untrained and incompetent medical examiners. Per contra, doubtless many criminals escape from the same cause. Matters were surely not much worse in the days of coroners, whose long deliberations certainly gave opportunity for the suspected to employ help, both medical and legal.

I am informed on most credible authority of an action brought to compel the payment of one hundred dollars by a medical man to an agent who should obtain the appointment of medical examiner, and who did procure it. Judgment for the plaintiff: appealed to a higher court. The writer has for many years been employed by the government, and once by the defence, in capital cases, and in those of the second degree, and has been sometimes astonished at the lack of qualification on the part of medical examiners for the duties they had assumed.

So firmly was this fixed in the mind of perhaps one of the ablest district attorneys Massachusetts has ever had, that, in the latter years of his practice at the bar, he absolutely refused to go to the grand jury with a case seen by a medical examiner unless it had been first submitted to an expert's guidance, not late, but early, before the *post-mortem* if possible, at any rate, before the body had lain long enough in the grave to destroy important evidence to be obtained from it. The writer has had such body disinterred hours after it had been examined, and miles away from the spot where the crime had been committed.

I well remember the dismay of the late Charles R. Train on reading the indictment of a famous case of murder containing only one count, namely, that death occurred from a shot in the head, and that the victim had died in a certain town in Norfolk County. Scarcely an organ of the body except the brain had been inspected and the writer set up for the defence the points that the death came from drowning; that it came from suffocation by a scarf tied around the neck; that it came from Bright's disease; that it came from disease of the heart, and that she did not die in the town named, but in another. More than a year ago the writer was sent by the government to investigate a case of supposed murder in Massachusetts. The first medical examiner, on being

called to view the corpse, had, it was told me, thrust his hand beneath the overcoat, and had rendered a verdict that the cause of death was disease of the heart. The second examiner, brought in obedience to popular clamor, made an autopsy, found no disease of the heart, but did find what he honestly believed to be a dislocation of the atlas from the skull. Yet on taking up the body there was no evidence of either fracture or dislocation having ever existed. In this examination, the writer had the advantage of the presence of a most excellent medical examiner employed by the defence.

The supposed murderer had been arrested and had, I think, lain in jail some six weeks. So also had a man and his wife who lived in the house at the time of the supposed murder, and whose evidence it had been thought was too valuable to allow of their being at large.

Not long ago a teamster passing along a somewhat lonely road, perceived a horrible smell which seemed to come from a field near by. Dismounting from his wagon and entering the field he saw lying near the wall the dead body of a man, pretty well advanced in decomposition, for the weather was very hot. He notified the authorities: the medical examiner, who viewed the body, declared no suspicious circumstances existed, and ordered the burial of the body. Days afterwards, in consequence of some information picked up by a constable, the corpse was exhumed, re-examined, and three ribs, and I believe the sternum, were found broken, and either the pericardium or pleura found to contain a quantity of blood. The man was probably killed by his adversary kneeling upon him, or, as one man expressed it "jouncing him." Here the older coroner system would perhaps have worked better. With its delay, and its large jury of neighbors, the suspicious circumstances would most likely have been brought forward. Conviction and sentence of the criminal duly took place.

Only recently the writer was called by the government to read over the report of a medical examiner, who had returned in a case, which it was supposed could be tried as murder in the second degree, that he had reached the following very extraordinary conclusions, namely, "That the deceased had come to her death from typhoid fever, complicated with cerebro-spinal meningitis following a blow struck with a small stick on the right buttock six months before." The skull had not been opened, but the diagnosis of cerebro-spinal meningitis had been founded on the fact that a part of the lumbar vertebra had been chiselled away to a small extent and blood had been seen on (and within?) the dura mater. The Grand Jury found a bill for assault of the man on his daughter because she did not rise early enough in the morning to please him, and fined him one hundred dollars or five months in the House of Correction. He preferred the latter and boarded it out.

At a recent trial that cost the county a great deal, for to the medical examiner there was added four experts and but one was brought forward for the defence, this remarkable verdict was rendered.

Mark — a jury between the country and the prisoner at the bar. On the first count of the indictment: By striking five mortal wounds of which she died. Not guilty. 2d. By inflicting twenty wounds and exposing her to the weather (thermometer at 8° below zero). Not guilty. 3d. By some means to the jury unknown. Guilty." It is stated that the prisoner smiled, as well

he might. Sentenced to five years in the State Prison.

My thoughts on the present system of appointment of medical examiners by the State are that, it is insufficient for the protection of the citizens of the Commonwealth; that the best, that is, the most highly trained men, are not secured for the office; that even one such man in a county, would be better than one less competent in each town; that the office is sometimes secured by unworthy means; that the payment of the office is insufficient, this goes without saying; that the Commonwealth should appoint a commission composed of the very best medical jurists in the country, who shall thoroughly examine all applicants for the office of medical examiner, and recommend those who pass to the Executive for appointment.

The writer desires to say that whilst such men as Dr. Draper, Dr. Harris, and others are among the medical examiners the evils of incompetence will not be very severely felt, particularly as the order has gone forth, in one district at least, for the employment of experts by medical examiners. A great and instant need for reform and advance is at hand. Any one who has a spark of justice in his heart, or who has feeling for the misfortunes and distress of others must know this need.

The ideal must become real. men must be found who will profoundly study medical jurisprudence in its highest and most lofty conditions wherever it is best taught; in Paris, if need be, where Tardeu did his splendid work; at the Morgue, whose shelves are daily laden with the victims of crime, or sorrow, or of the madness of despair; where a learned professor turns all these to use in his lectures; in the teeming city where Caspar lived and died. All appliances must be possessed by such men with knowledge to use them; these, or a selection from their number, should form a commission of last appeal. In my imagination I see such a Board sitting in judgment and furnishing to the officers of the law sifted truth, each member vying with the other to present all sides of the case with perfect fairness.

I shall see the courts free from experts trying each to serve the master who feeds him, for it is almost as easy for a camel to go through the eye of a needle as to avoid bias. I have heard medical examiners even, asked the question, "Doctor, do you want this prisoner convicted?"

In each shire town I hope to see perhaps a lesser, but not feeble luminary of medical jurisprudence, who shall gather facts from village and hamlet, and submit the same to the Commission. Even so may this come and come quickly.

#### APPENDUM.

As the above may seem Utopian, not to be realized for an age, I would offer the following substitute:

That as occasions offer themselves to the Executive, from the death, or resignation, or removal of medical examiners, their places shall be filled by none except those who shall furnish certificates from professors of colleges holding the position of teachers of Medical Jurisprudence, that they are well fitted for the post.

—The *Medical Record* states that at the recent election in England, eleven cities elected medical men as mayors.

### A CASE WHERE LITHOTOMY WAS TWICE PERFORMED WITHIN FOURTEEN MONTHS, WITH REMARKS ON THE RECURRENCE OF STONE IN THE BLADDER.

BY REGINALD HARRISON, F.R.C.S.,

Surgeon to the *Liverpool Royal Infirmary* and *Lecturer on Clinical Surgery* in the *Victoria University*.

CASES of recurring stone in the bladder requiring removal by lithotomy are sufficiently rare to need no apology for their narration. The particulars of this instance are as follows:

Thomas S., aged sixty-two, was admitted into the Royal Infirmary under my care in July, 1884, suffering from symptoms of stone. On examination the bladder was found to contain more than one stone. The prostate was large and considerably impeded the introduction of the necessary instruments for sounding and exploring the bladder. Under these circumstances, I selected lithotomy with the view not only of removing the stones, but of improving the condition of the prostatic urethra by the method I have already brought under notice.<sup>1</sup>

On July 25, 1884, I performed lateral lithotomy and made a free section of the prostate which, by the elevation of its floor from hypertrophy, rendered access to the bladder somewhat difficult with the forceps. I removed two and a quarter ounces of stone, which broke in removal. Allowing for portions that were lost during this piece-meal extraction, the stones must have weighed about three ounces. The calculi were chiefly phosphatic, with a uric acid nucleus. The bladder was carefully explored both with straight and curved forceps, with the finger, and finally was well washed out from the wound with a Higginson's syringe. The section of the prostate referred to rendered the various manipulations quite easy. One of my bladder drainage tubes was introduced. There was some free oozing after the operation which necessitated a plug of lint soaked in turpentine being inserted by the side of the tube. The patient made a good recovery; the bladder drainage tube which was used for rendering the section of the prostate permanent, was changed several times and was not finally removed until six weeks after the operation. The patient left the Infirmary apparently well with a sinus through which urine passed in small quantities. Considering the time the drainage tubes were retained for improving the prostatic urethra, I did not attach any importance to this, and, guided by other experiences of the kind, assured the patient that the wound would soon heal.

After he left the Infirmary, though he returned to his work, his bladder never quite recovered itself; the wound did not entirely close, and he suffered more or less at times from chronic cystitis. These circumstances led me to believe that the bladder was sacculated, but I could detect nothing more.

In August, 1885, my house surgeon, Dr. Bristow, sounded him and thought he felt another stone. On a subsequent examination I confirmed the diagnosis, and on September 12, 1885, I again performed lateral lithotomy for him on the old line, in the course of which there was a small sinus remaining from the previous operation. The operation was perfectly easy, the access to the bladder being greatly improved, for on this occasion, the largest sized staff could be readily passed. I removed a stone which, with its encrust-

<sup>1</sup> On the treatment of certain cases of prostatic obstruction by a section of the gland. Transactions International Medical Congress, Copenhagen, 1884.

ing shell of friable phosphates, weighed exactly one ounce. Surgeon-General MacKennon and Dr. Frank E. Cannes were present at the operation. A double bladder tube was introduced for drainage, and retained for a few days, when it was withdrawn; the patient was up on the twenty-third day, and left the Infirmary exactly five weeks after the operation with the wound soundly healed and the functions of the bladder completely restored. He has since reported himself as remaining quite well. No prostatic bar can now be felt nor is there any residual urine.

I was somewhat puzzled at first to explain satisfactorily the course of events in this case. I have mentioned the various processes employed at the first operation, so far as improving the entrance into the bladder was concerned, for the purpose of showing how thorough an examination of the interior of the viscus was necessarily made, both by the finger and by means of different kinds of instruments. It seemed almost impossible that a stone, however sacculated, could, under these circumstances, have escaped detection. Still, on the other hand, when I considered that the wound never completely closed after the first operation, and that in the interval the patient was never free from signs of vesical irritation, it seemed to be probable that the whole of the stone had not in the first instance been removed. A careful examination of the stone itself further convinced me that this was the true explanation. If the mass of calculous material removed at the second operation is carefully examined, it will be seen to consist, as geologists would say, of two different strata. The inner portion or nucleus of the size of a flattened French prune, evidently belongs to the same period and formation as the calculi removed at the first operation, the outer friable crust of phosphates clearly being of quite recent production. I have no hesitation in concluding that a stone of considerable size escaped detection and removal at the time of the first operation, even in spite of all the precautions which the state of the prostate prompted.

As I have now performed lithotomy in children and adults in about equal proportions, close upon one hundred times, with a mortality of four or five per cent., I think I may plead that both experience and care proved unequal in this instance in avoiding a contingency which, had death happened after the first operation, might have exposed one less accustomed to operate for stone than myself to unjust obloquy and criticism. Hence my desire apart from the general interest of the case to record it. One circumstance afforded me considerable satisfaction, and that was my being able to ascertain beyond all reasonable doubt how feasible it is permanently to improve the condition of the large prostate by its section, as already referred to in cases uncomplicated with stone. One great objection I have had to the supra-pubic operation for stone is that where in addition to a calculus there is a large and possibly obstructing prostate, it affords no opportunity for remedying the latter should this be found practicable, and of permanently removing symptoms which may continue though no stone is left to account for them.

Mr. C. Williams of Norwich, has recently published a case<sup>2</sup> which adds importantly to our knowledge relative to the operative proceedings on the large prostate. It is an instance where he operated twice for stone in a patient over seventy years of age. On the first occasion the whole of the middle lobe of an enlarged

prostate was removed, and subsequently another stone by lateral lithotomy. Referring to what had previously been done, Mr. Williams remarks, "The next point is the condition of the floor of the bladder. Two years and a half had elapsed since the part was removed and no further growth from the prostate had taken place. The wound made by such removal had healed, and the floor of the bladder was soft, even and natural."

Reverting to my own case, in the improved state of the outlet from the bladder may be found the explanation as to how it happened that the sacculus or depression which concealed the stone and rendered a second operation necessary, got rid of its occupant and thus led to the viscus resuming its normal shape and function, as it undoubtedly has.

There can be question that of the various causes which bring about sacculation and changes in the shape of the bladder, anything which obstructs micturition is the most fertile, and in the recognition of this explanation, we have the clearest indication for the correction of this lesion. The case I have narrated may serve to illustrate this point. It may be doubted whether a bladder is capable of becoming so completely sacculated as to conceal a considerable sized stone from detection. One of the best examples of this I recently met with in the pathological museum attached to Queen's College, Birmingham.

As to the frequency of stone relapses, Mr. C. Williams writes, in reference to cases occurring at the Norfolk and Norwich Hospital,<sup>3</sup> "This makes a total of 28 relapses in 1015 operations (lithotrities and operations on females included), between 1772 and 1869, a period of ninety-seven years, and gives a proportion of one in 36, or, of 35 lithotomies (lateral and median) one in 33. All the patients were males, no instance of recurrence having shown itself in the female. In one case a sacculated calculus was left undetected in the bladder and removed with a loose one at a second operation." The case referred to in the last paragraph seems to be similar to the one I have now recorded.

In connection with Mr. Williams' statistics relative to stone relapses, it must be remembered that they are drawn from a locality where calculus disorders are endemic, consequently taking a larger area we may conclude that the proportion of recurrences is still less, a conclusion which my own experience would warrant.

Amongst the causes favoring the reproduction of stone, I believe the large prostate is by far the most frequent, and it seems to bring this about in at least two ways. In the first place, persons who may have been in the habit of voiding renal calculi for years, find after a certain age has been reached that they no longer do so, and continued vesical irritation follows upon the attack of renal colic. The explanation lies in the fact that the prostate has commenced to enlarge and obstruct, and thus stones which previously escaped spontaneously are practically trapped. I am frequently in the habit of removing by crushing, small uric acid calculi formed under these circumstances. In the second place, the large prostate, by permanently altering the shape of the outlet from the bladder, and thus causing urine to be constantly retained, engenders a state of chronic cystitis and excessive mucous excretion, which are the invariable preliminaries to the formation of the phos-

<sup>2</sup> The Relapse of Stone in the Bladder after Lithotomy. *The Lancet*, May 19, 1878.

<sup>3</sup> *British Medical Journal*, June 15, 1878, and November 11, 1885.

phatic stones. In these directions, I think may be often found explanations for the recurrence of stone in instances where there cannot be a doubt that the primary formations had at all events been entirely removed.

## REPORT ON DISEASES OF CHILDREN.

BY T. M. ROTH, M.D.

### CATALEPSY.<sup>1</sup>

THE occurrence of catalepsy in childhood is so rare and the recorded cases so few in number that the report of Dr. A. Jacobi on a girl three years old, a patient at the Mt. Sinai Hospital, is well worthy of mention. Jacobi, speaking in general of catalepsy, states that the only case in a child which has come under his notice besides the one about to be spoken of, occurred in a boy of thirteen who suffered from chorea magna during the space of two years before he died in an insane asylum. His attacks of chorea were very violent, interrupted by intervals of several weeks, in which both his convulsive efforts and his psychopathic condition would improve and would alternate sometimes with brief attacks of catalepsy, with but partial consciousness, diminished or destroyed will power and the waxy flexibility, all of which symptoms are claimed to be those of the morbid condition called catalepsy.

Monti, in his article in Gerhart's "Handb. d. Kinderk.," vol. v., p. 186, quotes but eleven cases met with in children, male and female in about equal numbers, from five to fifteen years, the average age being nine years. Jacobi's case was remarkable from the fact of no previous case having been reported as young as three years, also in the combination of well-marked symptoms of psychic indolence, normal or abnormal temperature, cold surface, anaesthesia, analgesia, "flexibilitas cerea" and diminished patella reflex. The increase of urine during a greater part of the catalepsy was also a remarkable feature, such as is seen in hysteria of both adults and children; but while it contained no sugar and nothing abnormal, excepting large quantities of phosphates, it had the, in children, unusual specific gravity of 1015-1020.

The report of the case is as follows: F. C., aged three, admitted to hospital September 4, 1879, with typhoid fever, for some weeks previous suffered from headache for which she was given castor oil; diarrhoea then set in and continued. On admission her pulse was 136, respirations 30, and temperature from 101° to 105° F. She coughed a good deal.

September 10th, it was recognized that she had whooping-cough, and she was removed from the ward. September 16th, diarrhoea better; 17th, no fever; 23d, pulse stronger; slight spasm of eyelids noticed; coughed but little, but cried a good deal during the next few days. 21th, had passages containing undigested milk. 25th, a good deal of twitching of lids; eyeballs turned upward tonically; occasionally divergent strabismus; in the night slept with eyes closed. When the arms were lifted up they would remain in any position in which they were placed; when she was directed, in a loud voice, to drop the arms, she would do so slowly; her legs were in a similar condition and would remain in the position in which they were placed. The fourth finger, taken separately remained extended or flexed when placed in either posi-

tion. The arm could be partly extended or with some force flexed and remained in that position. There was some voluntary action left, for when her arms and hands were in a natural position she would attempt to take a penny from the bedclothes. Her muscular action in general was very deficient. When she was raised up in bed, her head fell forward, and when the arm was lifted vertically, it would remain in that position for minutes and then slowly come down. During the past three days she has passed a large quantity of urine with a specific gravity 1020. Extremities very cold; indifferent to everything about her, but when aroused by strong impressions the twitchings of the eyelids cease for a moment. 27th, patient a little stronger; sat up in bed; held head erect while being fed; twitching of muscles. When the extremities were placed forcibly in the cataleptic position, reduction was attended with little pain. Lower extremities less abnormal than upper ones. She could stand and walk two or three steps. Sensibility to contact, pain, and change of temperature entirely lost. A needle could be run through the skin without eliciting any evidence whatever that it produced pain; tickling the soles of the feet yielded only slight reflex movements; the patella tendon reflex was greatly diminished; her eyes were staring and her appetite was ravenous. 28th, easily awakened from sleep; one passage from bowels; answered questions; anaesthesia and analgesia persistent; conjunctiva, eyeballs and eyelashes could be touched without giving rise to twitchings; sight good. Pennies occasionally taken from bedclothes. 29th, Pulse 88; respiration 26; temperature 97° F. Less twitching of eyelids; patient appeared brighter but anaesthesia and analgesia persisted and the arms were strongly cataleptic; appetite continued ravenous; the pupils were equal and responded to light; the urine was passed in large quantity, and had a specific gravity of 1020.

30th, Pulse 81; respiration 30; temperature 99° F. Two stools; a small ulceration existing on one arm began to extend; the patient was very cross; the Schneiderian membrane was very sensitive; a slight touch produced sneezing.

October 1st, Pulse 92; respiration 22; temperature 99° F. Cataleptic position of arm sustained one minute; no twitching of eyelids; appeared brighter; when an arm was flexed a good deal of strength was required to extend it; urinated once or twice every hour.

2d, Loss of sensation complete; surface of body and extremities warmer; quantity of urine less; strength of patient increased.

3d, When an arm was extended or flexed it dropped at once. Reflex movements on pricking with needles.

4th, Anaesthesia and analgesia as before.

6th, Cataleptic position held out one minute. 7th, Slept well; passed a large quantity of urine; slight reflex movements on tickling and pricking the feet.

8th, Diarrhoea, which has existed since the 4th, less, and surface warmer; ulceration on arm looked better; Schneiderian membrane and conjunctiva gave reflex movements on tickling. 9th, Patient brighter; arm and fingers retained cataleptic position forty-five seconds and a good deal of strength was required to overcome it while it lasted; urine had a specific gravity of 1015; no albumen. 13th, Pulse regular; surface warmer; feet still cold; called for drink frequently; cataleptic condition unchanged. 14th, Sat in a rocking chair. 15th, Asked for chamber; on

<sup>1</sup> American Journal Medical Sciences, April, 1885.

tickling, no reflex; no patella reflex; cataleptic condition persisted to a slight degree; no twitching of the eyelids. After this time the general condition of the patient improved, and about October 20th, the cataleptic symptoms had entirely disappeared. She was still in bed November 5th, but sat up occasionally. Her appetite was no longer ravenous and the urine was less copious. The child recovered, but remained anæmic and weak longer than patients recovering from typhoid fever usually do.

#### FATTY DIARRHŒA.<sup>2</sup>

Tschernoff in an article on the "So-called Fatty Diarrhœa of Demme and Biedert," gives a large number of analyses of the stools of healthy and diseased infants. The fat in seven healthy children under six months old amounted to from 25 to 30 per cent. of the dried faeces. The average quantity in four dyspeptic children was 48 per cent. Two infants with erysipelas showed respectively 44 and 52 per cent. and the amount remained high long after their recovery. Two cases of catarrhal pneumonia gave 51 per cent. each, and another case 60 per cent. A child with bronchitis and nearly normal temperature showed 39 per cent.; another with chronic diarrhœa 42 per cent. A child nine months old showed during an attack of scarlatina 57 per cent., and after recovery only 32 per cent. The next case was remarkable, for the stools, which were frequent, offensive, and whitish, contained when dried no less than 75 per cent. of fatty matter; the child, aged two years, was icteric, with greatly enlarged liver and spleen. A wasted infant six months old, nursed by its mother, had diarrhœa, with shiny, blood-stained, offensive stools, which showed fifty per cent. of fat. After treatment, including the substitution of a wet nurse, the infant recovered and regained all its flesh, but the dried stools still showed 40 per cent. of fat. This case exemplified the difficulty with which children regain their power of assimilating fat. Tschernoff believes that every disturbance of the digestive tract is accompanied by increased fat in the stools, and this increase is greater still, if the temperature is raised. Even adults when feverish, show an increase of 11 per cent. The quantity of fat in the food does not seem to affect the proportion in the stools.

#### TAPE-WORM.<sup>3</sup>

At the June meeting of the District Medical Society of Hudson, N. J., Dr. S. A. Hoffer, of Hoboken, exhibited portions of a tape-worm, in all about five feet in length, removed from a nursing infant five months old.

#### DILATATION OF STOMACH.<sup>4</sup>

In an article on dilatation of the stomach in children, Dr. J. Comby, after referring to the works of Duplay, Kussmaul, Fruchner, and others, establishing as a distinct disease, primary dilatation, that is, not connected with pyloric stenosis, in the adult, speaks of how little attention has been paid to the existence of the same affection in children, although Bouchard had pointed out its relative frequency in early life, and Thibaut had written a thesis on the subject in 1882, followed in 1883 by an accurate article of Moncorso,

of Rio Janeiro, in which a careful analysis of nine cases was made, occurring in the first year of life. Comby states that since his attention has been drawn to this class of cases he has been much surprised at its frequency: he found it in artificially fed children, especially where they were rachitic, and in a large proportion of the cases the physical signs of succussion, etc., were so clearly defined that there was no difficulty in making an absolute diagnosis; he considers also that rachitis from an ætiological standpoint had nothing to do with the affection, excepting so far as the changes in nutrition following a faulty diet were concerned. The author then gives an analysis of forty cases with a record of the following especial cases:—

CASE I. Girl, two and a half months; breast-fed but incorrectly; for past eight days frequent green, foetal discharges; the mother, a strong woman of twenty-six years, with an excessive amount of rich milk, was in the habit of giving the infant the breast almost constantly; the abdomen was distended, especially in the gastric area; succussion to within a finger breadth of the umbilicus; frequent vomiting of coagulated milk. The mother was directed to nurse the infant not oftener than every three hours, and the diarrhœa disappeared without further treatment.

CASE IV. Girl, nineteen months; slight rachitis; stomach distended to umbilicus; frequent vomiting and diarrhœa; the child was still on the breast, but was fed irregularly and at night almost continuously.

CASE VI. Eleven months' infant; during early weeks of life breast fed, then sago and milk, meat soup and coffee; rachitis of high grade, great emaciation; lower margin of stomach at umbilicus.

Rachitis was only absent in five cases. In thirteen of the cases, different skin affections were present, chronic eczema in five cases, obstinate and frequently returning urticaria in two cases, and in six cases an impetiginous efflorescence on the scalp. The author states that the disease is eminently chronic in character, and the children are brought to the physician, not for their dilated stomachs but for other affections as rachitis or eczema, and it should especially be looked for where a chronic urticaria is present. The abdomen in its upper part is distended, appears broader than normal, and presents the characteristic "frog-belly." The liver, spleen and mesenteric glands are not enlarged, the distension of the abdomen being caused by the abnormally enlarged stomach. A characteristic succussion sound is heard; when this is not found below the middle of a line drawn from the margin of the ribs to the umbilicus, the dilatation is insignificant; in the higher grades the physical signs extend downward to the umbilicus. The infants have good appetites but disordered digestions, colic, foetal discharges, diarrhœa alternating with constipation, eructations are rather more frequent than vomiting. For a satisfactory physical examination only a small amount of fluid should be in the stomach, and the infant should be examined with its back on its mother's lap and with its knees raised up. The disease has no tendency to recover spontaneously so long as the nourishment is faulty and the infants desire a large amount of liquid, and the prognosis in respect to complete recovery is unpromising.

Three of the cases were under four months and the greater number were under two years, but the author thinks that quite a number of cases will be found in a later period of childhood. The treatment consists in

regulating the quality and quantity of the food and the time for administering it. The stomach pump must be reserved for the treatment of the more difficult cases.

#### ADDISON'S DISEASE.<sup>5</sup>

Professor Monti, of Vienna, reports the following case: A boy ten years of age, was strong and healthy with the exception of a slight attack of measles until the age of six; the skin was quite normal in color. In July, 1880, he fell ill without any apparent cause. He had fever with morning remissions, pain in the stomach, abdomen and head, occasional vomiting, diarrhoea alternating with constipation, and drowsiness, culminating in heavy sleeps which lasted two or three days and during which no nourishment was taken; on awaking the child was very weak and excessively emotional. At the end of fourteen days the mother noticed a peculiar yellowish-brown discoloration of the skin of the hands, and this within a few weeks spread to other parts of the body. After about five weeks the fever ceased and the digestive and nervous disturbances gradually disappeared, but the discoloration remained. In the course of the summer the child had attacks lasting two or three days, of headache, with vomiting, diarrhoea and abdominal pain. In October, 1880, the boy had another illness resembling that above described and lasting from three to six weeks, during which the brownish color became darker. The child then recovered and remained fairly well until the end of March, 1881, when the mother first noticed that the cervical glands were more or less swollen and that there was a slight swelling on one of the knuckles. During 1882 the child was much the same; the muscular system was weak, but he was able to go to school. He had two more feverish attacks, one in the spring, the other in the autumn, each lasting about four weeks. The attack re-appeared in April, 1883, and Monti first saw the case on May 10th. The child was tall, thin, and weakly built. The hair was silky, a dark blonde. The skin of the face, neck and hands were of a dark grayish-brown color, the sclerotics were a dirty white, the iris was light gray, the nails white. The skin of the thorax, back and abdomen was grayish-yellow, the lower extremities were yellowish, the buttocks and perineum darker. There were several brown spots on the ears. The mucous membrane of the mouth was pale red, that of the lips and cheeks presented several brownish-black spots arranged in groups. The tonsils were enlarged. The mucous membrane of the nose and of the prepuce was pale. The epidermis was everywhere smooth, the glands of the neck were swollen, the tongue was clean; pulse 80, respirations 24. The thorax and its organs were normal; the abdomen was prominent, palpation painful, especially so in the umbilical and ilio-cæcal regions; the liver was normal; the urine was light-yellow, acid, specific gravity of 1017, no albumen or other abnormal constituents; quantity natural. The blood was pale but there was no apparent increase of white corpuscles; the spleen was somewhat enlarged; the inguinal glands were normal; the temperature was normal. The patient appeared in a state of mild, nervous excitement, sometimes crying, sometimes laughing. Bowels regular, slept and eat well.

On June 25, 1883, the boy had one of his usual feverish attacks and was attended by Professor Monti's

assistant. He slept almost continuously the first four days and was quite undisturbed by the numerous flies which settled on his face. When roused he gave his answers slowly but correctly. The pupils were equal, reacting normally to light; there was no strabismus. On sitting up the patient swooned; the glands of the neck were more enlarged; the abdomen was retracted; both hypochondria, but especially the right were tender on pressure; the urine was normal. Within fourteen days the symptoms had subsided and the child returned to school. On May 7th, 1884, the headache, dullness and weakness reappeared and were followed in the night by excitement, delirium and occasional loss of consciousness. Soon after midnight the child became somnolent and towards morning death ensued upon an eclamptic fit. At the post-mortem examination, the dura mater was found tense, thin and hyperæmic, its inner surface shiny and smooth. The longitudinal fissure was filled with fibrinous masses; the brain substance was soft, not congested; the posterior horns of both lateral ventricles were distended with serum; the heart was flabby and of a dark-brown color; the valves were healthy; the right lung was partly solid at the apex; the liver was enlarged and softened; the spleen was enlarged; the mesenteric glands were as large as hazel-nuts; the right suprarenal capsule was completely wanting as well as the artery and vein. The left suprarenal capsule was very small; the greater part of its substance seemed to consist of rather vascular connective tissue; the kidneys were correspondingly large and somewhat softened; the bladder was normal.

#### APHASIA FROM FRIGHT.<sup>6</sup>

Dr. Denme reports the case of a child six years old where the division of the tendo Achillis for talipes equinus was undertaken without an anæsthetic. Just before the operation the child had been lively and bright, playing with her doll and talking with her mother and brother. At the moment of the division of the tendon she uttered a piercing cry, after which she completely lost all power of speech. For about ten minutes she wept silently but copiously and when she had recovered herself nothing would induce her to say a single word. This went on for eight days, during the whole of which time she was bright and lively, and answered readily by signs. On the morning of the ninth day she achieved the single word "mama," which she then used as an equivalent for everything else and repeated thirty or forty times as a long sentence, evidently under the impression that she was thereby saying everything which she wished to convey to her hearers. On the fourteenth day her vocabulary was increased by the words, "papa," "lieb," "bos," "schlafen," "trinken," which she also made do duty for all other words. On the eighteenth day she acquired a few more, and she never used one of these words in place of another on her list. She could not talk as well as usual until the twenty-first day, but after that she developed bodily and mentally in a normal manner.

—The *Prager Medicinische Wochenschrift* gives an account of a woman who carried a cotton reel in her vagina for seven years, without knowing it. The resulting inflammation had nearly occluded the canal.

## TWO CASES OF TUBERCULAR INTESTINAL UL-CERATIONS AND GENERAL TUBERCULOSIS.

IN THE SERVICE OF E. N. WHITTIER, M.D.,  
Visiting Physician, Massachusetts General Hospital.

REPORTED BY CHARLES W. TOWNSEND, M.D., Medical House Officer.

CASE I. P. C., aged forty-seven, entered the hospital, June 15th, 1885.—Mother and two sisters died of consumption. Patient's previous health excellent; occupation, night-watchman; habits good; no venereal or malarial history. For the last three years has had attacks of abdominal pain, at first at intervals of several months, but at less and less intervals lately, and for a week has had attacks nearly every day. The pain is diffuse and severe, lasts from half an hour to

present. Head not opened. Right pleural cavity contained one and one-half pints of clear serum; left pleural cavity nearly obliterated by old adhesions. A small cavity the size of a cherry-stone with ragged, cheesy walls at the apex of left lung. Both lungs oedematous and studded with numerous miliary tubercles. Pericardium contained six ounces of clear serum. Heart pale, normal. Peritoneal cavity contained one and one-half quarts of clear serum; a few old adhesions in left iliac and lumbar regions. Miliary tuberculosis of mesentery. Beginning ten feet below the stomach, twenty-seven large tubercular ulcers were to be counted in the small intestine, besides numerous small ones, one involving nearly the whole cœcum and one in the

several hours, and is generally preceded by the rumbling of intestinal gas and distension of abdomen. It is not relieved by pressure; never jaundiced; bowels inclined to constipation. Slight cough without expectoration for three years. Has lost fifteen pounds in weight in the last two months.

Physical examination: patient is pale, fairly nourished; tongue slightly coated; a few moist râles heard at left apex in front after cough; percussion note, voice sounds and respiratory murmur normal. No abdominal tenderness and nothing abnormal to be felt. Urine normal.

During the first two weeks after entrance, the patient had several attacks of abdominal pain, after which, with the exception of slight attacks in the first week of August, he was entirely free from pain. A symptom which does not appear in the history now showed itself, namely, a sensation of chilliness sometimes accompanied by slight shivering, about noon, followed by a feverish feeling in the afternoon without sweating, and by a rise of temperature, as shown by the chart, the highest evening temperature being 103.8° on the 14th of July. An hourly chart shows a gradual rise of temperature from nine in the morning, the maximum point being generally reached at four in the afternoon. Quinine had apparently no effect. For a month before death, the patient had from two to four loose, sometimes liquid dejections daily, uncontrolled by astringents and opium. At first able to walk about the hospital yard, the patient grew gradually weaker, but kept to bed for a week only before death.

August 18th, there was slight oedema of feet and legs. Moist râles as before at the left apex, and in the lower third of both lungs, front and back. Heart sound feeble, but otherwise normal; increased area of hepatic dullness and tenderness in right hypochondrium. On the day before his death, moist râles were to be heard in abundance throughout both lungs, and there was evidence of peritoneal fluid. Respirations became more rapid, pulse small, but consciousness was retained to the last, death taking place August 21st.

Autopsy, twenty-one hours after death, rigor mortis

middle of the large intestine. Liver enlarged and fatty degenerated; spleen small; kidneys and bladder normal.

CASE II. J. T., aged thirty-four, entered the hospital July 14th, 1885. Family history good. Previous health good, with exception of frequent "colds," for one of which he was in the hospital fifteen years before, the diagnosis being bronchitis. Constant slight cough for six years, with thick yellowish-white expectoration; no hæmoptysis. Feeling poorly for three months, has had five or six watery dejections daily for the last two weeks, and a constant, dull, diffuse pain in abdomen; no tenesmus; no blood or mucus in dejections; no headache, vomiting, or chills; progressive loss of flesh and strength in the last month.

Physical examination: Patient is pale, fairly nourished; tongue slightly coated; numerous moist râles heard at the left apex, both in front and behind; percussion note, respiratory murmur and voice sounds not modified at this place as compared with opposite side. Abdomen soft, not distended, slightly tender on pressure in right iliac and epigastric regions; gurgling detected. Patient was put on milk diet, with the addition later of stimulants, given opium for diarrhœa, and kept in bed. The diarrhœa continued unchecked, pain in abdomen was only occasional and slight, and emaciation rapidly showed itself. During the latter part of September, he was able to be up and about the ward part of the day, and was allowed to have soft solids besides liquids at frequent intervals, but his temperature still continued to go up to 102° or 103° at night, as shown by the chart. For three weeks before death, he frequently complained of a feeling of rawness in the back of his throat, and of the occasional regurgitation of liquids through his nose. His voice became husky. October 10th, about noon, he complained of considerable diffuse abdominal pain, his skin became cold and clammy, his temperature falling to 96.4°, pulse 120, very small and thready. Notwithstanding the use of heaters and stimulants, his temperature did not reach normal till the evening of the next day. From this time till his death, he was delirious at night;

the dejections, previously four or five daily, now increased to eight or ten, liquid, dark-colored, and very offensive. He was nearly free from pain, the frequency of the dejections being the chief complaint. Consciousness was lost during the last twenty-four hours, death taking place, October 23d.

Autopsy by Dr. R. H. Fitz, Twenty-one hours after death.

"Body much emaciated, abdomen collapsed, rigor mortis present. Dura mater showed a delicate, pale, yellowish-brown false membrane on the inner surface, with numerous patches of recent hemorrhage. Pia mater oedematous, slightly more opaque than usual, otherwise normal. Brain, nothing abnormal. Pericardium contained two ounces of pale-yellow fluid.

"Heart normal in size; right side distended with freshly clotted blood, left side comparatively empty. Two adjoining aortic valves adherent throughout nearly one-half their free edges by old adhesions; other valves normal. In the left ventricle a reddish-gray thrombus as large as a pea; another beneath the insertion of the mitral valve. Aorta, thin, narrow, and elastic, with slightly irregular distribution of lumbar arteries.

"Lungs. A few old adhesions at apex of left lung posteriorly, and at the base. In upper part of left upper lobe rather posteriorly and deep-seated, was a round nodule the size of a walnut of soft, cheesy material, enclosed within a dilated and occluded bronchus. A similar nodule, smaller in size, at the upper part of left lower lobe posteriorly, the containing wall being irregularly pigmented and puckered; surface of lung corresponding to these nodules irregularly depressed, and containing but little air. Throughout the left lung, numerous miliary tubercles, for the most part, isolated. Right pleural cavity obliterated by old adhesions. Extensive gray miliary tuberculosis throughout right lung.

"The abdominal cavity contained a quart of clear yellow fluid; the intestines firmly united to each other and to the atrophied omentum and abdominal walls by old adhesions. Surface of peritoneum studded with submiliary, translucent, gray granules.

"Spleen adherent to surroundings; increased in weight chiefly from increase in thickness. On section, surface studded with minute gray granules, and occasional large, projecting tubercles. Follicles and trabeculae rendered indistinct from delicate swelling.

"Left kidney slightly diminished in size, slightly anæmic. Right kidney showed a patch of anæmic necrosis as large as a beech-nut, slightly depressed below the surface, also diminished in size, but deeply injected. Suprarenal capsules, bladder, and testicles normal.

"Liver diminished in size, firm on section, the central parts deeply injected; occasional miliary tubercles. Tongue posteriorly and tonsillar region on both sides the seat of an extensive indurated ulcer, in the base of which numerous cheesy tubercles were to be seen. Vocal cords oedematous, and on the right posteriorly, a superficial ulcer three lines in length. Mucous membrane of stomach thickened and of a light-blue color.

"Intestines so matted together that the localization of numerous transverse ulcers with indurated base and injected margin could not be made. The ulcers showed cheesy points in the base, the induration extending nearly to the peritoneum, through which the reddened base of the ulcer appeared. Throughout the greater part of the large intestine, especially in the cæcum, extensive ulcers, resembling those previously described, occupied most of the mucous membrane, leaving occasional patches of unaltered membrane. The most extensive destruction of mucous membrane was in the cæcal region, and the peri-cæcal regions were indurated. Hæc-cæcal lymph glands cheesy and moderately enlarged.

"In the rectum, the ulcers extended to just above the third sphincter, and were associated with small, rounded ulcers, apparently of follicular origin.

"Diagnosis: Acute hemorrhagic pachymeningitis; chronic aortic endocarditis; cardiac thrombosis; chronic cheesy bronchitis and bronchial dilatation. Acute miliary tuberculosis of lungs, spleen, liver, and peritoneum. Anæmic necrosis of kidney. Chronic tubercular ulcers in intestine. Chronic catarrhal gastritis."

## Reports of Societies.

### BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

E. M. BUCKINGHAM, M.D., SECRETARY.

NOVEMBER 23d, 1885, the President, Dr. F. W. DRAVER, in the Chair.

Dr. W. C. B. FITZFIELD read a paper on

THE PRESENT SYSTEM OF APPOINTMENT OF MEDICAL EXAMINERS BY THE STATE OF MASSACHUSETTS.<sup>1</sup>

Dr. G. K. SARNE replied that it seemed to him that Dr. Fitzfield's paper is rather an attack upon the medical examiners than upon the system of their appointment. The position of medical examiner is, for many reasons,

<sup>1</sup> See page 577.

not a desirable one, and undoubtedly many hold the office simply to prevent its falling into the hands of irregular practitioners, as the office of coroner frequently did under the old system. The pay which they receive is quite inadequate to the service rendered. In the case of a view they receive five dollars, but if an inquest is held, are obliged to attend sometimes repeatedly, receiving only ordinary witness fees. In case an autopsy is made, a fee of thirty dollars is received, which at first seems quite liberal, but when it is considered that the examiner may be obliged to go many miles to consult the district attorney before the autopsy is made, and afterwards may be called upon to attend an inquest and then go before the grand jury, and day after day to attend court, all as likely as not, a long distance from home, it is readily seen that this remuneration is but slight. They are not unfrequently called upon also to pay for services which rightly belong to the State or county to pay; for instance, if it becomes necessary to exhumate a body, they are expected to pay for having the same done.

They have frequently been accused of making autopsies unnecessarily, and for this reason and in the endeavor to comply strictly with the letter of the law, no doubt many crimes go undiscovered and many criminals escape, owing to this false economy. In the instance cited by Dr. Fifield, where a dead body was found by the roadside, the examiner simply complied with the letter of the law. When the body was found, no violence was suspected. The statute under which they act is this: "Medical examiners shall make examinations as hereinafter provided; upon the view of the dead bodies of such persons only as are supposed to have come to their death by violence." As to their having much authority, they certainly have not, for the only thing possible for them to do without the consent of others, is to make a view. They cannot even make an autopsy without the authority of the district attorney, mayor, or selectmen, as the case may be.

Dr. R. H. Fritz agreed with Dr. Fifield as to the desirability of securing the services of the best men. He appreciated the difficulty of securing a large number of properly qualified examiners in the remoter parts of the State, and thought it might be of advantage to appoint a smaller number, who should exercise their office in larger sections, paying a sufficient salary to obtain a considerable part of their time. Under the existing law, he thought considerable benefit would result from the suggestion of the reader that the returns of examiners should be submitted to a properly constituted commission. The legal authorities would thus have the benefit of an early control which might prove of great service in the promotion of justice.

Dr. H. L. Bowditch said that the paper was of unusual importance. It contained statements of gross mismanagement, which he had not supposed to exist. It should not be allowed to pass without notice. He called for a committee to report on the whole subject, and the Society voted that this committee be appointed.

Dr. DRAVER (Dr. Steadman in the chair), said that if he followed inclination he would refrain from participating in the discussion, preferring that it should be carried on by members of the Society who could view the subject in a more disinterested and impersonal relation. But an intimate acquaintance with the theory and practice of the Massachusetts law concerning inquests during the past eight years, and a lively interest in all that pertains to legal medicine, seemed to place

him under some obligations to notice the position taken by the reader. He declared that he could not accept either the premises or the conclusions of Dr. Fifield with regard to the medical examiners and the method of their appointment. Nevertheless, he would not impeach Dr. Fifield's motive in introducing the subject; the rule, "Get the best," applied to the choice and commission of medical examiners as to all things where choice is possible. We all desire the best attainable excellence in government and the administration of law. We should like to have every medical examiner a man of unstained integrity, irreproachable character, exceptional powers of observation and infallible judgment. But while we are wishing for the ideal, we may properly go farther and wish for a state of society in which medical examiners will be wholly unnecessary, in which there will be no deaths by violence, no crime, no judges, juries, nor jails. Such longing for the ideal is clearly unprofitable; we must take society and human nature as they exist. The human nature of medical examiners is not unlike that of other men; not one of them claims infallibility or omniscience. But taken as a body, scattered over the State, they represent, as a rule, and with few exceptions, the best professional skill and character available. In many cases, they are the men upon whom their professional brethren have bestowed the highest medical honors. If other men, the superiors of the medical examiners, are not commissioned, it is because they have carefully kept out of sight as candidates, or have refused the position when it has been offered to them.

Dr. Fifield criticises not only the method of appointing medical examiners, but its result. It should be remembered that nominations made by the Governor are held upon the table of the Executive Council a full week, at least; they are published when they are made, and during the interval before action is taken upon their confirmation, they are freely open to criticism; they may be revoked; or, if not withdrawn, the Executive Council may reject them. Moreover, with regard to the medical examiners now in commission, having been lately re-appointed, it is well known that they were on probation and trial for fully seven years during their first term of office, and that they were candidates for re-appointment; it was not necessary that Dr. Fifield should await a public notice inviting the profession to prefer charges against the examiners, individually or collectively, for it was unquestionably the desire of the State's executive officers to secure good men for its commissions, and information concerning their qualifications is always timely.

But Dr. Fifield announces that the present method of selecting and appointing medical examiners gives us an unwholesome product, that they are a bad lot whose gross blunders do a great amount of harm; that in consequence of the errors of commission and of omission on the part of these careless and incompetent officials, men and women innocent of all crime, are now in jail suffering unmerited punishment; that by reason of the power to produce a miscarriage of justice exercised by these men, guiltless persons have been sentenced to imprisonment and to pay fines for acts which they never did. This is a serious charge. If Dr. Fifield had read the law relating to the subject, he would see that a medical examiner does not have and cannot have any such power for evil; that, on the contrary, his official acts are carefully hedged in at

every point, and if he commits an error of action or of judgment, it must inevitably be exposed and nullified, if other officials are properly alert.

The relation of a medical examiner to a case of death by violence necessarily prevents any such harmful results as Dr. Fifield has charged. In a case of death under suspicious circumstances, the examiner's sole duty is to ascertain the cause of the death. If, in his opinion, the act or the neglect of some person other than the deceased is the probable cause, as shown by the autopsy, and his conclusion is an erroneous one, that erroneous conclusion and the anatomical and other data on which it is founded, must pass successfully the critical scrutiny of the judge who holds the inquest, the judge who examines the person arrested, the district attorney, the grand jury, the counsel for the accused, the judge who presides at the trial, and the jury which renders the final verdict. If a medical examiner entertains a false view of a case, or makes an insufficient investigation before he formulates his opinion, he must be a shrewd knave and his errors must bear a close resemblance to the truth to escape unscathed and undetected these numerous examinations and cross-examinations.

It is to be observed that in all this relation to a death by crime, the medical examiner has no concern whatever with the name, identity or control of the criminal; his question is "*What* caused the death?" the question "*Who* caused the death?" must be answered by the detectives and the prosecuting officers. So that if persons innocent of crime languish in jail, the fault is clearly not with the medical examiners or the system under which they work, and it is unfair to hold them responsible for "miscarriages of justice" for which detectives, counsel, judges and juries are to blame.

But besides the scrutiny to which the work of the examiner in any given case is subjected at the hands of the judges and counsel, in the examinations and cross-examinations, a scrutiny that, if properly conducted, ought to expose all errors and incompetence on his part, there is added the critical survey which, at and before the trial, the medical expert, specially employed by the prosecution or by the defence, makes of all the medical elements in the case. It seems extraordinary that any examiner's gross blunders, such as Dr. Fifield had related, should pass the expert's inspection unchallenged, and if Dr. Fifield, as he was understood to state, had stood in all the cases cited as the special medical adviser of the district attorney, and, knowing the facts to be as he now related them, had testified in support of the prosecution, making no exposure of the medical mistakes committed, it was difficult to understand how he could escape the imputation of participating in the medical examiner's errors and their consequences.

DR. DRAPER said that he was in hearty accord with Dr. Fifield in his proposition for a central medico-legal commission, to which all autopsies by medical examiners should be submitted, and whose members would serve as medical experts in trials for homicide. Such a commission, composed of men whose reputation would give their opinions great weight, and appearing in court as independent witnesses to declare the true interpretation of the medico-legal elements of the case, would have a standing with judges and juries incomparably higher than that of the partisan, hampered and purchased expert witnesses at present in use.

Dr. Draper next called attention to the fact that, admitting the statement that objectionable and untrustworthy men sought and sometimes obtained from the State government an appointment to a position of medical examiner, the appointment was not irrevocable, and the public was under no obligation to endure an incompetent person in that commission for seven years, for the law expressly provides for the removal of any medical examiner from office "by the Governor and Council at any time for cause shown." If, therefore, the cases related are well founded in fact, there seems to be less reason for abusing the system of inquests and the method of appointing examiners than for proceeding against individual officers who have grown careless or are naturally incompetent.

As the case appears in Dr. Fifield's paper, Dr. Draper said, it may be expressed in these terms: A few errors in diagnosis have been detected in the work of some of the seventy-two medical examiners; therefore, it is time to abolish all of them and adopt another method of appointing a new set of officials. It is as if in a hospital, it had been found that one of the surgeons had made a mistake, and it should then seriously be proposed to take away the power of appointment of the physicians and surgeons of the hospital from the trustees and place it in the hands of the common council or some similar body. It is hardly fair to the many reputable men who are trying to do, and are doing, their work faithfully, to subject them to such an imputation.

Dr. Fifield's suggestion that an examination of candidates in all matters relating to medical jurisprudence would prove a successful remedy, was not, in Dr. Draper's opinion, a practicable scheme; it would be impossible to find candidates willing to submit to such a test and difficult to make a plan of examinations applicable to all parts of the State. The proposal to thrust the honor of an appointment upon physicians of the highest attainments, whether they were willing to accept it or not, would, of course, quickly end in failure.

In conclusion, Dr. Draper declared that the system which was matured eight years ago after much thought and deliberation, was proving itself on the whole the one best adapted to our needs. The method of appointment by the Governor and Council, which for many years had been found to work well in the case of all the judges of the State, may safely be trusted for inferior officers; and if, when the position of a medical examiner is vacated for any reason, the medical profession will take a little interest to see that its favors of recommendation are bestowed on its best representatives only, there will be little occasion for such a paper as the Society has just heard.

DR. J. B. AYER referred as follows to some

#### POINTS OF INTEREST CONNECTED WITH AN EPIDEMIC OF SCARLET FEVER.

In a Home in this city, where a large number of children of all ages are educated for adoption, there broke out, a year ago, an epidemic of scarlet fever, immediately following a severe epidemic of measles.

There were twenty-three cases, of which number fifteen were treated at the City Hospital. At one time forty-nine days elapsed without a case.

*Incubation.* In one case it could be proved that the disease began within forty hours of exposure, the rash appearing in less than forty-two hours. In two other

cases the period of incubation was less than ninety-six hours. I find many cases reported of one or two days' incubation, and authorities now assert that the average period of incubation is three or four days.

*Invasion.* Rash was the first symptom noticed in five cases; in the majority it appeared during the first twenty-four hours, and in all the cases inside of forty-eight hours. In one case, exudative pharyngitis was the first symptom.

*Desquamation.* In three cases there was none. The average period of the beginning of desquamation was the tenth or eleventh day. In one case there was a possibility of its having been delayed till the end of the third week.

Not long ago a physician to a private school in England was censured by many because he allowed a pupil to return to his home twenty-one days after the first appearance of scarlet fever, no desquamation occurring up to that time. It was claimed that desquamation appeared at a later date.

If I had a similar case, I should make an *arbitrary rule of waiting three weeks after the disappearance of the rash* before dismissing my patient.

*Duration of desquamation* was very variable. The average period of illness of those who desquamated and were discharged well was thirty-nine days.

In one case I kept a child isolated sixty-nine days, and then discharged him, although there was a little *brun* still visible on the soles of the feet.

*The Medical Press and Circular* (January 21, 1885), states that the Mousal Fever Hospital of Manchester, Eng., has been in the habit of sending its scarlet fever patients to an Infirmary at Pendlebury for treatment, paying a fixed sum annually and a stipulated sum weekly for each patient. The Manchester authorities rebelled because some of the cases were kept fourteen weeks and the majority over six weeks. The Infirmary, however, claimed that it could be proved that scarlet fever had been carried as a result of their former practice of discharging patients at the arbitrary period of six weeks.

*Exudative Pharyngitis and Tonsillitis.* Ten cases of all degrees of malignancy were noticed during the epidemic. The question suggested itself whether or no some of these cases were not examples of scarlet fever without skin symptoms.

One fatal case of nephritis was probably a case of *scarlet fever without eruption*, or if there was an eruption, it could not have lasted many hours (perhaps coming and going in a single night). In this case *œdema* was the first symptom. On close examination a roughness of the palms of the hands was noted, but I could not identify it as a scarlatinal desquamation.

*Important Sequela* were absent, but there followed twenty-five cases of *roseola*. Fourteen of these children had recently been treated for measles or scarlet fever.

To a question by Dr. Rotch, Dr. Ayer answered that only three patients had vomiting of any importance.

Dr. S. L. Abbott asked if known facts warranted a physician in fixing definitely the period at which it was safe to allow a patient that had had scarlet fever to come into close relations with persons who had not. Physicians were constantly asked this question and he had found it a very difficult one to answer. In illustration of this he mentioned the following case in his experience.

In a family which he had attended professionally

during their winter residence in the city, while passing the summer in the country, the oldest boy was taken sick with scarlet fever. The youngest child was immediately sent to Boston, and the parents, with the second son, took rooms on the lower story of their country residence, leaving the sick boy on the second story in charge of the grandmother and a nurse. The season favored the freest ventilation and the patient went through a pretty severe attack of scarlet fever, under the care of a skilful physician in the neighborhood, and recovered. During this time there was not absolute non-intercourse between the parents and those attending upon the patient, but pains were taken to avoid being with them more than a few minutes at a time. The second boy escaped the disease during the sickness of his brother. The latter being entirely well, was taken by his grandmother, at the end of the fifth week, to the seashore, where they remained a week. During their absence the room which they had occupied during his sickness was thoroughly renovated, and the clothing worn by the patient during his illness was burned. All the woodwork of the chamber and the closets opening into it, were thoroughly scoured and newly painted. The walls were newly papered and the ceiling whitened, a new carpet was laid on the floor, and all the furniture which was cushioned, as well as the mattresses and blankets, were soaked in naphtha. In each room on the second story, three pounds and a half of sulphur was burned, the windows and doors being closed, the closet doors opening into them being left open. The sulphur fumes were allowed to remain in the apartments undisturbed for six hours.

At the end of the sixth week the family returned to their rooms upstairs, the boy came home from the seashore and saw his brother for the first time. At just one week from that date the second boy was taken sick with scarlet fever. It would seem that little more could have been done to disinfect the house short of burning it down, and the convalescence of the first patient seemed to be complete before he left home. As to whether there was any desquamation going on at the time of his return, Dr. Abbott was unable to say, as he did not have an opportunity to examine the child.

Dr. T. M. Rotch remarked that it had been noticed that where a child with scarlet fever was placed in one of the upper rooms of the house, other children of the household were not so apt to be infected as when a lower room was occupied. He also said that where equally thorough precautions were taken to disinfect the patient and the room, exposure of other children to the patient was less liable to be followed by infection, than exposure in the room where this same patient had been ill.

Dr. Rotch also observed that the number of cases where marked vomiting had occurred in the prodromal stage in Dr. Ayer's report, was unusually small.

#### PATHOLOGICAL SOCIETY OF PHILADELPHIA.

W. E. HUGHES, M.D., RECORDER.

MEETING November 12, 1885.

The President, J. C. WILSON, M.D., in the chair.

Dr. FESSLELL presented specimens from a case of mastoid disease. Male, aged twenty-five years. Never had scarlet fever. Since vaccination at the age of five years has had occasional attacks of suppuration of the middle ear. General health was good. Was first seen

by Dr. Fussell, July 14th; for several weeks he had had earache with one slight chill. When seen, hearing was very poor, membranes tympanic, opaque, swelling and redness over left mastoid process and temperature elevated. His general condition grew worse, and an incision was made over the mastoid process, but it failed to find pus. On extending this incision, a few days afterwards, pus flowed freely and he was much relieved. He afterward grew worse, fell into a typhoid condition, and died July 24th. Before death blood oozed freely from the cutaneous surface. At the autopsy the mastoid cells were found filled with pus, in the inner half of the process was a large irregular cavity filled with a pulsatous mass of necrosed bone; this communicated with the middle ear. The walls of the lateral sinus were thickened, easily detached from the bone, and the seat of a purulent inflammation. The sinus contained no thrombus. The meninges over this spot was discolored though not inflamed, but there was a patch of inflammation over the anterior edge of the left lobe of the cerebellum. Brain substance was normal. Remaining organs were not remarkable, except the right lung, which contained in its apex two small abscesses. From the condition of the sinus the reporter thought there had been an actual admixture of pus with the blood.

DR. PACKARD presented an anomalous lung. It was taken from the body of a negro who died of Bright's disease. From the inferior surface of the lower lobe of the right lung springs a tongue-shaped process of pigmented, crepitant lung disease, two and a half inches long and two inches wide at its base, resting upon the diaphragm, its upper surface being in apposition with the under surface of the lower lobe. Dr. Packard had recently seen in the body of another negro a similar anomaly, except that the process was smaller and situated more anteriorly.

DR. MUSSER presented a cystic kidney. It was the right kidney, and was taken from the body of a man, aged seventy-two years, who died of apoplexy. The kidney was cirrhotic and contained two cysts, the larger occupying the upper one-fourth of the organ. Its walls were firm and it contained clear fluid in which floated cheesy masses, which the reporter thought were degenerated pus. When first seen the patient was passing small quantities of bloody, highly albuminous urine, and complained of pain in the right renal region. These symptoms were apparently due to an acute process grafted upon the chronic lesion. The blood and most of the albumin disappeared, but the pain persisted. Was this pain due to the cyst?

Also, specimens from a case of diabetes mellitus. Female, aged forty-three years. Had a vesico-vaginal fistula fourteen years. Diabetes had existed, without apparent cause, two months. Patient was unusually fat and had lost no weight. She died of coma. Temperature in the abdominal cavity, three hours after death, was 107.8° F. Liver large and fatty; gall-bladder contained thirty stones; kidneys fatty; pancreas normal; blood had a most marked lactescent appearance, and after standing twelve hours globules of fat collected on its surface; lacteals in the mesentery engorged with chyle. Microscopic examination of lungs showed no fat emboli. In the urinary bladder was a large phosphatic calculus.

DR. OSLER thought the peculiar condition of the blood was what we should find normally in a person dying during digestion, and called attention to the fact

that very frequently in diabetes there is the engorgement of the lacteals.

Also, a fetus papyraceus. The mother was delivered in the morning of a mature living child, and in the evening of this fetus. It is apparently of the fifth month of pregnancy, and with the exception of shrivelling and paling of the skin, is quite normal. The cord is thin and soft, its length unknown. The placenta is thin, flat, compact and whitish-yellow, apparently having undergone complete fatty degeneration.

DR. J. B. ROBERTS presented a small tumor, the size of a hickory-nut, which he had removed from the back of the wrist of a young man. It had the clinical appearance of an ordinary ganglion, but attempted evacuation showed it to be solid. It was then enucleated and found to have been developed within the theca of the tendon going to the middle finger, and probably between its fibres. The great rarity of solid tumors in this locality was mentioned.

DR. HUGHES presented a primary carcinoma of the liver. Female, aged fifty-eight years. A daughter died of cancer of the uterus. She had been in good health till eighteen months ago, when flesh and strength began to fail. With this there were occasional attacks lasting about a week, of headache and sick stomach, followed by diarrhoea. There were pretty constant lancinating pain in the hepatic region. Five months ago she had an attack of jaundice (her only attack) lasting two weeks. And at this time a tumor was detected in the liver. At the autopsy the liver was found much enlarged, and scattered through its substance were firm cancerous nodules, varying in size from an orange to a pin-head. In addition to these there were several cysts, one in the left lobe two inches in diameter, filled with clear fluid. The liver substance between the cancerous nodules was normal. The gall bladder was full of healthy bile and the ducts patulous. There were no enlarged glands in the fissure of the liver, but the retro-peritoneal and mediastinal glands were increased somewhat in size, and the seats of secondary deposits. With these exceptions there was no growth outside the liver. The intestines were crowded into the left side of the abdomen by the enlarged liver. The stomach was very small, only one inch in diameter at its fundus. There was an intussusception three inches in length, at the ileo-cæcal valve, which on being reduced, which was affected with some difficulty, showed the apposed surfaces of peritoneum covered with lymph.

DR. FORMAN presented specimens and read a paper on

#### AN ANALYSIS OF TWO HUNDRED AND FIFTY AUTOPSIES ON DRUNKARDS, ILLUSTRATING THE MOST PROMINENT ANATOMICAL LESIONS OF CHRONIC ALCOHOLISM.

He considered the most conspicuous lesions to be cyanotic induration of the kidneys, fatty infiltration of the liver, and mammillated stomach. His cases had been those in which there had been a history of a long-continued series of debauches, the subjects often dying in one of these debauches, and did not include moderate drinkers or those who perished after imbibition of an enormous quantity of alcohol without any previous chronic excesses. He thought that the exposure, irregularities of diet, etc., incident to a state of drunkenness had much, probably more, than the alcohol itself, to do with the productions of the lesions, but it was

not at all possible to separate one from the other. He gave a long list of lesions considered by various authors to be results of chronic alcoholism, among which the cirrhotic liver, with contraction, held a prominent place. He had himself at one time considered cirrhosis, a very frequent, if not almost necessary, concomitant of long-continued, excessive use of alcohol, and had even testified in court that a certain person was not likely to have been a hard drinker because at the autopsy no cirrhosis of the liver was found. He had thought, too, that the connection between the two was so close that it was impossible to have a case of cirrhosis without a previous history of alcoholism, as is held by various authors. Therefore, it was surprising to him to meet in his two hundred and fifty autopsies, with only six cases of cirrhosis of the liver with contraction. In two hundred and twenty cases the liver was considerably or even very much enlarged, the enlargement in most cases proving to be due to a fatty infiltration. Cyanotic induration of the kidney and chronic gastritis with mammillation of the stomach were found in nearly every case. This cyanotic induration is peculiar and differs from the cyanotic induration due to heart disease. At a future meeting he will give a detailed account of the above lesions and a more extensive analysis of the cases.

Dr. TYSON could not speak from a systematic observation of a large number of autopsies in the cases of confirmed drinkers, but he remembered distinctly being surprised in several cases by the absence of cirrhosis where he confidently expected to find it.

Dr. WILSON said that Anstie, in the article on Alcoholism in Reynolds's System of Medicine, had called attention to the comparative infrequency of contracted liver in confirmed drinkers. This observer, in an extensive out-patient practice in London, had seen large numbers of cases of alcoholism, but very few among them presented the physical signs of cirrhotic (contracted) liver. The experience of the staff at Blockley Hospital sustains this view. There many of the patients are soaked with alcohol, but even among those whose death is directly or indirectly due to alcoholic excess, fatty liver is much more common than contracted liver.

Dr. OSLER thought the experience of pathologists and morbid anatomists with histories of patients is not of the most satisfactory character, he often having had cases to dissect where he knew very little of the history. Before saying these cases were chronic alcoholics, Dr. Formad present more specific statements about them. His own experience with livers in a large number of autopsies on cases of chronic alcoholism had led him to divide them into four classes: 1. Those in which the condition of the liver is pretty satisfactory; some of these cases may take alcohol for many years and yet the liver pass muster. 2. Fatty cirrhotic livers, the cirrhosis may not, perhaps, be distinct to the naked eye but plainly shown by the microscope; this is the largest class. 3. Hobnail livers; these he would say were much more common than in Dr. Formad's series. 4. Hypertrophic cirrhotic livers. The difference between his observations and those of Dr. Formad might possibly be accounted for by a difference in the form of alcoholic beverage taken. He had not observed the special form of kidney described by Dr. Formad. In reply to a question, he said, in order of frequency he would place them, fatty cirrhotic, hobnail, hypertrophic cirrhotic, apparently normal.

Dr. S. SOLIS-COHEN said, there were certain theoretical considerations which suggested themselves in this connection. The text-books teach that the lesions of alcohol are of two kinds, sclerosis and steatosis. It is known that in some organs the fibrous change precedes the fatty one. The latter is the higher grade of degeneration. The subjects of Dr. Formad's autopsies were confirmed whiskey soakers, in whom one would expect to find more intensity of degenerations than in those whose use of alcohol, though persistent and excessive, was not so outrageous. Another point which has not been alluded to, was the fact that some lesions might result from a local action of the poison upon the tissues, while others might be due to its systemic action. No study of the subject could be complete in which these points were overlooked.

Dr. RANDALL suggested that the point touched upon by Dr. Osler, the character of alcoholic beverage, might be very important. In Vienna, among beer-drinkers, he had found the fatty liver much more common than the cirrhotic, while in England where much gin is drunk, and he should suppose in Scandinavian countries, where they drink altogether strong spirits, the cirrhotic liver is doubtless comparatively frequent.

Dr. MÜSSEN had recently had to go over the records of the Pathological Society, especially in liver diseases, and had found the total experience of different observers the same as Dr. Formad's, and also in those cases cirrhosis was caused not so much by heavy drinking, as persistent drinking of spirit, and on an empty stomach.

Dr. FORMAD presented the sac of an Extra-uterine Pregnancy. The woman from whom this was removed, had not suspected that she was pregnant. She was in perfect health till twelve hours before death, when she was suddenly seized with excruciating pain in the left groin, rapidly followed by collapse. On opening the abdomen it was found to contain at least a gallon of partly clotted blood. About the middle of the left fallopian tube was the sac with a rent in its posterior wall. This sac was one inch in diameter, and contained clotted blood and placenta tissue. The uterus was twice its normal size. The foetus was not found.

Also, an aneurism of the ascending aorta rupturing into the pericardium. The patient was a laboring man, and had considered himself in perfect health. He died very suddenly. The aneurism, one-half inch in diameter, was situated just above the posterior aortic leaflet, and had broken through the wall of the aorta, at the point where it touches the descending cava. The cavity of the pericardium was fully distended with clotted blood.

#### NEW YORK NEUROLOGICAL SOCIETY.

STATED meeting, November 3d, 1885.

The President, W. R. BIRDSALL, M.D., in the chair. Dr. LEONARD WEBER read a paper entitled

#### A CONTRIBUTION TO THE STUDY OF LANDRY'S ASCENDING PARALYSIS.

It was in 1859 that Landry described a few cases of ascending paraplegia with negative post-mortem results as regarded the spinal cord, to which he gave the name of "paralyse ascendante aigue," and in the same year Kussmaul reported two rapidly fatal cases of spinal paralysis, in which the post-mortem appearance of the

cord was apparently normal. The attempt of Petitfils to classify Landry's ascending paralysis among the varieties of poliomyelitis anterior acuta or subacuta has been repeated quite recently by Professor Immermann, but in the light of later researches and of the negative results of autopsies made by Westphal, his theory is hardly tenable. Another and perhaps less objectionable theory is that of Rogers, who believes that many cases of the favorable form of Landry's paralysis are really polynneuritis acuta, of infectious or other origin, in which the spinal cord is either not at all or only secondarily affected. In an article in *L'encephale*, No. 2, 1885, this writer instances the clinical picture presented in many affections of the spinal nerves, particularly in polynneuritis, in which the symptoms are very similar to those of disease of the medulla spinalis, in cases of simultaneous peripheral and spinal affection a correct diagnosis is of course difficult, but although we have hitherto, says Rogers, paid almost exclusive attention to the central lesions, the course of the disease often bears evidence of the fact that the lesion ascended from the periphery to the centre, and he claims that not only do many cases of Landry's paralysis belong in the category of peripheral nervous affections, but also Duchenne's "paralysie générale spinale subaigue," and "paralysie diffuse."

Dr. Weber then gave Roger's description of the usual course of the disease, and said regarding the etiology that we were still in the dark; Westphal laid much stress upon infection, and Roger drew attention to the frequent coincidence of polynneuritis and tuberculosis. Erb said as late as 1879 that cases of progressive polynneuritis ought not to be mistaken for acute ascending paralysis, since the differential diagnosis was sufficiently established by the sharp pains, anaesthesia and paralysis limited to the affected nerves, and their rapid loss of electrical excitability.

On the strength of these recent observations he thought it might be justifiable to speak of two forms of acute ascending paralysis, the well characterized spinal and the less well known peripheral. Acute ascending spinal paralysis is characterized clinically by motor paralysis, beginning usually in the lower extremities and advancing with some rapidity to the trunk and upper extremities. The bladder and rectum are but little affected; sensation is nearly normal, and the affected muscles do not waste much, nor suffer any change in their electrical excitability. More or less fever may be present, and death from asphyxia is a not very unusual termination. No cord lesions are found at the autopsy. Landry's paralysis is more common in men than in women, and occurs with greatest frequency between the ages of twenty and forty years. It is thought by Landry, Westphal, Roger and others, that infection, of an unknown character as yet, may be the real determining cause of the disease, and it is significant to note that in some carefully made autopsies changes similar to those occurring in other infectious diseases have been found in the liver, spleen, lymphatic glands and intestinal follicles. In the fatal cases death may occur at a period of the disease varying from two or three days to three or four weeks, but the average duration seems to be from eight to twelve days. When recovery ensues, improvement begins usually within a few days after the disease has been fully developed, restoration occurring first in the parts last affected, and progressing very slowly.

Some cases of poliomyelitis anterior subacuta simu-

late very closely acute ascending paralysis, and it may not be until the development of atrophy and the loss of electrical excitability that we can be certain of the presence of anatomical lesions in the spinal cord. But a well-marked case of poliomyelitis anterior acuta is not progressive, does not attack the medulla oblongata nor lead directly to a fatal termination; the loss of faradic excitability and the muscular atrophy develop rapidly. In very light cases a doubt might arise in diagnosis. In acute central and infectious myelitis we always find fever, marked sensory disturbances, early loss of all the reflexes, paralysis of the sphincter, diminished faradic excitability, bed-sores, and a rapidly fatal termination. Certain forms of spinal syphilis resemble closely Landry's paralysis, and the diagnosis can often be determined only by the history of the case and the positive results of specific treatment. The prognosis of acute ascending paralysis is always serious, as it is impossible to tell at the beginning whether a case will result in recovery or death. Antisyphilitic treatment has given doubtful results, but better have been obtained from the wet pack or warm bath followed by cold affusions. Of remedies, the best would seem to be iodide of potassium and ergot. The application of a continuous current along the spine is recommended by Erb.

The author then related the following case which had been observed by himself: On December 20, 1880, he was called to see J. H., a butcher, thirty-one years of age, of apparently good constitution, no hereditary taint; syphilis denied. In early life, he suffered often from intermittent fever. At the age of twenty-one, he went to work in a barometer factory, and after some time, began to grow weak, had occasional slight tremor and frequent vertigo, but no salivation or other sign of mercurial poisoning. These troubles increased, so that he was compelled to give up this work after four years. He then spent four years in the West, and returned home in good health two years ago. About three weeks before he was seen by Dr. Weber, the patient's horse ran away with him in his open cart, and he was obliged to exert all of his strength to control the animal. He received no apparent injury or concussion, but felt tired and ill all the afternoon. The next day he kept about with difficulty, and the day following felt somewhat ill and had slight fever; and, after some days of parasthetic feelings, such as numbness and tingling creeping up from the fingers, he gradually lost the use of both arms, and two weeks later, after similar sensations proceeding from the toes upward, the lower extremities became also paralytic. No paresis of the sphincters was noticed then or at any subsequent time. The stools were retarded. The intercostals and other muscles of the trunk remained intact, and there were no symptoms indicating involvement of the medulla oblongata, but the patient felt some pain along the spine, and continued to have pain and numbness here and there in the extremities. Up to the time of Dr. Weber's visit, the case had not been examined with special care. The author found the patient still unable to do more than move his limbs slightly while in bed; he could neither stand nor walk, nor had he the power to grasp firmly any object. Cutaneous sensation appeared to be normal, but the patellar and achilles tendon reflexes were absent. The limbs were not wasted, and the muscles responded to electrical stimulus. Pulse and temperature were normal, and examination of the urine gave negative results. The slight improvement

of the paralysis, noticeable to the patient, at the beginning of the fourth week, had not progressed any further. Ascending myelitis and poliomyelitis were excluded, and the diagnosis made of ascending paralysis, Landry's. It being impossible to carry out at his home, a systematic course of electrical treatment, with massage and warm baths, which seemed to be indicated, the patient was removed to Roosevelt Hospital, where the late Dr. Goetky became interested in the case. He agreed with Dr. Weber as to the probable nature of the disease, and also looked upon the chances of recovery as good. The patient was discharged cured on the thirtieth day, and was soon able to resume his occupation. He called at Dr. Weber's office, October 30th, 1885, at which time he appeared in fair health, could walk briskly and firmly, and said he was well able to attend to his business, but he required more sleep than he did five or six years ago. He had occasional backache, but no lacerating pains. The bowels were somewhat constipated; the urine normal; the patellar tendon reflex was totally abolished on both sides, and the patient could not stand very well on one foot when the eyes were closed. The pupils were normal. There were no sensory disturbances and no parasthesia.

The author then related briefly two cases recently reported by Sörgenfrey and H. Mietz, in which there was early loss of the patellar and achilles tendon reflexes, but in which, as opposed to his own case, the reflexes returned after the complete recovery of the patients. He also mentioned a case of Immermann's, in which the diagnosis wavered between anterior poliomyelitis and Landry's paralysis, and in which, at the autopsy, there was found recent inflammation of the anterior horns of the cervical, dorsal, and lumbar regions of the cord. It was this case which lead Immermann to conclude with Pettit that both these clinical pictures might be due to the same morbid process, differing only in degree.

#### DISCUSSION.

DR. E. C. SEGUN had not seen a case of Landry's disease, but he had always had a strong suspicion that there was a great similarity, if not identity, between that disease and poliomyelitis acuta. The mere matter of ascension did not seem to him to be of so great importance in the diagnosis. The views which, when a pupil, he had heard Brown-Sequard frequently express with regard to ascension of spinal symptoms, had always seemed to him very reasonable. They were that ascension of symptoms might be apparent when they did not represent any ascending lesion in the cord; they were due to a change in the depth of the lesion in the cord. Suppose theoretically, a case of paralysis of the arms, with later paralysis of the legs; it is not at all necessary to suppose a descending lesion in order to explain the descending symptoms; a change in the depth of a lesion which extends but a little way up and down the cord will account for the descent of the symptoms. In the same way, we could account for ascending symptoms without supposing an ascending lesion in the cord. Many authors laid stress upon the value of negative symptoms in the diagnosis of Landry's paralysis, such as absence of degenerative reaction and muscular atrophy; but it was equally true that in many cases of poliomyelitis these symptoms were retarded. He regarded Immermann's case as instructive, inasmuch as it showed the similarity, if not the identity of the two diseases; the difference might be in exact location or in the virulence of the affection.

DR. PECKHAM described the symptoms in the case of a girl sixteen years of age, whom he saw only once and made a diagnosis of acute poliomyelitis, following exposure by sitting on a rock at a picnic. He gave a favorable prognosis. The case was reported by Dr. Rockwell before the American Neurological Society in June last, as one of transverse myelitis with recovery. Considerable discussion followed with regard to the nature of the disease.

DR. SACHS thought that while Immermann might entertain the idea that the pathological process in Landry's disease and poliomyelitis was the same, he did not suppose that he believed the lesions to be identical in localization. While the question of infectious origin had not been demonstrated in either acute myelitis or Landry's disease, Dr. Sachs thought it deserved investigation.

DR. WEBER closed the discussion, reviewing the differential diagnosis between Landry's paralysis and poliomyelitis anterior acuta.

#### THIRTEENTH ANNUAL SESSION OF THE AMERICAN PUBLIC HEALTH ASSOCIATION, DECEMBER 8th, 9th, 10th, 11th.

THE Thirteenth Annual Session of the American Public Health Association, was held at Willard Hall, Washington, D.C., beginning at ten o'clock on Tuesday morning, the President, Dr. James E. Reeves, presiding. The following members and delegates from Massachusetts were present during the week: Messrs. John Fallon, C. E. Denny and Dr. S. W. Abbott, as delegates of the State Board of Health, Lunacy, and Charity, and also as representatives of local Boards of Health; Drs. H. P. Walcott and A. F. Holt, of Cambridge; Dargin, of Boston; Rice, of Springfield; Jones, of Taunton; Adams, of Pittsfield; Mayor O'Connor, of Holyoke, and also Dr. B. F. Davenport, of Boston, and Dr. D. A. Sargent, of Harvard University.

After the disposal of the usual routine business, including the reports of officers, the morning session of the first day was devoted to the following papers:

#### SANITARY AND STATISTICAL NOMENCLATURE.

By DR. E. M. HUNT, of Trenton, N. J., Secretary of State Board of Health.

#### FORMS OF TABLES FOR VITAL STATISTICS.

By DR. J. S. BILLINGS, U. S. A.

Dr. Billings discussed the forms of statistical tables now in use by Boards of Health and Registration, and stated his opinion as to what should be included and what rejected from such tables. Diagrams of charts were especially commended as important adjuncts of such work.

DR. HENRY B. BAKER, of Lansing, Michigan, Secretary of State Board of Health, gave a paper on the RELATION OF RAINFALL AND WATER-SUPPLY TO CHOLERA.

A similar line of observation was illustrated in this paper with that which Dr. Baker has for several years carefully carried out with regard to typhoid fever, showing its close relation to the depth of water in the soil. Charts were shown illustrating the subject.

#### THE VIRUS OF HOG-CHOLERA

was presented by DR. D. E. SALMON, of Washington.

This disease was shown to have been unusually prevalent during the year, so much so, as to have cost the country nearly \$30,000,000. The improper disposal of hogs which had died of the disease, both as food and otherwise, was severely criticised.

The Treasurer, Dr. Lindsley, reported the receipts of the Association as \$3,338, and expenses as \$2,233 for the year, leaving a balance of \$1,105.

The Committee on Disinfectants reported in print, its reports having been published in portions in the medical journals during the past year. At the evening session, the time was devoted chiefly to addresses of welcome by Dr. J. M. Toner, of Washington, and Hon. J. B. Edmonds, of the Board of Commissioners of the District. A letter of welcome was also read from President Cleveland.

Dr. JAMES E. REEVES, President of the Association, delivered the annual address, treating mainly upon matters pertaining to public sanitation, and especially upon the importance of National aid in the establishment of a biological laboratory for the study of infectious diseases.

#### SECOND DAY.

The first paper presented on Wednesday was read by Dr. P. H. BOYCE, Secretary of the Provincial Board of Health, of Ontario, and entitled

#### SMALL-POX IN CANADA, AND THE METHODS OF DEALING WITH IT IN THE DIFFERENT PROVINCES.

An account of the epidemic was given from its origin in the early spring to the present time, during which period about 3,100 deaths had occurred. The regulations adopted by the Ontario Board and the means taken to prevent the spread of the epidemic were fully detailed. He was followed by Dr. Kingston of Montreal, who gave in detail an account of the epidemic of the past season. Both he and Dr. O'Connor also gave testimony to the fact already alluded to in the JOURNAL that the Canadians are not a filthy people, and the epidemic was due mainly to the neglect of vaccination.

#### IMPURE AIR, AND UNHEALTHY OCCUPATIONS AS PRE- DISPOSING CAUSES OF PULMONARY CONSUMPTION.

was the title of a carefully prepared paper by Dr. C. W. CHANCELLOR, Secretary of the State Board of Health of Maryland. General statistics relative to consumption were first given, followed by reference to the effect of improper ventilation, crowded workshops, small rooms, and occupations in which workmen were exposed to irritating dust.

#### AFTERNOON SESSION.

At the afternoon session, the committee on State Boards of Health submitted the following resolutions:

FIRST. That it is the judgment of your committee that in carrying out the object of their creation it is necessary to have a conference of delegates from State Boards of Health at least once a year for the purpose of consultation and to promote unity of action on matters essential to public health, the prevention of epidemics and the most efficient means of instructing the people in sanitation.

SECOND. Your committee would suggest that the most suitable occasion for holding this conference would be during the annual meeting of the American Public Health Association, and that our president and secretary arrange the time of the meeting in connection with the executive committee of the American Public Health Association so as best to promote the interests of the association and the conference.

THIRD. Any conclusions of this conference that are of interest to the public shall be reported by the secretary to the American Public Health Association through the standing committee on State Boards of Health.

(To be continued.)

#### THE NEW YORK ACADEMY OF MEDICINE.

STATED meeting, November 19, 1885.

#### A SECTION OF RHINOLOGY AND LARYNGOLOGY TO BE ORGANIZED.

THE SECRETARY read an application from a number of Fellows for the formation of a section in Rhinology and Laryngology, and on motion it was voted that such a section should be established.

#### THE REDUCTION IN THE APPROPRIATION FOR THE BOARD OF HEALTH FOR THE YEAR 1886.

The Secretary read a letter to the President of the Academy from James Gallatin, Esq., in which he stated that he had petitioned the Board of Estimate and Apportionment of the city for a reduction in the appropriation for the Board of Health for the coming year, on the ground that the finances of the latter could be more economically managed without in any manner impairing its efficiency from a sanitary point of view. The Board of Health had asked for an appropriation of \$245,166, an increase of over \$39,000 beyond that of the present year, and the Board of Estimate and Apportionment had now decided that the appropriation should be cut down to \$170,000. Mr. Gallatin went on to say that he had addressed this letter to the President of the Academy of Medicine in order that his motives should not be misunderstood in the position which he had taken. He was fully aware to how large an extent the efficiency of the Board of Health depended on the medical element represented in its constitution, and, trusting that the reduction of expenses referred to would not be made the pretext for dismissing or cutting down the salaries of the able physicians connected with it, he ventured to hope that the Academy would not hesitate to give an expression of its opinion on the subject. Coming from a source like this, he felt sure that such an expression of sentiment would have great weight with the authorities.

On motion of Dr. Gouverneur M. Smith, a preamble and resolution were unanimously adopted to the effect that, whereas it was a generally recognized fact that the efficiency of the Board of Health depended on its medical representatives, and whereas, it had been decided by the authorities that some reduction should be made in the annual appropriation for the expenses of the Board, it was therefore resolved that the Academy of Medicine should respectfully urge that this reduction should be made in such a way that none of the competent medical men now on its service should be discharged or should have their salaries so reduced as not to afford a fair compensation for their faithful and efficient labor.

Dr. HENRY D. NOYES then delivered

#### THE ANNIVERSARY DISCOURSE

before the Academy, the subject of which was, "Path-finding in Medicine." In opening, he offered the hearty congratulations of the Academy, as well as his own, to their distinguished colleague, Professor Janeway, who was to have delivered the address, on his recovery from a recent very severe illness, which had prevented him from preparing it. During the past year, he said, he had had the opportunity of becoming personally familiar with much of the scientific work which was at present being done in Europe, and he had especially profited by the proceedings of the great International Medical Congress at Copenhagen, and

the subsequent Ophthalmological Congress at Heidelberg. From what he had observed, it was his conviction that progress was now to be made in the line of acute, deep, and accurate research. Great triumphs have been won through the agency of scientific physiological and pathological investigation, and clinical observation must now be supplemented by the laboratory. Referring to the achievements of American medical men, he said the wonder was that they had accomplished so much with the meagre facilities at their command. Collective investigation was admirable in its way, but after all it was merely clinical knowledge, and at the present day we could not rest with clinical observation.

The microscope, he went on to say, was the great agency by which the brilliant results of modern pathology had been obtained, and though the title of his essay might at first seem somewhat grotesque, he thought it was not inappropriate when we considered how many paths through the formerly hopeless jungles of the mysterious human economy this instrument had assisted in opening up. Proceeding to illustrate his subject, he spoke particularly of the results accomplished in pathological research by such men as Virchow, Fleming, and Pasteur. When speaking of microorganisms and the wonderful era in scientific medicine which the discovery of their importance had inaugurated, he mentioned that Rosenbach in 1884 said that he knew of no less than six distinct microbes which were capable of exciting suppurative in the human body. Having spoken of the triumphs of antiseptic surgery, and the great advances which had recently been made in our knowledge of the physiology of the brain, he gave sketches of the careers of the distinguished Dr. Thomas Young, in whose time nothing was esteemed in medicine which was not of a directly practical nature, Edward Palmer, the wonderful linguist, Heinholtz, the inventor of the ophthalmoscope, and of Graefe and Donders, the great ophthalmologists.

Turning again to America, he spoke of the great disadvantages under which our men suffered from lack of facilities. Yet a great deal had been accomplished by individual effort, and the reputation of many of our surgeons, especially those who had distinguished themselves in the field of gynecology, was world-wide. No more brilliant instance of a noble and distinguished career, in the face of almost insuperable difficulties, could be mentioned than that of the lamented Marion Sims.

The investigation of disease was to be prosecuted in two lines: *first*, the bedside study, and, *second*, what might be termed the philosophical study of diseases. The problem was to unite these two, so that they might go hand in hand; and to-night his plea was for the laboratory.

The need of the American profession was urgent; but at length the people seemed to be beginning to appreciate to some extent the exigencies of the situation. Having referred to the liberal gifts of Mr. Carnegie and Mr. Vanderbilt to two of the medical colleges, which he said are most timely and hopeful, he spoke of the need of something more—such as institutions in the line of the Johns Hopkins University, of Baltimore—which would be suitably equipped and offer facilities, not merely for teaching students, but for instructing teachers and for the prosecution of the most profound original research. There was no trouble in

getting wealthy people to give liberally for the support of hospitals, dispensaries, and other charitable institutions for the sick; but they should be made to understand that their charity was not complete unless it was in part, at least, devoted to enabling the physician to treat the sick more successfully.

DR. FORDYCE BARKER, in moving a vote of thanks to the orator of the evening for his able, interesting, and suggestive address, said that an annual oration had constituted one of the features of the Academy of Medicine from the time of its organization until within a comparatively recent period, when the custom had fallen into disuse. He well remembered the first address of this kind, which was delivered, in 1847, in the old Tabernacle, on lower Broadway, near the former site of the New York Hospital, by the late distinguished Dr. Francis, before not only the Fellows of the Academy, but a crowded audience of ladies and gentlemen. At that time he was not himself a resident of the city, but he was present on this occasion. Ten years later, he remembered, Dr. Marion Sims was the orator; speaking before a large audience in the hall of the Historical Society. Dr. Barker said he had been much interested in the admirable address of Dr. Noyes, and particularly in the practical deduction and eloquent plea with which it concluded. Although the Academy was now in a very flourishing condition, he believed that it was still in a process of evolution, and that it had a glorious future before it. Under its auspices he hoped to see at no distant day such facilities offered for scientific investigation as had been referred to in the paper. There was no city in which there was so much individual wealth as in New York, and he had little doubt that enlightened citizens would be found who could be induced to supply the means for the establishment of a great centre of research and teaching.

### Recent Literature.

*A Text-Book of Pharmacology, Therapeutics and Materia Medica.* By T. LAUDER BRUNTON, M.D., D.Sc., F.R.S. Adapted to the United States Pharmacopœia, by Francis H. Williams, M.D., Boston, Mass. Philadelphia: Lea Brothers & Co. 1885.

This work treats of the subject covered by its title in such a novel way in comparison with that in our stereotyped works on therapeutics that it deserves rather more than a passing word of criticism. The keynote of this treatment is struck at the very outset, where Dr. Brunton gives the meaning of pharmacology as "a knowledge of the mode of action of drugs upon the body generally, and upon its various parts;" and again, "Preventive medicine or prophylaxis, is daily becoming more important, and probably before the end of this century, medical men will be employed more to prevent people from becoming ill than to cure them when disease has become fairly established."

First in the order of discussion comes a very scientific epitome of chemical and physical relations of elementary substances, and next the combinations of organic radicals, and in relative order the theory of chemical and physiological reactions, of atomic weight and physiological action, the relations between spectroscopic characters and physiological action, and the relations between isomorphism and physiological action.

The author clearly shows the fallacies by which Blake, Rabuteau, and de Boisbaudran, in the above theories, endeavored to substantiate an explanation of the action of medicines in the living organism; and our author claims that the connection between chemical constitution and physiological action is the most important physiological feature in pharmacology.

Before taking up the consideration of the known action of drugs on animals, Dr. Brunton discusses the circumstances which affect the action of drugs on the living organism, on protoplasm, blood and low organisms, on various organic living tissues, such as muscles, nerves, spinal cord, brain and their appendages, on the circulation, on the digestive system, on tissue change, on excretion, and on the generative system. The discussion of these topics, and of the modes of drug administration form nearly one half of the book, which is worthy of a careful perusal, because undoubtedly a knowledge of these matters forms the only basis of a correct use of drugs either in prevention or cure of diseases. For instance, the *tinnitus aurium* caused by quinine and salicylate salts as well as other medicinal agents can never be fully appreciated unless the function and peculiarities of hearing be properly understood. As our author states: "It is probable that subjective sounds not depending on disturbances of the auditory apparatus, such as sounds of voices, etc., heard in delirium or mania, or as the prodromata of an epileptic fit in certain individuals, or during intoxication by cannabis indica, are due to irritation of these centres." In the discussion of the action of drugs on the digestive system, Dr. Brunton lays great stress on the function of the liver, "the porter to prevent the passage of injurious substances from the intestinal canal into the blood," and speaks of its important function in destroying the poisonous properties of peptones or ptomaines which upon the authority of Seegen are converted by it into sugar and glycogenic substance. He then notices the importance of separating those medicinal substances formerly classed as cholagogues into hepatic stimulants and cholagogues, properly so-called, and a new class of hepatic depressants, "which lessen the quantity of bile secreted by the liver," and among which probably calomel should be ranged. Among hepatic stimulants are classed as the most powerful: dilute nitro-hydrochloric acid, aloes, sodium phosphate, mercuric chloride, sodium salicylate, sodium benzoate, eucynonin, iridin, phytolaccin, podophyllin, sanguinaria, colocynth, and ipecacuanha; as the less powerful: rochelle salts, sodium sulphate, ammonium benzoate, baptisin, hydrastin, juglonein, leptandrin, jalap, rhubarb, and castor bean extract; as cholagogue purgatives: aloes, baptisin, colchicum in large doses, colocynth, jalap, podophyllin, rhubarb, sulphate of potash, sulphate of soda, phosphate of soda, and mercury salts. The green colored stools following the administration of calomel are explained as being due to diminished absorption of bile, which thus passes more rapidly through the intestine and possibly also to its lessened transformation and obstructed decomposition.

Tonics are separated by Dr. Brunton into haematinics or blood tonics, vascular tonics, gastric tonics, intestinal tonics, and nerve tonics. According to our author, alteratives are those remedies which improve the nutrition of the body without exerting any very perceptible action on individual organs. The chief alteratives are arsenic, mercury, iodine, and iodides, cod-

liver oil, sarsaparilla, gold, colchicum, guaiacum, stillingia, sanguinaria, xanthoxylum, and mesereum."

These extracts are sufficient to illustrate the scope of the first half of Dr. Brunton's work, but a more extended examination of his text would give the medical practitioner some most excellent hints for clinical use. The second section treats, in a brief and succinct manner, the subject of general pharmacology. The bias of our author is seen in his expressed hope that the vegetable materia medica will soon be replaced by the use of artificial alkaloids from the use of which, being purer, we may expect "greater constancy of action than we can obtain at present from the natural active principles."

Section III. contains a description and the methods of preparation of the inorganic materia medica, and the last three sections are devoted to the organic materia medica, to the vegetable materia medica, and finally to the animal kingdom. The adaptation of preparations to our United States Pharmacopoeia in these last three sections has been under the charge of Dr. Francis H. Williams. The difficulty of comparing pharmacopoeial products of one nation with that of another makes more evident the necessity of soon adopting an international pharmacopoeia.

It is expressly stated in the United States Pharmacopoeia that, with the special exception of fluid extracts, "all measures of capacity shall be abandoned and quantities shall be expressed in *parts by weights*."

Notwithstanding this rule, which as stated by its committee of revision in the preface to the edition of the United States Pharmacopoeia, published in 1882, (p. xxx), has been carried out except in the special case of fluid extracts, we find it stated in Dr. Brunton's work that dilute sulphuric acid, United States Pharmacopoeia, "is the strong sulphuric acid diluted with sixteen and one-half parts of water by measure; one in ten parts by weight," and the sp. gr. test of 1.067 is omitted. Also, we note in the work before us that acidum sulphurosum, U. S. P. and B. P., is composed of "sulphurous acid gas (SO<sub>2</sub>.61), dissolved in water and constituting 9.2 per cent. of the solution." The United States Pharmacopoeia states that sulphurous acid (acidum sulphurosum), is a liquid composed of about 3.5 per cent. of sulphurous acid gas (SO<sub>2</sub>.61—SO<sub>2</sub>.32) and about 96.5 per cent. of water. This is evidently a noteworthy error, since the dose of the United States preparation would be three times that of the British preparation, or one and a half to three drachms instead of one-half to one drachm.

Again, according to Dr. Brunton's book, dilute hydrochloric acid, U. S. P., contains by measure five and one-half of acid and fourteen of water, or six parts by weight of acid and thirteen of water; again, under the head of dilute nitro-hydrochloric acid, "the proportions in the U. S. P. by measure are nitric three, hydrochloric acid thirteen and one-half, water eighty," in the text of Dr. Brunton's book, whereas the United States Pharmacopoeia states that diluted nitrohydrochloric acid shall be made by weight, four parts of nitric acid, fifteen parts of hydrochloric acid, and seventy-six parts of water. There is not the least shadow of authority for making these dilutions by measure according to the United States Pharmacopoeia, and no well-educated pharmacist in our country should attempt it. The very brief description given in Dr. Brunton's book, on page 435, of the method of preparing fluid extracts of the United States Pharmacopoeia,

hardly expresses the exact statement as given in the official work of the United States. Our fluid extracts are not made like watery extracts, and "instead of evaporating the infusion, (etc.), it is reduced to a small bulk." Our fluid extracts are made by percolation. Sometimes afterwards by evaporation or extension, but the directions are given to exhaust the drug and to make by either of these processes each cubic centimeter of the final product represent one gramme of the crude drug.

It might naturally be expected that a work arranged like the book before us would be difficult to use as an easy manual without a good index. The author has recognized this difficulty, and supplied a very copious general index, an index of diseases and remedies, and an excellent bibliographical index, all of which add much value. These three indices cover over one hundred pages of fine type, and are well arranged for easy reference. There are also nearly two hundred illustrations in the text, which are well executed, and many of them being diagrammatic, make the author's meaning much clearer.

*A Practical Treatise on the Diseases of Children.* By ALFRED VOGEL, M.D., Professor of Clinical Medicine in the University of Dorpat, Russia. Translated and edited by H. RAPHAEL, M.D. Formerly House Surgeon to Bellevue Hospital, Physician to the Eastern Dispensary for the Diseases of Children, Attending Physician Bellevue Hospital Out-patient Department, Diseases of Genito-urinary organs and Syphilis, etc. Third American from the eighth German edition. Revised and enlarged. Illustrated by six lithographic plates. New York: D. Appleton & Co., Nos. 1, 3, and 5 Bond Street. 1885.

The American translator of the eighth German edition of this well-known work presents us with twenty-five more pages of text than existed in the former edition. The book is unusually brought out, both as to type and paper; the plates are of considerable value, and there is much about the work which will be of interest to the general reader.

An excellent article on cerebro-spinal meningitis has been introduced by the American editor. The subjects, however, to which especial attention is directed in the preface are open to a good deal of criticism; thus in the chapter on artificial nutrition, it would seem that the author was scarcely abreast of the times, when he still continues to present as the standard for the analysis of human milk, the results of Vernois and Becquerel, which have for so many years been copied from one book to another and which later investigations have proved to be incorrect to such a degree that they should hardly be placed in the hands of a student without the errors being carefully pointed out. Some valuable information is given regarding tuberculosis in the cow, and the statement made that the milk of tubercular cows is not to any considerable degree a source of infection. The advice regarding the use of condensed milk is very insufficient, and does not embrace such important points as the great reduction of the fat when the milk is diluted, as directed by the author; in fact, the pages devoted to artificial feeding, a subject which should be so thoroughly dealt with in a work of this kind, is deficient in that it does not clearly state the reasons for and against the use of the various foods.

Under the head of difficult dentition, the author still opposes lancing the gums, apparently overlooking the fact that those who lance the gums do not do it so generally as was the custom in former times in every case where there was irritation from the teeth, but that in the especial case where there is local pain, swelling and tension, they lance the mucous membrane of the gum as they would a like condition in other parts of the economy; and that the operation in appropriate cases is often followed by instant relief. This being the experience of many practitioners competent to judge on such a point, it seems hardly wise in an important text-book to so unequivocally condemn the procedure. It is also not the general experience in America, at least, that the cuts from the lancet "heal very badly," or "ulcerate for a long time."

The article on diseases of the nervous system is far from satisfactory, and does not compare well with those on the same subject in the later works on pediatrics published in Germany and England. The author, speaking of the essential paralysis of children, has apparently copied directly from his earlier editions, and has thus been led to overlook the record of autopsies, which now confirm the opinion that the disease is of central spinal origin. Omissions of this kind somewhat shake one's faith in the views expressed on other subjects, and makes one withhold that entire approval which only comes where there is confidence that the latest authentic discoveries have been introduced throughout the whole work.

*Insomnia, and Other Disorders of Sleep.* By HENRY M. LYMAN, A.M., M.D. Chicago: W. T. Keener. 1885. pp. x, 239.

"Tired Nature's sweet repose, balmy sleep."—Young.

The preface commences with the above quotation, and each chapter is headed by a quotation more or less appropriate, one from Goethe, five from Shakespeare, one from Genesis. None of these are very long, and the reader may skip them if so inclined.

The first chapter opens, after the quotation, with a definition. "Natural sleep is that condition of physiological repose in which the molecular movements of the brain are no longer fully and clearly projected upon the field of consciousness." That is, when a man has worked hard, gets tuckered out, lies down to rest, and doesn't know anything, not even his own thoughts, till he wakes up, he has been asleep if he ain't drunk.

The first four chapters are occupied by a very good discussion of the nature and cause of sleep, insomnia, remedies for insomnia, and treatment of insomnia in particular diseases. The chapter on insomnia divides the causes of sleeplessness into two classes: I. those which produce irritation of the peripheral portions of the sensory apparatus; II. morbid states of the central nervous organs. The second class is much the more efficient in giving rise to insomnia, especially the disorders of circulation and nutrition. This part of the subject might have been treated more at length with advantage.

The directions for treating insomnia are judicious, and it is convenient to have the various remedies mentioned together and the value of each discussed. The book will prove handy for reference. Each topic is briefly and concisely considered, some so briefly that

one feels that there is an incompleteness, and wishes the author had said more.

The final chapters on dreams, somnambulism and hypnotism are interesting, many amusing cases are mentioned with more or less fulness; but they are only interesting. No useful conclusions are deduced from the facts. No attempt is made to connect the various phenomena or show their bearings upon other modes of cerebral manifestations.

*Students' Histology. The Essentials of Histology, Descriptive and Practical for the Use of Students.* By E. A. SCHÄFER, F.R.S. 8vo. pp. 245. Philadelphia: Lea Brothers & Co. 1885.

It is a perplexing problem, which, like certain vegetables, sprouts up annually, what text-book of histology shall be recommended to the students, who are just commencing their medical curriculum. In point of number the choice is abundant, but there are very few which one can be even tolerably satisfied with, and none which fully meet the requirements of the case. Professor Schäfer's work is a new attempt to meet the want of a suitable text-book of histology for medical students, and is certainly in many ways an advance upon what we have previously seen in our language. We like especially the combination of directions for making a set of preparations, with a chapter on the tissue concerned, so that the student in following this work learns at once to familiarize himself with the images seen through the microscope, and to associate those images with the general notions which are the really essential ideas for him to acquire and of which the special preparation is only the illustration and the symbol. In fact the union of "practical" and "descriptive" histology is preëminently important and too often neglected. The author's style is excellent, and all his statements are remarkable for their clearness and concision, good qualities which he has already displayed in the ninth edition of Quain's Anatomy. Indeed, the book under review, is essentially a condensation of the histological part of Quain. In both we miss the background of comparative histology and embryology upon which human histology ought to be painted to render it at once vivid and scientific: the want of this is a serious defect.

We can say little in favor of the publishers' part of the work, which has too much stingy cheapness. The illustrations are coarse for the most part, and the author's enemies would not be so unkind as to wish them worse printed. When the cuts, borrowed from Stricker or Ranvier, for instance, are compared with the originals, the degradation they have suffered is pitifully evident.

*Microscopical Methods. Methods of Research in Microscopical Anatomy and Embryology.* By CHARLES OTIS WHITMAN, M.A., Ph.D. 8vo. pp. viii., 255. Boston: S. E. Cassino & Co. 1885.

There has long been an urgent need for a good work on the methods employed in histology and embryology, a need which is now supplied by Dr. Whitman's very admirable manual. It contains a judicious and critical summary of the best which experience and experiment have placed at the service of students and investigators of microscopical anatomy, besides having a special value from including a good deal of valuable matter which has not been previously published and from the skillful collection of methods described incidentally in other publications.

For the working microscopist this book will undoubtedly soon be acknowledged as indispensable. It gives excellent directions for the best methods of preparing the various reagents, and precise rules for the best methods of employing them. It includes also the latest improvements in the methods of cutting, and mounting sections. Hitherto only professional workers have known how great and numerous these improvements have been. In these chapters the author displays much felicitous judgment, so that very little indeed appears in them either in substance or in words which might be omitted. In a second part follows a series of directions for special methods; that is, methods applicable to particular tissues or animals, and these we think will be found extremely useful in practice, for hitherto the vast body of experience accumulated during special investigations has been practically inaccessible. We hope that in future editions the author will greatly expand this portion of his work.

There are some omissions to be regretted, such as the methods of isolating the tubules of kidney, the use of trypsin, methods of micrometry, and some other matters, which have occurred to us, and which we have not found referred to in the book.

The publisher has issued the volume in attractive form, it being well printed on good paper, as indeed a book of such intrinsic value, should be. In conclusion, we give the book, as a whole, unreserved commendation.

*A Treatise on the Science and Practice of Midwifery.* By W. S. PLAYFAIR, M.D., F.R.C.P. Fourth American, from the Fifth English edition, with notes and additions by Robert P. Harris, M.D. Philadelphia: Lea Brothers & Co. 1885.

This standard work is too well and favorably known to require an extended notice of the present edition, which shows but few changes from the edition which preceded it by only a short time. As in previous editions intended for use in this country, the American editor has added materially to the value of the book by his annotations on subjects in which American teaching and practice differ from the British.

Several new methods of performing gastro-hysterotomy devised in Germany are given by the American editor; and the latest statistics in the Cesarean and Porro operations, in the collection of which Dr. Harris has shown such indefatigable industry, are also added. Hicks' method of combined version in the treatment of placenta prævia, as tried in Berlin by Hoffmeier, Behm and Lomer, also receives appropriate notice.

The book will find a welcome place in every obstetric library.

*What to Do in Cases of Poisoning.* By WILLIAM MURRELL, M.D., F.R.C.P. Fourth Edition. London: H. K. Lewis. 1884.

The physician, when called in to a case of poisoning, has presumably but little time in which to consult a book for the purpose of obtaining information which he may reasonably be supposed to carry in his head. This may be said, however, with regard to Dr. Murrell's book; it is very small, and it contains a great deal of useful and accurate information. The work has been carefully revised, and many additions have been made.

# Medical and Surgical Journal.

THURSDAY, DECEMBER 17, 1885.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly, by CUPPLES, UPHAM & CO., Boston. Price, 15 cents a number; \$5.00 a year, including postage, to subscribers in the United States and Canadas. Foreign subscribers are charged the postage in addition.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.*

CUPPLES, UPHAM & COMPANY,

283 WASHINGTON STREET, BOSTON, MASS.

## THIRTEENTH ANNUAL MEETING OF THE AMERICAN PUBLIC HEALTH ASSOCIATION.

THE meeting of the American Public Health Association convened at Washington from the 8th to 12th inst., was one of the largest and most important thus far held. More than thirty States were represented by men engaged in public health work and by private citizens.

The Conference of State Boards of Health was also held at the same time; unusual interest attached to the meeting of the Conference this year, on account of the attempted legislation during the last Congress of the United States.

The bill then presented by the State Boards was based upon the fact that the present National Board of Health has no real support from the various States except such as was naturally given personally to the able and eminent men who composed it. Presidential or political favor might at any time change them, and they did not necessarily represent State or even municipal health organizations. The bill asked for would have given, by proper representatives, some voice to every State in the Union. A short session and opposing interests defeated the measure.

Both the Conference and the Association passed resolutions asking Congress for such legislation as would secure to the whole country some central body with ample power and sufficient money to investigate sources of disease, especially those known to be preventable; to spread abroad through States and municipalities, warnings of disease, and to collect and publish those vital statistics which are absolutely essential to a correct appreciation of the Public Health. While no especial form of bill was presented, it was understood that a representative of the Conference and of the Association, would, at the proper season, appear before the committee of the present Congress and ask for legislation.

It is to be hoped that the existing, but unfortunately, only nominal Board of Health, may be asked to confer with the representatives of these organizations. The American Public Health Association was the parent of the National Board of Health, and has every reason to

be proud of the good work done by the Board in its earlier years. A misfortune, or series of misfortunes, has of late condemned the Board to a useless existence, standing, as it does, in the way of something stronger, and yet unable itself to do the necessary work.

The Conference of State Boards, a new, and in some respects, a more responsible organization than the Public Health Association, as it represents those actually controlling the powers possessed or exercised by the States in public health matters, now joins in the request for legislation to give health questions some proper place among the offices of the general government; and it seems a matter of little consequence whether such a department be called a National Board or a Bureau.

Why is it not possible for the members of the present National Board of Health to join with these important bodies and go before the general government with a strength furnished by union and not likely to be resisted?

President Cleveland though unable to be present, as was expected, at this meeting, wrote a letter expressing his interest in the work of the association, and is known to be well disposed toward public sanitary organizations; in fact there is no real division upon the broad general question of the necessity for some form of national organization; the great, perhaps the only difficulty has been in the rival, often selfish, interests of bureaus already in existence, and of individuals wishing to create new bureaus.

It is therefore, perhaps, as well that these two bodies lately assembled in Washington should not make specific recommendations, but trust to the strength of their statement of the whole question, leaving details to sub-committees presumed to be informed of the wishes of their respective bodies and able to state them.

The election of Dr. H. P. Walcott, although not in the regular order of succession, to the presidency of the Association was an admirable step for its own interests, and a well-deserved tribute to one of our most accomplished sanitarians. Massachusetts having dispensed with his services the rest of the country is eager to avail itself of them.

## ANNUAL REPORT OF THE SURGEON GENERAL OF THE UNITED STATES ARMY.

THE report of this service for the calendar year 1884, is at hand. We are happy to note that for the second consecutive year the number of casualties from actual warfare was zero, the year having been one of peace.

The general health of the army was good; the rate of admission to sick report being decidedly lower than that for the previous year and preceding decade, while the death-rate from all causes shows an equally marked reduction.

Admissions for disease were less frequent, the rate being fully one-fifth lower than for the previous year.

The number of cases treated in hospital during the year was 14,398, or 590.4 per cent. of strength.

The rate of hospital admission compares not unfavorably with that of the United States Navy, which was 888.7 per cent. for the force afloat during the year 1884.

It is of interest to note by way of comparison that the statistical reports of the British Army for troops serving in the United Kingdom from 1870-79 furnish a decennial rate of 809 per cent. and for troops serving at home and abroad 1,025 per cent. of strength admitted to hospital treatment. The German Army for seven years of peace, 1875-81, gives a rate of 315.4 per cent. of strength. The French Army, shows 1872-77, a rate of 310 per cent. treated in *Infirmerie*, and an additional rate of 237 per cent. treated in hospital, and the Belgian Army, 1862-67, gives a rate of 604.4 of strength.

The statistics of the various diseases are given as usual. One item which coincides with the experience of the previous year, but of which no explanation is given, is that cavalry troops, including their recruits, have suffered from enteric fever to a far greater extent than other arms of the service, since they have furnished over seventy-two per cent. of all the cases registered during the year.

All new medical publications are now promptly received by the library, and its use by physicians in all parts of the country is steadily increasing.

Volume VI of the Index-Catalogue, including from "Heastie" to "Insfeldt," forming a volume of 1,051 pages, has, as we have remarked in a previous number of the JOURNAL, been printed, and the edition distributed. The preparation of the manuscript of Volume VII is well advanced, and the first part of it is now going to press.

The manuscript of the third medical volume of the Medical and Surgical History of the War, and the last of the series, is now well advanced toward completion; its earlier chapters are in the hands of the printer. The work will probably be ready for issue during the coming winter.

#### THE MEDICAL EXAMINER SYSTEM IN MASSACHUSETTS.

IN establishing a State Board of Health, sixteen years ago, and in abolishing the old coroner system and replacing it by a system of medical examiners eight and a half years ago, Massachusetts signalized herself as a pioneer in "State medicine." The Board of Health after a remarkably useful and creditable life of ten years fell a prey to politics, from which it has not quite yet been rescued. But in the last ten years many other States have profited by the early example of Massachusetts.

The system of medical examiners has had an existence of eight years and a half, and it too in that time has won for itself such credit that other States have adopted or are preparing to adopt it, encouraged by the satisfaction expressed with it here. Only eighteen

months ago, in commenting upon an act relating to medical examiners, then recently passed in Rhode Island, we "hopefully predicted a continuance of the excellent success which had thus far attended the Massachusetts method of investigating violent deaths."

Under these circumstances we think our readers will be somewhat startled by a paper on this system, recently read before the Boston Society for Medical Improvement, and published in this issue of the JOURNAL, in which the system, as now in operation, is arraigned, and grave charges of incompetency and carelessness are brought against individual members of the body of medical examiners. We hope those who read the paper will not fail to read with equal care the discussion to which it gave rise (p. 585). At the same meeting a committee was appointed to investigate the whole subject as presented and report to the Society. Their report will be awaited with interest, and we prefer to reserve any extended comments on the subject until it shall have been rendered.

Least misconceptions should arise in the meantime, however, we desire to say now that recent inquiries have failed to furnish us with any sufficient reasons for changing the favorable opinion we have always entertained and expressed in regard to the medical examiner law and its operations in the State of Massachusetts. It is not perfect, as few things are, and it would be easy to point out details in which, were the Legislature willing to incur the expense of an ideal medico-legal machinery, its operation could be greatly improved. But we think the contrast presented with the state of things obtaining under the old coroners, the few changes which it has been found necessary to make in the original act, and the character of the men, with very rare exceptions, whose services have been secured to the State at no greater cost than the old methods entailed, stamp the present system as a remarkable success.

During the eight and a half years that the medical examiners have been in existence, an aggregate of ten thousand cases have come under their official consideration—about twelve hundred a year—and we have strong reasons for stating that the number of cases in which carelessness or incompetency can be justly laid at their doors is very small, and the number of cases in which their deficiencies have brought injury to the innocent or caused the escape of the guilty must, in the nature of things, be very much smaller still.

The only particulars in which it has been found necessary to amend the original law are three, namely: the medical examiner cannot draw his fee for an autopsy without the signature of the district attorney; provision has been made for an expert medical witness, if necessary; an inspection and annual tabulation of the examiners' reports are required.

#### A NEW CARDIAC TONIC.

PROFESSOR Germain See has announced to the Academy of Medicine the discovery of a new alkaloid, which, he believes, has a wonderfully tonic and regu-

lating action on the heart; it is derived from a variety of broomtop, the *Spartium Scoparium*, and has been designated *Sparteine*. This alkaloid is in liquid form, is very bitter, is insoluble in water, and has for chemical formula:  $C^{20}H^{28}N^2$ . By reason of its pronounced alkalinity, sparteine forms with acid, salts which are soluble and crystallizable. Only the sulphate has thus far been used in experimentation.

Sparteine was discovered by Stenhouse, in 1850; Miltz experimented with the sulphate in 1863, and Fick ten years later; it was again taken up in 1880 by Raymond and Bochefontaine, and still later, by Laborde, and in 1883, Germain Sée first mentioned it among the cardiac medicaments.

According to the researches of the latter, an aqueous solution of ten centigrams of sparteine increases in a remarkable manner the force of the heart and pulse; its effects are quite as marked as those of digitalis and convallaria, while being much more prompt and more enduring. If the cardiac rhythm is disturbed, it is almost immediately set right by the action of the medicament; no medicine, says Professor Sée, can be compared with sparteine in its power to regulate intermittent or otherwise disorderly pulsation. It also quickens the heart contractions in grave cases of atony with slowing of the cardiac movements; in this respect, sparteine resembles belladonna.

All these phenomena appear at the end of an hour or two, and the effect is kept up for several hours after the suspension of the medicament. During this time, the organic forces are augmented and respiration is improved. Professor Sée's observations concerned six patients, whose pulse was examined by Marey's sphygmograph before, during, and after the administration of the medicament. Of these patients, two were effected with atrophic degeneration of the myocardium, with general debility, permanent oppression, and excessive feebleness of the heart's impulse, and almost imperceptible pulse. Under sparteine, the tracings recovered the normal type, and continued normal for several days.

Another patient with mitral valvular insufficiency and irregularity of the heart and pulse, was similarly benefited. In a fourth case, the rhythm of the heart was still more disturbed by valvular incompetency; the heart's action after exhibition of sparteine, became steadied and strengthened. The fifth case was one of dilatation of the heart, caused by arterial degeneration; there was pronounced arrhythmia, with edema and albuminuria, depression, and slowing of the pulse; "under the influence of sulphate of sparteine, the pulse became regular, the impulse of the heart was augmented, and the movements of that organ accelerated."

The sixth case was one of cardiac asthma, with albuminuria; the pulse was small and irregular; "forty minutes after the ingestion of the remedy, all was changed—the regularity and the force had returned."

Such, according to Professor Sée, are the advantages likely to be derived from sparteine in these grave heart troubles, and this medicine seems indicated when-

ever the myocardium is weakened, whether from fatty degeneration, or valvular insufficiency, with failure of compensation. "When the pulse is irregular, intermittent and arrhythmic, sulphate of sparteine rapidly re-establishes the normal type. When the circulation is slackened, this medicament seems immediately to oppose this functional trouble, while maintaining, or even augmenting the acquired force of the heart muscle."

#### MEDICAL NOTES.

—The story is told in the daily press of Mme. Nétalie, an actress of Paris who has recently died, that in 1836 while playing in pantomime at the Folies Dramatiques she had a cataleptic attack which was mistaken for death and was placed in a coffin. Not till the first tap of the hammer on the lid did she rouse from her trance. Two years later she returned to the stage and acted for thirty years, when she retired upon a pension. The last time she was placed in a coffin the hammer's tap failed to rouse her.

—One of the resignations from the International Congress not previously noted in these columns, is that of Dr. R. Palmer Howard, Dean of the McGill Medical Faculty, who was appointed a vice-president. The *Medical News* remarks "that the Canadian members have been placed in an awkward position in regard to the Congress, being to a certain extent foreigners, and being asked to join the organization merely out of courtesy, they did not feel disposed to join in the family quarrel. They, although altogether disapproving of the ousting of the old Committee, thought it better to do nothing, though most of them, if they were asked to reply to the circular advising them of their reappointment, would decline to have anything to do with the Congress as at present constituted."

—Apropos of the use of cocaine in sea-sickness, recommended by Professor Manassein, a correspondent to the *British Medical Journal*, November 17th, writes, in regard to the case of his son, aged twenty-four, who sailed for Calcutta, and who, on former voyages, had suffered excessively from sea-sickness. "He was given a solution of hydrochlorate of cocaine (1 in 1,000). He started on October 5th, and writing from Port Said, reported as follows: 'Sailing on Monday I was ill on Tuesday night and Wednesday morning, but quite well between the attacks. Once more, when the weather was very rough, and the ship rolling terribly, I felt squeamish, but two teaspoonful of the cocaine put me all right.' He adds: 'I have missed only three regular meals, but had mine at these times on deck. Only one other passenger has suffered less than I have; all the others have been very ill. Other voyages, I have always been the worst on board; and I think the cocaine must have the credit of the improvement.'"

—A Washington correspondent of *Science* says that "the museum of hygiene, in connection with the office of the surgeon-general of the navy, is not so generally

or widely known as is the army medical museum. It has undertaken some investigations, however, which, if brought to a successful issue, will be of great value to the general public, and will not fail to bring it into a deserved prominence. The interest of a naval surgeon in hygienic matters arises primarily, no doubt, out of the fact that he has to do with the health conditions of men necessarily crowded into a small space. Whatever may have been the origin of this hygienic museum, it will be everywhere admitted that much can be accomplished by it if its management be wise and liberal. An important step has been announced by the surgeon-general in the statement that a complete system of iron and lead pipes, with fixtures, is being erected on the outside of the museum building for the purpose of making an exhaustive series of experiments, covering all disputed points in reference to trap siphonage and the utility of the mechanism of water-closets, traps, water basins, baths, sinks, etc. Observing stations have been established at each of the three stories, and the investigation is to include microscopical and chemical tests of the action of sewer air and different waters on pipes and tanks. When completed, the results are to be at the service of the public."

—Something of a controversy has arisen between *Science* and *Nature* regarding the method of admission into the Royal Society, which the former periodical criticized as involving the French system of canvassing the Fellows of the Society, and a competitive examination. These criticisms were based on Professor Chrystal's address to the British Association. *Nature* thus describes the method of election: "The friends of a man, who are already in the society, and who think he is entitled to the coveted distinction, prepare a statement of his services to science, in many cases without consulting him in any way. This paper thus prepared, is sent around to other Fellows of the Society, who are acquainted with the work of the candidate, and who sign it as a testimony that they think he is worthy of election. In this way, when the proper time arrives, some fifty or sixty papers are sent in to the council for their consideration. In the council itself we may assume that the selection of the fifteen is made as carefully as possible, in view not merely of individual claims, but of the due representation of the different branches of science. It is not for us to state the safeguards or mode of procedure adopted, but we think we may say that the slightest action opposed to any member by the candidate himself would be absolutely fatal to his election. Finally, we may say that, years back, when a heavy entrance-fee had to be paid, there were cases in which the question had to be put to one whose friends were anxious to see him elected, whether he would accept election. The small yearly subscription of £3, now the only sum payable, makes even this question unnecessary at the present time. Nearly forty years ago the Royal Society determined to limit the yearly admissions to fifteen; the council has the responsibility of selecting the fifteen who are to be nominated for election, a general meeting of the

Society, reserving to itself the right of confirming or rejecting such nomination, but for thirty years that right has not been exercised."

## BOSTON.

—Dr. D. F. Lincoln was awarded the second prize for the best essay on School Hygiene, as offered by Mr. Henry Lomb, of Rochester. The committee of the American Public Health Association did not award any first prize.

—A school teacher in the suburbs of Boston recently punished a pupil for telling an untruth by putting cayenne pepper on his tongue. In the course of about two weeks he died of diphtheria. The friends of the boy naturally claimed it to be a result of the punishment. An investigation satisfied the school committee that it was nothing but a coincidence, but they wisely passed a vote disapproving of this mode of punishment.

## PHILADELPHIA.

—The new building for the Philadelphia Polyclinic College on Broad street will soon be ready for its occupants. The attendance at the college by the students from all parts of the country has increased beyond the capacity of the present quarters at Thirteenth and Locust streets. The new building will contain more hospital wards and private rooms for pay patients, and the dispensary service will be given more attention. The Journal edited by the faculty will be doubled in size after the first of the year.

### 

## A NEW TEST FOR HUMAN MILK.

DR. HÉLOT (Lyon Medical, October 18th), has discovered a method at once simple and practical to test the quality of woman's milk. While, of course, chemical analyses are reliable, yet they are so long and difficult that M. Tarnier has recommended physicians to accustom themselves to recognizing the richness of milk by the sight. Over this method, that of M. Hélot has the great advantage of precision. It consists of a comparison by means of a dropper of the number of drops in a volume of distilled water at 15°, with that in an equal volume of the milk. Good milk, that which will cause a gain of 25 gm. per day in the weight of the child, gives a proportion of 35 drops to 30 of distilled water. The number of drops may vary, increasing to 36, 37, or 38. The milk is then of superior quality. If, on the contrary, one gets only 33 drops, or less, he should mistrust the milk. The Pravaz' syringe allows of the accurate accomplishment of this examination, it only being necessary to remember the ratio of 5 to 6 between water and good milk.

The test should be applied to each breast in the middle of the nursing.

## THE INTERNATIONAL MEDICAL CONGRESS OF 1887.

A MEETING of members of the medical profession interested in the International Medical Congress in 1887, to which prominent medical men from a number of cities were invited, was held at the Hall of the College of Physicians, Philadelphia, December 1, 1885. Dr. D. Hays Agnew in the chair.

It was stated that official notice had been given of the election, as members of the present Executive Committee of the Congress, of Drs. J. S. Billings and J. M. Brown, of Washington, D. C.; Christopher Johnston, of Baltimore; George J. Englemann, of St. Louis; and J. M. Da Costa and William Pepper, of Philadelphia. These gentlemen are reported to have declined the appointments.

A general and strong expression of opinion was made in support of the American Medical Association and its Code of Medical Ethics, and sincere regret was expressed that hasty action on the part of the Association, and the introduction of false issues, had imperilled the success of the Congress. It was made entirely evident, however, that the acceptances of the above elections would not be regarded as affording any adequate guarantee for the future scientific conduct of the Congress, and consequently would not be followed by any coöperation on the part of the leading members of the profession now unwilling to join in that work. As an evidence of the earnest desire which is felt for the restoration of harmony upon this subject, and for the reorganization of the Congress on a basis which would command general support, and thus insure success, the view was unanimously expressed that if the present Executive Committee should unite with them the original enlarged General Committee, and recommence the organization *de novo*, this course would insure the desired result.

## Correspondence.

### LETTER FROM WASHINGTON.

#### MEETING OF THE AMERICAN PUBLIC HEALTH ASSOCIATION.

WASHINGTON, Dec. 4, 1885.

MR. EDITOR.—The thirteenth yearly meeting of the American Public Health Association will be memorable in the annals of this prosperous and powerful organization. The attendance was large, as it doubtless would have been at any reasonably accessible point, for the members are men who are very much in earnest in their work; but the facts that the place of meeting was the capital of the nation, and its time during the session of Congress, doubtless tended to augment the number present, for Washington is a singularly attractive city, and is especially so when the country's Legislature is assembled.

It was hoped that President Cleveland would honor the Association by his attendance at some session; but his official duties in connection with the convening of Congress were so onerous that he was unable to spare sufficient time. But, in the autograph letter which he sent to the Association, he expressed much disappointment at his inability to be present, and a very hearty and intelligent interest in the subject of public health, especially in the improvement of the hygienic circumstances of the laboring classes.

Through personal sources it was learned that the President's words of regret were not intended to be merely formal, for he really would have liked to show his interest by his personal presence. However, as this could not be, he held a special reception for the Associates, at the White House, on Thursday afternoon, even though it was cabinet-day, and greeted the members with cordial affability. As the Society desires legislation on various matters of importance at this session, this friendliness of the chief magistrate toward the leading sanitary organization in America is a source of much encouragement. President Cleveland was uni-

mously elected an honorary member of the Association—the first and only one it has made.

The awarding of the prizes offered by Mr. Henry Lomb, of Rochester, New York, for four popular essays on specified subjects attracted marked attention. The labor imposed upon the judges of the papers on two of the subjects was very great, there being thirty-six dissertations on healthy homes and food for the working classes, and twenty on the sanitary conditions and necessities of school-houses and school life, some of them very long; but the character of the gentlemen composing the committees is a guarantee of the care and thoroughness which they brought to their task; and, while none but they as yet know the quality of the productions which received their approving votes, it is unlikely that anybody will be dissatisfied with their decision, except the unsuccessful competitors. Only one first prize was awarded, that to Dr. Sternberg, for the essay on disinfection and individual prophylaxis against infectious diseases; the committee on the school-hygiene essay reported that, as none of the papers displayed originality, no first prize on that subject would be given. But it seems probable that Dr. Lincoln would have received a first instead of a second prize, if he had not already written so fully and ably on the subject of school-hygiene that he was obliged to quote largely from his own contributions.

As only \$1,100 of the \$2,800 furnished were distributed by the judges, Mr. Lomb, after deducting the cost of copying the sixty-eight essays with a type-writer, offers the remainder in prizes for 1886, on topics kindred to those of this year. The exact subjects are not yet announced. In addition to this, he proposes four prizes for plans for inexpensive houses, adapted to the needs and purses of working men. Such action on the part of a man whose means are not large is an example of a most generous spirit, and an enlightened desire to benefit the common people, which deserves wide and grateful recognition and frequent imitation. The Association gracefully expresses its appreciation of Mr. Lomb's munificence by making him its first life-member. Cheap and popular editions of the successful essays are to be published and given the widest possible distribution, in order that their teachings may reach the classes for whose benefit they were written.

In the election of its new president, the Association departed from a usage which has obtained for nearly its entire existence. It has been customary to promote the first vice-president to the presidency, and the second vice-president to the first vice-presidency. If this method had been pursued this year, the Hon. Erastus Brooks, a member of the State Board of Health of New York, would have been elevated to the highest office. But there has been growing a recognition of the undesirability of a custom which so limits the opportunities for bestowing the Society's honors upon its prominent members, and this year the thought took a very definite shape. It was seen to be important that the Association should have at its head an accomplished sanitarian, and one whose ability has been amply demonstrated. Such a man is Dr. Walcott, of Cambridge, and the Association takes peculiar satisfaction in the belief that, in selecting him to conduct its affairs for the ensuing year, it not only gives voice to the high esteem in which he is held by all who know him, but puts the stamp of its condemnation upon the detestable methods by which Massachusetts was deprived of his valuable services as a member of its Board of Health. All wish and expect from him a wise and happy administration.

Not only was custom disregarded in the selection of president, but gentlemen entirely new to the vice-presidencies were chosen to these offices; and there is no suspicion that personal antagonism has dictated the overthrow of the former usage.

The Canadian health-boards sent most agreeable representatives, to whom the good will of the American members was shown by the unanimity with which an invitation to hold the next meeting in Toronto was accepted, and by the election of the senior Dr. Covert, president of the Ontario Board of Health, to the first vice-presidency. From present appearances, the Canadian meeting will be

very large, for everybody seems anxious to attend, anticipating that the entertainment will be as handsome as the invitation was cordial.

The papers were for the most part able productions, and will well repay perusal when they appear in the transactions. The most exhaustive were the report on disinfectants, which was presented in pamphlet form, and is to be issued to the profession and general public as a separate treatise; and the report of Dr. Rauch, of Illinois, on maritime quarantine from the St. Lawrence to the Rio Grande. Those which seemed most interesting to the listener were Dr. Lee's debit and credit of the Plymouth epidemic, and Dr. Wight's disinfection of sewers, both admirably written articles. The author of the former traced the celebrated plague of the Pennsylvania town to a case of typhoid fever in Philadelphia, and had ascertained, by exact inquiries in the case of each patient, that, reckoning the actual outlay of money in paying the expenses of sickness and burial, and the loss of productive labor, the entire damage amounted to \$711,000. To balance this stands the State Board of Health of Pennsylvania, which would not now exist but for the demonstration of the necessity for it which the legislature found in the devastation of the Plymouth epidemic. We shall look for very superior results from the Board of the Keystone State, after such a specimen of its work as this paper records.

Dr. Wight detailed with much sprightliness of diction the method which he pursued in the disinfection of the badly-constructed sewers of Detroit, and claimed that an immediate and pronounced diminution of diphtheria and scarlet fever followed as a consequence on two occasions.

The drenchings with strong copperas solutions and fumigations with sulphurous acid are to be repeated periodically, and further reports from the Michigan metropolis will be awaited with great interest.

But even this successful meeting was not without its blemishes. Some men seem to be incapable of learning that a paper an hour and a half long is rather trying to the patience of the most kindly auditors, and others apparently think that they can best please a scientific body by common-places and platitudes which are clothed in turgid phrases, and delivered with violent gesticulations and startling robustness of voice. When will presiding officers come to understand that the twenty-minutes rule is more honored in observance than in the breach? Some of us are radical enough to believe that an absolute enforcement of this rule contributes as much to the comfort of a meeting as any one thing can, and we look to our new president to reform the too common usage in this regard.

At the Conference of State Boards of Health, twenty-six States were represented. Dr. McCormack, of Kentucky, was elected president, and Dr. Conn, of New Hampshire, secretary. No definite decision as to what federal legislation is desirable was arrived at. A committee was appointed to report next year on methods of mutual assistance, and it is expected that most of the Boards will, without a formal agreement, immediately institute a system of inter-state notification of contagious diseases.

The Conference will meet one day before the Public Health Association for 1886, thus gaining the time for the want of which it failed to accomplish much that it could otherwise have done this year.

## REPORTED MORTALITY FOR THE WEEK ENDING DECEMBER 5, 1885.

Deaths reported 1,927: under five years of age 636; principal infectious diseases (small-pox, measles, diphtheria and croup, whooping-cough, erysipelas, and diarrhoeal diseases) 330, consumption 234, lung diseases 223, diphtheria and croup 224, diarrhoeal diseases 41, typhoid fever 40, scarlet fever 35, malarial fever 21, whooping-cough 13, cerebro-spinal meningitis ten, small-pox two, measles two, erysipelas one, puerperal fever one.

From scarlet fever, Brooklyn 14, New York nine, Philadelphia and Providence three each, Boston and Cincinnati two each, Cambridge and Malden one each. From malarial fever, New York eight, Brooklyn seven, New Orleans six. From whooping-cough, New York eight, Brooklyn three, Philadelphia and New Orleans one each. From cerebro-spinal meningitis, New York five, Cincinnati, Worcester, Holyoke, Chelsea and Newburyport one each. From small-pox, New York two. From measles, New York and Boston one each. From erysipelas, Brooklyn one. From puerperal fever, New York one.

In 105 cities and towns of Massachusetts, with a population of 1,244,481 (population of the State 1,941,865), the total death-rate for the week was 14.33 against 18.38 and 14.94 for the previous two weeks.

The meteorological record for week ending December 5th, in

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM DECEMBER 5, 1885, TO DECEMBER 11, 1885.

BIRMINGHAM, H. P., assistant surgeon and first lieutenant. Ordered for duty at Camp Grant, Riverside Park, New York City.

BUSHNELL, GEO. E., assistant surgeon and first lieutenant. Ordered for duty as post surgeon, Fort Preble, Me.

WILSON, WM. J., assistant surgeon and captain. Ordered for duty as post surgeon, Plattsburg Barracks, New York.

APPEL, D. M., assistant surgeon and captain. Ordered for duty at Jackson Barracks, Louisiana. S. O. 256, Department East, December 4, 1885.

EVERIS, EDWARD, assistant surgeon and first lieutenant. Ordered from Department Columbia to Department Arizona. S. O. 279, A. G. O., December 5, 1885.

POLHEMUS, A. S., assistant surgeon and first lieutenant. Relieved from duty at Presidio of San Francisco, Cal., and ordered for duty as post surgeon at Fort Halleck, Nev., relieving Acting Assistant Surgeon Loren N. Clark, United States Army. S. O., 113, Department of California, November 30, 1885.

#### OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING DECEMBER 12, 1885.

LEPPINCOTT, GEORGE C., passed assistant surgeon. Detached from navy yard, Washington, and wait orders.

BRASL, C. W., passed assistant surgeon. Ordered to the United States Revenue Steamship "Dale," as relief of Passed Assistant Surgeon G. P. Lundsen.

LEWIS, C. P., passed assistant surgeon. Ordered to naval hospital, Washington.

LOVING, P. A., passed assistant surgeon. Detached from United States Revenue Steamship "Wabash," and wait orders.

#### SOCIETY NOTICES.

BOSTON SOCIETY FOR THE MEDICAL SCIENCES. A meeting of the Society will be held at the Harvard Medical School, Tuesday, December 22, at 8 P. M. Dr. H. C. Fred will give an account of the methods of work in Koch's laboratory and exhibit

For the week ending November 21st, in the Swiss towns, there were 23 deaths from consumption, lung diseases 18, diphtheria and croup nine, diarrhoeal diseases seven, typhoid fever three, small-pox two, whooping-cough and erysipelas each one.

The death-rates were: at Geneva 12.1; Zurich 13.6; Basle 14.4; Berne 27.3.

In the 28 greater towns of England and Wales, with an estimated population of 8,806,446, for the week ending November 21st. Deaths reported 3,579; infants under one year of age 858; acute diseases of the respiratory organs (London), 454, measles 86, whooping-cough 79, fever 55, scarlet fever 39, diarrhoeal diseases 37, diphtheria 32, small-pox (London, Liverpool and Manchester one each) three.

The death-rates ranged from 11.2 in Bradford to 27.9 in Derby; Birkenhead 18.5; Birmingham 17.2; Brighton 17.3; Hull 13.7; Leeds 21.9; Leicester 19.2; Liverpool 21.5; London 19.9; Manchester 24.7; Nottingham 20.7; Sheffield 18.8; Sunderland 18.7.

In Edinburgh 20.4; Glasgow 26.8; Dublin 30.3.

Boston, was as follows, according to observations furnished by

a series of cultures and microscopic specimens of micro-organisms. The profession are cordially invited to be present.

W. W. GANNETT, Secretary.

## Lecture.

## ON NEW ANALGESIC MEDICAMENTS.

A CLINICAL LECTURE, BY PROFESSOR DEJARDIN BEATMETZ.<sup>1</sup>

My last lecture was devoted to medicaments which produce sleep (hypnotics); to-day I propose to speak about analgesics, that is to say, medicinal substances which antagonize pain. I shall dwell more particularly in this lecture on the new analgesics: aconitia, napelline, gelsemium and gelsemin, piscidia erythrina, and finally on the local anesthetics such as subcutaneous injections of chloroform and pulverizations of chloride of methyl.

The type of analgesic medicaments is morphine, and if opium and its derivatives are considered as hypnotics, it is because they give repose by banishing all painful sensations. I cannot here enter into the subject of subcutaneous injections of morphia, which I have treated at length in my Clinical Therapeutics. What I can assure you, however, is that the older I grow the more chary I become in the use of morphine, for despite the marvelous properties of this alkaloid which is far the most active of analgesics, its dangers and disadvantages are such that I reserve its employment for exceptional cases only.

In fact the superiority of morphine constitutes one of its most serious evils. Let me explain:—Whenever a patient has once made use of morphine, thereafter all other analgesics seem inefficacious and unsatisfactory, and he looks continually to the same medicament for the relief which he has experienced, and when the pain is entirely gone he will have become so accustomed to his morphia that he will with difficulty, if at all, free himself from the habit. This is the history of almost all cases of morphomania; at the beginning it is for a neuralgia, a mild attack, perhaps, for which the patient has recourse to the injections of morphine, and little by little he becomes habituated to the poison, and when he is once a victim to this vice, it will be very difficult to make effectual opposition to it.

Do not, then, resort to these injections except when you have to do with intense pain caused by cancer or in the last periods of pulmonary diseases; here morphine is really advantageous, enabling us to prolong the life of these unhappy beings and make them tolerably comfortable. In all other cases, never allow the patient to make the injections himself, and only resort to them when the pain becomes too severe, and not till after you have employed all the other means in your power.

Aconite, after morphine, is one of the most powerful analgesics, and the subject of aconite and aconitia deserves to arrest your attention for a few moments, illustrating, as it does, how complex is the application of medicinal plants to medicine, and how cautious we should be in deducing positive conclusions from any observed sequences in the therapeutic use of these agents.

For a long time, practitioners in this country made use of preparations from aconite leaves, and the results obtained were very problematical. Oulmont in showing us that the active principles of the plant vary according to its origin and the parts used, made apparent the causes of the seeming inertness of these aconite preparations, for the leaves contain very little of the

active principles, while the roots are largely impregnated with them. Hence it is that in England, where the Pharmacopœia sanctions the usage of the root alone for the official preparations, very energetic results have been obtained from these latter. Duquesnel, in extracting from these aconites a definite crystalline principle, added still more to our knowledge of this plant, and his studies, in connection with Laborde, of aconite and aconitia have been of great value.

There exist two great varieties of aconite, the one growing in Europe, the other in Asia; the French aconites may be subdivided into the *aconitum anthora* and the *aconitum pyrenaicum* with yellow flowers, the *aconitum napellus* and *aconitum napellus neomontanum* with blue flowers; the type of the Asiatic aconites is the *aconitum feror*.

When you analyze these different plants, you find that they contain a crystalline aconitia, an insoluble amorphous aconitia, and another which is soluble, to which Duquesnel has given the name of *napelline*. Moreover, in the Asiatic aconites, there is found another crystalline alkaloid, *pseudo-aconitina*, and an amorphous alkaloid, *amorphous pseudo-aconitina*. Finally, what is still more astonishing, is that according to the origin of the aconites, these alkaloids behave differently with respect to polarized light.

You see before you two solutions of crystallized nitrate of aconitia; the one comes from the *aconitum napellus*, gathered in Dauphiné and deviates the polarized ray to the left by 3°.4; the other is obtained from a plant growing in Switzerland, and is also levogyrous but by 4°.8.

You see how complex is this question of the aconitias, and how different must be the result according to the plant employed. There exist in commerce English and German aconitias, an aconitia of Morson, another of Duquesnel, etc., and all these aconitias have variable therapeutic and physiological action, for the reason that they are derived from plants of different origin. It will then be absolutely necessary, when you wish to prescribe aconite or aconitia to specify the part of the plant and its place of origin, if you write for aconite, and the laboratory where it was extracted, if you order aconitia.

We actually make use almost exclusively of the alcoholic tincture of aconite root, and we add the name of the province, whether of Vosges or Dauphiné. Duquesnel thinks that the tincture is preferable, and he proposes the two following preparations; the tincture of aconite root, and the extract: the latter being much the most active, three to four centigrammes of the extract representing one gramme of the tincture. As for aconitia, it is the crystallized nitrate of aconitia, which you should order, adding the name of Duquesnel, and under the form of granules containing a quarter of a milligramme of the active principle. (In American pharmacy a pill is in use containing 1-200 grain crystallized aconitia).

As for the doses, they are exceedingly variable, and you should always remember that certain persons have a real intolerance of this medicament. I have for my part seen toxic phenomena of great gravity determined by extremely minute doses of crystallized aconitia, scarcely the 1-120 of a grain.

Therefore you will have care that the doses shall be wide apart when you make use of this alkaloid, and order, for instance, a granule of a quarter of a milligramme (1-210 grain) every six hours, giving three-

<sup>1</sup> Delivered in the Hôpital Cochin, and printed from advance sheets.

tions not to exceed four granules in the twenty-four hours. It will even be necessary to stop the medicine when the patient experiences the first toxic symptoms, such as tingling of the tip of the tongue, and that strange sensation of loss of elasticity of the muscular orifices of the mouth, eyes and nose, when it seems to the patient that the skin of the face is shrunken.

If you make use of the tincture or fluid extract of the root, the dangers of poisoning are less, and you can give ten and even twenty drops three, or even four times in the twenty-four hours. The dose of the extract is one-sixth of a grain, which you can repeat once or twice during the day.

Aconite and aconitina have a very limited sphere of action, which as far as pain is concerned, is confined almost exclusively to the trifacial nerve; its action on the other sensory nerves is much less marked.

By the side of this analgesic effect, aconite has a special action on the circulation; it is an anticongestive vascular medicament from which you may obtain good results, especially in the pulmonary congestions accompanied with cough, of which one of the types is influenza. You know that in this affection I have been in the habit of ordering the following mixture:

Into a glass of warm milk put two tablespoonfuls of syrup of tolu, a dessert-spoonful of distilled cherry laurel water, ten drops of tincture of aconite root, and order the whole to be taken in one dose and repeated three times a day.

Aconitina, as I have told you, has a special influence on the trigeminus, abolishing conscious and painful sensibility, and acting also on the unconscious or reflex sensibility; it modifies the blood pressure, diminishing arterial tension, and lowering the temperature. These are especially the physiological effects which are utilized in therapeutics.

Aconitina has besides another effect of which I must remind you, for it has given rise to several mistakes. I refer to its action on the pupil. Administered internally, aconitina dilates the pupil, and this explains why physicians, seeing this mydriasis, have sometimes thought that the apothecary had made a mistake, and instead of granules of aconitina had given granules of atropine; you will not then be led astray if you should see pupillary dilatation follow the use of this alkaloid.

It is in facial neuralgia that aconitina produces its maximum of therapeutic effects, and for my part, I am acquainted with few neuralgias which are not relieved by this means. When the prosopalgia presents itself under intermittent form, you will do well to associate quinine with the aconitina. You can unite in the same capsule five grains of quinine with one two-hundredth of a grain of crystallized aconitina, or having administered a capsule containing the five grains of quinine, you can give one of Duquesnel's granules, and repeat the dose every six hours till the pain has entirely disappeared.

Aconitina is not, as I have told you, the only active principle obtained from aconitum napellus. There are also found two amorphous principles, the one soluble, the other insoluble. It is to the first of these principles that Duquesnel has given the name of *Napelline*. Thanks to its solubility, napelline may be given subcutaneously. Laborde and Daublin have experimented with napelline, and have shown that this alkaloid is much less active than crystallized aconitina, and that, moreover, instead of being purely analgesic, this napelline possesses quite marked hypnotic properties. They

have also employed this alkaloid in subcutaneous injections in the dose of five-sixths of a grain once in the twenty-four hours, and have never seen toxic symptoms follow. Hence they think that napelline, by its less intense toxic action which renders it more manageable, is a medicament which may be employed to advantage in the treatment of neuralgias.

If you wish to repeat these trials, I advise you to adopt the following method: Make subcutaneous injections of a solution of one-sixth of a grain of napelline in a cubic centimeter of water, and repeat these injections three or four times in the twenty-four hours. Grognot, of Milly, has employed napelline in granules of two and a half milligrammes (one twenty-fourth of a grain), and in the dose of three centigrammes (one-half grain), he cured a rebellious facial neuralgia which had resisted the action of crystallized nitrate of aconitina. But I have no more time to spend on aconite and its alkaloids, and pass to the study of gelsemium.

Gelsemium sempervirens, or Virginian jasmine, has been employed largely by the Americans. It is a climbing plant, with yellow flowers, which grows in the moist soil of Virginia and other of the Southern States. The roots and the stem are employed in medicine; of these a tincture is made, which is given in the dose of ten drops every two hours in facial neuralgias, being especially remedial in dental neuralgia. Remarkable results have been claimed, notably in the intermittent forms of neuralgia.

I experimented with gelsemium several years ago (in 1877), and my pupil, Dr. Eymeri, has given in his thesis the results which we obtained.<sup>2</sup> These results were similar to those of previous experimenters who had studied the therapeutic, toxic, and physiological action of this plant. We found that gelsemium is an energetic poison, and that its toxic action is variable, according to the preparations employed, so that one tincture made with the stem may give small or unappreciable effects, while another, made with the root, may have a marked toxic action in the same dose. I have myself seen a patient who experienced severe symptoms of poisoning from thirty drops of the tincture; moreover, quite a number of fatal cases have been recorded from the use of this drug; so that while recognizing the analgesic action of the preparations of gelsemium (inferior though this be to that of aconite and its alkaloids) it has seemed to me to be wisest, owing to the acknowledged uncertainty of the gelsemium preparations, to be very chary in the use of this remedy.

It has been recommended to employ, instead of gelsemium, the alkaloid *gelsemin*, discovered by Fredricke, but we know little respecting the action of this active principle, and we ought to be well established with regard to its physiological and toxic effects before giving it a place in therapeutics. Moreover, gelsemium and its alkaloids produce not only paralysis of sensibility, but also of motility, and, as Rouch has well shown, gelsemium is especially a poison of the motor-nervous system. Moreover, Rouch has also pointed out in his experimental researches, as we have also done in our clinical observations, that the effects vary according to the preparation employed.

*Piscidia erythrina*, or Jamaica Dogwood, is of quite recent introduction into therapeutics. The first experiments made with it, by Ott,<sup>3</sup> of Philadelphia, and

<sup>2</sup> Eymeri, on Gelsemium sempervirens (Thèse de Paris, 1877.)  
<sup>3</sup> Ott, on the Physiological Action of the Active Principle of *Piscidia Erythrina* (Arch. of Med., 1881.)

Nagle, in 1881, show it to be narcotic to animals; it is, however, worthy of note that in 1844, Hamilton, of Plymouth, pointed out the analgesic properties of piscidia, and Ford, in 1880, recommended it in neuralgias. Since the labors of Ott and of Nagle, there have been numerous trials with piscidia, and Firth, James Scott, and MacGrotz, Siefert of Berlin, and Vanlair of Liège, have published observations on the therapeutic effects of this remedy.

It was Landowski, in 1883, who was the first in France to call attention to the narcotic and analgesic properties of piscidia. Huchard has utilized it in combination with viburnum prunifolium, and I have myself made in this hospital, and in my laboratory, a great many therapeutic and experimental researches on this subject in connection with my pupil, Dr. Legoy, of Houilles.<sup>4</sup>

Piscidia erythrina is a shrub or tree of the family Leguminosæ, which grows in South America and the West India Islands. Its name comes from the brilliant color of its red flowers, and the stupefying action of its bark on fishes, an action which is very similar to that of cocculus indicus. In America, this plant is designated under the name of Jamaica Dogwood. It is the bark of the root which is used exclusively, and according to the researches of my pupil Carrette, there are found in this bark the following ingredients: a resin, a terebenthinate substance, starch, a salt of ammonia, and finally an alkaloid which Bruel and Tanret have extracted. But here the same difficulties have been met with as in the case of gelsemium, the alkaloid being found in roots of one source and not in those of another, and the therapeutic results being variable and uncertain in consequence.

Besides this different composition resulting from the different sources of this dogwood bark, there is another fact which obscures its physiological action. I refer to its unlike effects on warm-blooded and on cold-blooded animals. While in the case of the former the physiological action, even in large doses is almost nil, in the second, on the contrary, it is very marked. When piscidia is administered to a frog, there are observed convulsive movements, an exaggeration of the frequency of respiration and of the cardiac pulsations, a tetanoid state, and finally death. Piscidia seems to act almost exclusively on the gray elements of the bulbous and medullary centre; it acts also on the ganglionic nervous system.

It is under the form of the powder, or fluid extract, or tincture, that piscidia is administered; the latter seems to us to be preferable. I would recommend the following formula:

R Fluid Extract Jamaica Dogwood . . . . . 3 ss.  
Syrup Aurantii Corticis . . . . . 3 viii.

M Liq. Take a teaspoonful *pro re nata*.

The tincture may be given in doses of from 40 to 50 drops. Huchard associated piscidia with viburnum in the following manner:

Take of

Alcoholic tincture of Jamaica Dogwood . . . . .  
Tincture (or Fluid Ext.) Viburni Prunifolia adgt L.

M To be taken for one dose *pro re nata*.

Thus far the majority of physicians who have given their attention to piscidia consider it as hypnotic. The therapeutic applications which I have made with this

drug do not permit me to share this view, and I regard piscidia as an analgesic very similar in its action to gelsemium, causing sleep because it relieves pain.

Moreover, the first trials made by Hamilton with piscidia (in 1844) were confirmatory of this view. Hamilton was suffering from an intolerable toothache; he applied to the gums, in the vicinity of the tooth, a pledget of cotton wet in tincture of piscidia; the relief was instant and complete. He then bethought himself to apply the same remedy internally for obstinate pain; a marked anodyne effect was realized, with profound sleep. In several cases of rebellious facial and brachial neuralgia, we have seen the pain disappear as by magic under teaspoonful doses of fluid extract of Jamaica dogwood, but like gelsemium it is an untrustworthy analgesic, and this in consequence of reasons above given. So when you prescribe piscidia, you will do well to specify the Jamaica dogwood, this being the only reliable kind. The dose of the tincture is from 30 drops to a fluid drachm; the American fluid extracts are much in use and are given in the same dose. Syrup is a good vehicle for administration.

I shall finish this lecture by a brief consideration of two local means which have of late been used to assuage pain; I refer to subcutaneous injections of chloroform and to the chloride of methyl spray.

Subcutaneous injections of chloroform were first prescribed by Dr. Roberts Bartholow about ten years ago,<sup>5</sup> but their employment in France is of much more recent date. It was in 1877 that Ernest Besnier made known the good effects which he had derived from these analgesic injections, and the following year one of my pupils, Dr. Fournier, recorded in his thesis the results of the trials which I had made with the same remedy in my service at the hôpital St. Antoine. In these experimental investigations I found that if in man the dose of chloroform injected under the skin be raised to about two and a half drachms, sleep is produced, but without anesthesia.

I have given in elucidation of this fact, an explanation which (Claude Bernard had already invoked in his studies on anesthetics. I have shown that in introducing chloroform under the skin, this medicament, before reaching the cerebro-spinal axis, where it produces its elective action, traverses the lungs, where by reason of its extreme volatility, it escapes with the air of expiration, and that the quantity which remains in the blood is too insignificant to make a very powerful impression on the nervous elements of the cerebro-spinal axis; at each inspiration, however, the patient drawing back a certain quantity of air thus charged with chloroform, obtains in this way sufficient of the anæsthetic to produce sleep and an anodyne action, but not profound insensibility.<sup>6</sup>

Professor Bouchard has repeated these experiments from another point of view which had absolutely escaped me. All the animals, and particularly the hares, under whose skin he injected chloroform, succumbed with albuminuria;<sup>7</sup> the explanation of this fact has not yet been found.

Despite their undoubted analgesic action, hypodermic injections of chloroform have not found favor, and I am inclined to attribute the abandonment of them by the profession to the local inflammatory symptoms

<sup>4</sup> Roberts Bartholow, On the Deep Injections of Chloroform for the Relief of Pain, *Præticone*, July, 1873.

<sup>6</sup> Hamilton, *Pharmacæutical Journal and Transactions*, 1881; Ford, *Therapeutic Gazette*; Legoy, Du Piscidia Erythrina (*Bull. de Ther.*, 1885, t. cviii, p. 72, et *Thèse inaug.*, 1884.)

<sup>7</sup> Bouchard, On Albuminuria determined by Subcutaneous Injection of Chloroform. (*Ann. de Med.*, 1884.)

which result from these injections when carelessly or improperly made. When you desire to make use of these injections of chloroform do not forget that it is important to make them penetrate deeply. I advise you, then, to plunge the needle of your syringe perpendicularly, its whole length, into the fleshy parts and there throw your injection. This, moreover, is the way that we generally make our hypodermic injections at the present day; formerly it was the custom to pinch up a fold of skin and enter the needle obliquely parallel to the fold, and introduce the solution into the cellular tissue; the former method is certainly most rapid and advantageous.

It is well understood that these subcutaneous injections of chloroform ought to be made in *loco dolenti*; for this reason their application is rather limited through fear of eschars and abscesses. Hence it is especially in sciatica and lumbago, or even intercostal neuralgia, in all cases, in short, where the cellular tissue permits the deep introduction of the medicament, that these injections should be practised. The quantity ordinarily injected is one cubic centimetre, or about twenty drops, but you may go even farther, and inject at short intervals as much as two or three fluid drachms.

The application of chloride of methyl is of quite recent date, and it was last year, in 1884, that Débove made known to us the good results which he had obtained from external applications of this chemical to the treatment of neuralgia.

Chloride of methyl, which is also called muriated methyle ether, is, at the normal temperature, a colorless gas, with sweetish odor and taste. It may be liquefied by cold or by pressure; it is under pressure that it is utilized in the cases of which I am about to speak. When liquefied, methyl chloride is a colorless liquid which boils at the temperature of  $23^{\circ}$  C. Hence it is that it evaporates immediately when brought into contact with the air, and that by this molecular change an intense cold is produced, amounting to a fall of  $16^{\circ}$ , or even more.

Formerly these refrigerant properties were only employed (as by Malassez) to freeze histological specimens. This easy transformation into gas of liquefied chloride of methyl, necessitates keeping this liquid in very strong recipients. We thought first of all of using the syphon bottles, so much employed for dispensing soda water, but we had to give them up, on account of the bursting of the bottles under the influence of an elevated temperature. To obviate dangers of this kind, we have had to resort to flask-shaped metallic reservoirs, which are rather complicated and rather costly, and this is, it must be confessed, one of the circumstances militating against the general use of this remedy. Nevertheless, now that you can hire these bottles at a reasonable cost, everybody may now avail himself of the benefits of this treatment, as the most of our instrument makers, and even the pharmacists, have these apparatus to let.

The apparatus which I here show you (see Fig. 1) was made by Galente, and it is one on which you can rely. It consists, as you see, of a metallic bottle, which at its superior extremity has two openings, closed by screw caps. By means of the wrench C you remove the screw cap B, and you replace it by another screw cap E, to which is fixed a metallic tube terminated by a filiform opening, by which the chloride of methyl escapes. Then, still with the same

wrench, you remove the screw cap A, and you place the central part of the wrench upon a metallic nut situated in M and which holds the wrench horizontally;

FIGURE 1.

and it will be sufficient for you to turn a little, by means of this wrench, the screw faucet with which it is connected, to cause the chloride of methyl to escape by the filiform opening which I have pointed out to you. The management of the instrument is then very easy, and all you will have to do will be to pass for a few seconds over the painful points the chloride of methyl spray.

The surface of the skin which is thus touched by the methyl chloride spray becomes congealed, pale and hard, and the patient experiences a sensation of smarting and burning provoked by the intense cold which is produced. If the topical effect is too prolonged, a local mortification ensues, which consists in simple vesication or in veritable eschars. Ordinarily, and when the action of cold has been of short duration, the skin turns red and then it assumes on the following days a brownish tint which it may keep for some time.

Hence I cannot too strongly urge you not to prolong the action of the chloride of methyl, and never to let the spraying exceed four or five seconds on the same part of the skin. For the production of vesication and of eschars adds nothing to the therapeutic effect which one desires to attain. When you wish to apply the spray over hairy regions, you must first shave the skin. The therapeutic action of these pulverizations of methyl chloride is exceedingly interesting, and if we may judge by the facts reported by Débove, and several others of our hospital colleagues, and in particular by Dr. Temeson, brilliant cures in obstinate neuralgias have resulted from this treatment. You may also have seen in our hospital service the great benefits which we are deriving from this method,

and when, in rebellious sciaticas, our vesicatories and punctiform cauterizations fail to relieve, we resort to the methyl chloride spray. If it be a case of real sciatica, the pain generally ceases after one or two applications of chloride of methyl. It is not so when we have to do with sciatic pains resulting from affections of the spinal cord, or compressions of the nerves; here the method generally fails; yet in certain cases of symptomatic neuralgia (determined for instance by cancer of the womb) Desnos has had success.

Clinicians have even gone farther, and have applied the methyl chloride to the relief of the phenomenon pain, from whatever source arising; in this way Tenneson has caused to disappear the pains in the side attending acute or chronic pulmonary affections. I think that this is extending the analgesic action of chloride of methyl farther than we are warranted in doing, and that it will be better to reserve it for very rebellious cases. The therapeutic application, then, of chloride of methyl spray is one of the really useful discoveries of the day, and you will do well always to resort to this treatment (which is in itself not at all dangerous) whenever you have to deal with stubborn neuralgia.

### A CASE OF SO-CALLED UNCONTROLLABLE VOMITING OF PREGNANCY.<sup>1</sup>

BY O. W. DOE, M.D.

Mrs. S., twenty-eight years of age, was confined with her first child, December 3d, 1882. In the early months of pregnancy, she suffered much from nausea and vomiting, but every day she was able to retain some solid food. When about four months and a half advanced, the physician in charge made a vaginal examination, and, by pressing the uterus upwards, as he explained it, her symptoms were immediately and permanently relieved.

Her catamenia last appeared on December 25th, 1884, and she conceived on the 2d or 3d of January. As early as the third week of pregnancy, she began to suffer from nausea, which steadily increased.

Simple remedies were ineffectual, and I was called in on February 22d. She was then able to walk about her room, but complained of incessant nausea, general weakness, and a sense of faintness after exertion. Her pulse and temperature were normal. For a week previous, she had taken little else than orange juice. I advised powders of ingluvin and oxalate of cerium; restricted her diet to equal parts of milk and seltzer water, and Valentine's Beef-juice. I saw her again on the 24th. There had been no relief to the nausea and I advised drop doses of carbonic acid and tincture of zedine, with spearmint water as a vehicle, and ether spray to be frequently applied to the spine and epigastrium. The latter gave momentary relief, but soon lost its effect. On the 26th, I ordered injections of bromide of potash and chloral, and scraped beef by the mouth.

There was no relief to the nausea, and on the following day, she vomited for the first time, though not directly after taking nourishment. Just before my visit on the 27th, in attempting to walk from her sofa across

the room, she fainted. From this date, she was under the constant watchfulness of a nurse, so that she might not unduly exert herself, and enemata were ordered of beef-tea, eggs beaten up in milk, grannum and beef peptonoids, each enema containing two drachms of liquor pancreaticus, and half an ounce of brandy. In addition to the enemata which were given four times a day, small quantities of either clam broth, veal broth, peptonized milk, toast water, barley water, squab broth, oyster broth, coffee, wine soup, milk with either soda or lime water, and champagne, were ordered to be given by the mouth at regular intervals, but nothing was retained.

The following remedial agencies were tried, but unsuccessfully:—subcutaneous injections of morphia; bismuth and hydrocyanic acid, alone and in combination; painting of the cervix daily for a week with Churchill's tincture of iodine; vaginal insertion of glycerin tampons blisters to the epigastrium; ice-bags to the spine; ether spray to the spine and epigastrium; chloroform on flannel over the stomach; general massage, and cracked ice by the mouth.

Vaginal examination at this time showed the cervix quite large and directed backwards into the cavity of the sacrum, firm to the touch, and not unnaturally congested; the external os moderately open, and the body of the uterus decidedly anteverted and resting against the ramus of the pubes; pressure in the hypogastrium could scarcely detect it.

From the 27th of February to the 14th of March, while the various remedies above mentioned were being unsuccessfully tried, there was slow and progressive loss of flesh and very marked loss of strength. She was unable to raise herself in bed, and required constant attention, as the attacks of vomiting and retching would come on so suddenly. Her thirst was excessive, and although cracked ice was given freely, she could get no relief except by large rectal injections of tepid water. The bowels, as a rule, had been moved every morning by a soap injection, before beginning the daily rectal alimentation. Occasionally, they would become a little irritable, but the addition of laudanum to the enemata corrected it. The notes for the day of the 14th were as follows:

2.50 A. M., natural and well-formed defecation; 7 A. M., enema of beef-tea, twelve ounces; 9 A. M., intense nausea, with vomiting and a small defecation caused by the vomiting. Ordered ten minims of wine of ipecac in four ounces of water, and one drachm to be given every ten minutes. The first dose was given at 10 A. M.; 10.45 A. M., defecation; 12 M., enema of grannum; nausea intense; 12.30 P. M., vomited nearly a pint of grass-green fluid having the odor, and the patient also stated, the taste of grannum; nausea unrelieved by the vomiting; 1.30 P. M., vomited freely, ipecac omitted; 2.30 P. M., defecation; 2.40 P. M., vomiting; 5 P. M., injection of beef-tea, chloral, twenty grains, bromide, forty grains, and laudanum, twenty-five drops; 8 P. M., defecation; 10 P. M., enema of grannum and laudanum; 10.30 P. M., vomiting; 11.15 P. M., intense thirst and great restlessness; injection of warm water, with bromide and chloral, after which she slept till 7 A. M., and the following day was spent nearly as the preceding.

The os and cervix were now painted with oleate of cocaine, four per cent. solution, but without any effect. One-third of a grain of morphia was given subcutaneously over the epigastrium at 8 A. M. on the 15th, and repeated at noon. The result was a very

<sup>1</sup> Read before the Obstetrical Society of Boston, October 10, 1885.

wakeful afternoon and night, with only temporary relief to the nausea, and was followed by severe headache and such intense nausea without vomiting, that she begged not to have it repeated. She was now so sensitive to outside impressions, that the closing of a door or the appearance of any one unexpectedly before her, would excite vomiting. Emaciation was now very marked about the chest, abdomen, and limbs. She experienced but little desire to change her position in bed or to take notice of surrounding objects, lying usually on her back or right side. Her countenance seemed unnaturally flushed, pulse 98, temperature 97.5°. Dr. Baker saw her at 10 A. M. on the 16th in consultation, and agreed with me as to the nature of the displacement. The vagina was packed, so as to raise as much as possible the uterus up out of the pelvis and away from the pubes. For five hours, she had no vomiting, and said the nausea was less than at any time during the preceding four weeks. At 3.30 P. M., she vomited and displaced, and expelled a portion of the packing. The vomiting after this recurred frequently during the night. The next day, Dr. Baker again saw her at 1.30 P. M., and inserted an anteversion pessary, the impinging parts of which were protected by cotton dressings. At 2.40 P. M., vomited half a pint, again vomited at 4.50 P. M. and at 6 P. M., but very easily and without any straining. At 9 P. M., was suddenly startled, and vomited as a result. At 9.30 P. M., says she has no nausea now for the first time for six weeks. Thirst continues intense and is associated with marked pyralism; complains of a "raw" sensation the whole length of the oesophagus; the tongue is very red and inclined to dryness. After the insertion of the pessary, the uterus could be felt for two inches above the pubes. She passed a very comfortable night until 2 A. M., when she vomited, again at 2.30, 2.15, 6.30, and 7.35 A. M. Nausea was constant after 2 A. M., and attributed by the patient to repeated laudanum injections, which were omitted. During the subsequent day, she vomited only four times and the nausea was very much less. On the 19th, all her distressing symptoms returned in full force, attended by very great prostration. At 2 P. M., salivation became profuse and she thoroughly soaked twelve handkerchiefs and two large towels between that time and midnight. A vaginal examination showed the uterus to be again anteverted, pressing down into the pelvis and pushing the pessary before it.

Glycerin tampons were inserted with the view of raising up both the pessary and the fundus, but the vomiting was attended by so much straining that they were expelled. Dry packing was substituted with decided benefit; the vomiting, though frequent, being unattended with retching, and the nausea very much less. The fluid now vomited was of a light yellowish color, without odor.

Pyralism continues, but less profuse; the irritation of the throat is somewhat relieved by hot poultices, but not sufficiently so as to allow any uninterrupted sleep. During the three following days, she vomited about once in two hours, sometimes half a pint of straw-colored fluid. The only improvement noticeable was the diminished nausea, pulse 110. The uterus could be felt above the pubes, but the pressure of the pessary caused so much irritation that it was removed and a large glycerin tampon substituted.

This was pushed up between the pubes and the body, and followed by a dry tampon. After its

insertion, the uterus could be easily felt for two inches above the pubes. The first tampon was inserted at 9.30 A. M., on the 23d. At 1.15 P. M., there was slight vomiting, also at 3.40; in the interval only very little nausea. At 5 P. M., straining, but no vomiting. During the night, she vomited only twice and drank more water than at any time previous, and had longer interval of sleep. Salivation had nearly subsided, leaving intense dryness of fauces and throat, only relieved by frequent inhalations of chlorate of potash.

Fresh vaginal tampons were inserted morning and night. The attacks of vomiting were now less frequent, the nausea much diminished, but general prostration was so marked as to give rise to the greatest anxiety. Carbonate of ammonium, and five grain doses of quinine were added to the stimulating enemata. On the morning of the 25th, directly after removing the tampons and pressing the body of the uterus upwards and backwards as far as possible, she felt the nausea instantly and completely to leave her. As the uterus seemed to retain its position, I omitted, experimentally, inserting a fresh tampon. There was no return after this time of the nausea, but the abundant secretions in the throat excited vomitings of mucous only. At night, she would awake from the collection of mucous, vomit, and immediately drop off to sleep again. On the evening of the 26th, she took a wine-glass of toast water and retained it. There was no vomiting until 3.05 A. M. On the 27th, took one-half ounce of clam broth at 10.30 A. M.; at 11 A. M., a small piece of toast soaked in water, slept until 11.45, and then took an ounce of rice water. 12.15 P. M., wine-glass of clam broth; 12.45 P. M., a wine-glass of rice-water; 1.40, half ounce of clam broth; 2.40, half ounce of rice water; 3.40, the same.

From this time on, there was no return of nausea or vomiting. Milk and seltzer water were freely taken. The nourishing enemata were continued two weeks longer, though reduced to three, two, and finally, one daily. The patient was able to sit up in three weeks, and drove out two weeks later. Her appetite was remarkably good, and there was no distress after eating. The simple reporting of this case can give no definite idea of the alarming condition this patient was in. Only those who have had similar cases can realize the severity of this affection, and also the relief experienced by the physician in attendance when the crisis is passed.

From the 27th of February to April 4th, three or four enemata were given daily, and for four weeks, nothing was taken by the mouth but cracked ice and ice water. The emaciation was so great that it seemed as if the spinous processes of the ilia would necessarily protrude through the skin. The only alleviation for the nausea and vomiting was obtained by changing the position of the uterus and keeping it from pressing against the pubes.

Dr. Graily Hewitt has recently read before the Obstetrical Society of London, an exhaustive paper on this subject, a résumé of which may be found in the August number of the *American Journal of Obstetrics*.

He has collected thirty-two cases, eight of them being in his own practice, in which the condition of the body of the uterus was carefully noted in the first half of pregnancy. In twenty-three of them there was found to be decided anteversion or ante-flexion; in four, the uterus was retroverted. He attributes the cause of the sickness to the compression of the

nerves in the tissues which are exposed to compression by the displacement. When the sickness continues longer than the first half of pregnancy, he thinks it may be due to hardening of the tissues surrounding the internal os, this condition having been found especially marked in four cases, out of a series of thirteen, in which the condition of the os and cervix was particularly noted.

The treatment advised by him is rest in the supine position, on the back, in those cases where anteversion or ante flexion may be present, and replacement by pessary or any other means that may secure a normal upward movement of the fundus uteri.

Vomiting in these cases usually begins very early; in twenty-four cases out of forty-three reported by Mons. Guéniot, of Paris, it occurred, as in my case, before the end of the first month.

The prognosis in this affection may be stated as decidedly unfavorable. In the thirty-two cases collected by Hewitt, there were eleven deaths and twenty recoveries; the result in one case was not known; seven of these recoveries followed manipulative treatment and replacement of the uterus.

In one hundred and eighteen cases collected by Guéniot, there were forty-six deaths; without abortion, twenty-eight; after abortion or spontaneous premature labor, seven; after induced abortion, eleven. The treatment seems to me should be directed essentially to changing the position of the body of the uterus relative to the cervix. The vomiting begins so early that it does not seem probable that the pressure of the surrounding soft parts, in the first weeks of pregnancy, can act as the exciting cause of so great reflex disturbance.

The treatment by Copeman's method was not tried in the case I have reported, on account of objection offered to it by the family, and a fear on my part of exciting abortion, as I felt that in her prostrated condition, a fatal result would thereby probably follow.

### A CASE IN DOUBT.

BY WALTER M. WRIGHT, M.D., OF ORANGE, MASS., MEDICAL EXAMINER.

ONE morning in 188—, the selectmen of the town of —, directed me to assume charge of the body of one Matilda Ferguson, who had died the preceding day, and make due investigation as to the cause of her death. Such of the personal history and past physical condition of the said Matilda as concerns us at this stage of our paper may be told in a few words. She was a maiden lady of somewhat eccentric life and habits, who had lived the major portion of her seventy-three years in the quiet and seclusion of her own cottage, fully up to the high standard of virtue which Socrates so much desired of his wife. Physically she was thin, bony and angular, and although for the last score of years she had suffered from a cough which gave her the reputation of being marked for a victim of *phthisis pulmonalis*, yet she rarely found it necessary to patronize a physician, and passed for one of those tough, wiry, wearied, chronic kind, which we so frequently see live far beyond our most sanguine expectations, and oftentimes finally die of some acute disease.

During the two or three weeks immediately preced-

<sup>1</sup> Read before the Massachusetts Medical Legal Society, October 7, 1885.

ing her death, Matilda had been much of the time confined to her house and yard; yet had two or three times walked the distance of a mile to call on a sick neighbor, and had on as many occasions, owing to attacks of gastralgia and irritative diarrhoea, accompanied once or twice with thirst and bloody stools, seen fit to call in a physician whose medicine gave early relief, which usually caused a countermanding of the request to "call again to-morrow." Three or four days previous to her death, during the vacation of her old physician, she was seized with a similar but more severe attack, another doctor was called, she rapidly grew worse, sank in a collapse and soon died.

On proceeding to the discharge of my official duties, an external examination of the body made twenty-six hours after death, showed in every respect a remarkably natural appearance, save over the abdomen, which was purple and much discolored on its entire surface; rigor mortis was entirely absent, except in the fingers and toes, and the skin was absolutely devoid the characteristic look and feel of death.

The application of the knife drew venous blood in a somewhat darkened but, at the same time, in a decidedly fluid state, and in no part of the system were any actual clots found.

The opening of the several cavities of the body gave escape to absolutely no odor, in so much that a young lady, present for the first time at such an examination, (which in this case was made in a small, close room), professed that she was able to detect no smell whatever.

The autopsy showed: *First*, a brain whose dura mater was intensely injected and irritated, especially in the region of the vertex, whose superficial vessels were more than usually congested and in whose convolutions, fissures and ventricles nearly six drams of watery serum were found.

*Second*. A right lung whose lower two-thirds were bound by old pleuritic adhesions; a left lung free from adhesions but covered on its anterior surface, particularly of the lower lobe, with a thick gelatinous-plastic exudation, and in whose hemi-thorax there were four ounces of serous fluid. Both lungs were intensely congested and would not collapse on the application of moderate pressure.

*Third*. A heart healthy in every respect, containing a small amount of blood which showed little tendency to form clots.

*Fourth*. A liver, particularly healthy in every part save the extremity of the left lobe, which was slightly hardened.

*Fifth*. A stomach highly irritated at and about both orifices.

*Sixth*. Bowels thoroughly congested throughout, and showing the appearances of severe irritation over a large extent of surface.

*Seventh*. A pair of kidneys and a bladder in which no abnormal appearances could be detected.

*Eighth*. A uterus and vagina whose mucous lining was highly inflamed.

Decoding the results of this examination such as to warrant grave suspicions of the presence of an irritant poison, large sections of the brain, lungs, and liver, and the other organs named entire were separately sealed and submitted to the examination of an expert chemist, Dr. Charles Harrington, of Boston.

While awaiting the result of his investigations, it may not be improper or uninteresting briefly to com-

sider a chapter or two in Matilda's private and domestic life. I have intimated that her life was a lonely and secluded one. Such had been the status until about nine or ten months previous to her demise, when a stranger, a roving adventurer, a Spanish creole, (named Thomas Collins) aged about forty, in appearance and respectability but little above the average specimen of the genus tramp, having by some means obtained a knowledge of Matilda's habits of life and pecuniary condition, by arts and wiles, best known to himself, introduced himself to her notice and good graces, installed himself a member and guardian of her household and to all outward appearances became a most devoted attendant and admirer. During her illness, until very near her end, he alone cared for her and prepared her nourishment. After her death he immediately produced a will properly drawn, signed and witnessed, by which her snug little property, acquired by three score years and ten of the strictest parsimony and frugality, was to pass without reserve into his possession. He made no claim of a marriage but said it had been mutually agreed by them that the survivor should inherit the all of the other, which in Mr. Collins' case might be algebraically expressed by a minus more closely than by a zero. That the peculiar and uncertain ways of the law might by no possible means deprive him of his rights (?) he himself had written the will and the childlike old lady had executed it.

A neighbor, who called once or twice during Matilda's sickness, stated that gruel prepared and administered by the said Collins' hand caused nausea and gastralgia, and that some taken from him two days preceding death produced a marked change in her condition, from the prostration of which she never rallied.

The chemist's report was received three weeks later and from it I quote these words: "The examination has yielded entirely negative results, no poison either organic or inorganic being detected." In a subsequent letter relative to the cause of death, the same gentleman says: "I can only say that it is one of those cases where it is very difficult to form an opinion."

It may not be uninteresting, though perhaps immaterial, to add by way of a codicil that Mr. Collins in a few weeks so far recovered from his grief at the loss of his adopted companion, under the soothing action of the balm of the affections of an ancient widow, possessed of a cash capital of about \$3,000, as to engage himself in marriage to the "blooming old gal" of some sixty-five springs; but having got the above-named collateral well into his own hands, he neglected to present himself before the parson but suddenly departed to other fields and widows fair. A strong arm and officer of the law, reached him in a neighboring State, and when the warm and forgiving-hearted widow gave him the alternative to marry or to suffer, he evidently saw wisdom in the oft-quoted scripture, for he quickly chose the former with all its dread liabilities of the latter.

Now, gentlemen, in this rambling and semi-careless way, I have endeavored to give you the most material points in, and the main outlines of, circumstances bordering on a case which to me was, and still is, puzzling, perplexing and unsatisfactory; and since nothing in the future seems likely to throw any additional light thereon (unless possibly there may be a mysterious

death and consequent autopsy of the present Mrs. Collins) you may very readily understand why I saw fit to label this paper "A Case in Doubt."

### HYDATIDIFORM MOLE OF THE UTERUS.<sup>1</sup>

BY W. A. DUNN, M.D., BOSTON.

On the morning of July 30th, I was called to attend Mrs. M., who was said to be flowing very badly. She was supposed to have been five or six months advanced in pregnancy. When I arrived I found the patient very much exhausted, surrounded by a panic-stricken family, and there was all the evidence of an unusually severe hemorrhage on the clothing and the carpet. Her pulse was very rapid, her breathing accelerated, and her blanched appearance and cold, clammy skin were emphatic evidence of her extreme danger.

On examination I found the vagina filled with clots, which, when removed, were followed by copiously flowing blood. The os was soft, and was of the size of a silver half-dollar. I found the uterus and abdomen much larger than the history of the duration of the case would warrant, and combining the size of the uterus with the hemorrhage I feared the existence of a placenta previa. The extreme conditions of the case demanded that the os uteri should at once be dilated, and the uterus emptied.

These indications and the success of my efforts to follow them I found to be almost in an inverse ratio. However, after long-continued efforts I was able to enlarge the os sufficiently to confirm my diagnosis of placenta previa, and to pass two fingers around it with the hope of touching the fetus. While doing so, the placenta became detached, and I at once removed what I supposed was a portion of the placenta, but what afterwards proved to be all that remained of the placenta. The mass removed was two and one-half inches long and two inches wide. While I was examining it all hemorrhage ceased.

All efforts to find any other portion of the placenta failed, and with the light thrown on the case at this stage I was at a loss to explain the absence of more placental tissue.

As the hemorrhage had ceased, I administered several subcutaneous injections of brandy to stimulate the heart, and prepared the patient for the complete dilatation of the os, which was imperative. During the process of dilatation the patient's agony was so extreme and her resistance was so obstinate that I determined to administer ether, although I did so with considerable trepidation when I considered her exhaustion and the conditions of the case. There was no time to delay, the uterus must be emptied, but the patient declared that she would rather die than submit to the introduction of the hand into the uterus again. To my intense satisfaction the ether proved a potent stimulant to the heart, and soon the radial pulse was beating regularly, and with renewing strength.

The os was soon dilated, and, after a short interval, I was able to insert my hand into the cavity of the uterus, and attempt to reach a foot and turn. To my great astonishment, after groping around on all sides, I was unable to find any evidence of a fetus. On the contrary, I could easily detect the existence of a mass of soft, round cysts which readily came away with my

<sup>1</sup> Read before the Section of Obstetrics and Gynecology of the Suffolk District Medical Society, November 18, 1885.

hand. As I had determined not to remove my hand until I had emptied the uterus, I proceeded to remove as much as possible of the body, which I now supposed was a mole, and which examination verified. It was necessary to insert the hand several times to remove the entire growth, which filled a large basin.

In the meantime the patient's general condition had made a very decided improvement. Her breathing was regular and full, her pulse was regular, easy, and stronger, and her extremities had lost their coldness. Firm pressure was applied to the uterus, which contracted very satisfactorily, and remained contracted after a subcutaneous injection of ergot was twice given. In the meantime several injections of brandy had been administered, and the scene was changed from intense gloom to very great relief on the part of the medical attendant, and rejoicing on the part of the family. When the patient had recovered from the effects of the ether, she expressed herself as feeling comfortable, and showed very few indications of the ordeal through which she had passed.

On questioning the patient and the family I failed to discover any symptoms which might have led to the supposition of the abnormality. It was true the abdomen was larger than what would be expected in a pregnancy of six months, but the enlargement was not especially pronounced. There was no discharge from the vagina of any fluid resembling currant juice, which often exists in cases like the one under consideration. In fact, the condition of the patient was not sufficiently unlike that of other pregnant women to attract attention.

I am indebted to Dr. Charles Schram, my assistant, and also Dr. Dorecy, the family physician, who was unable to respond to the call until late in the progress of the case. The patient continued under his charge through convalescence, which proceeded without a drawback. The ordinary post-parturient treatment was followed. There were no antiseptic injections given, nor was it considered necessary to apply styptic solutions to the uterine cavity at any stage in the case.

**Pathology.** The villi of the chorion sometimes become distended by fluid which collects within them, causing them to swell and assume the form of rounded vesicles comparable to gooseberries or grapes. On account of this analogy they were, for a long time, supposed to be true hydatids. Volpeau was the first to discover that the hydatiform mole has its origin in the villi of the chorion, and the microscopic examinations of Professor Robin exhibited still more closely the true nature of the disease by showing that the envelopes of the hydatiform vesicles have all the anatomical characteristics of the walls of the villi of the chorion.

It is now regarded as certain that the disease known as hydatiform mole is nothing but a dropsical condition of the villi of the chorion. Cazeaux describes the affection as rare. If an ovum presenting the alteration in question be examined, the villi are seen as usual, detached from the surface of the chorion. In some cases the pedicles will have undergone no change in size, while in others they will be slightly dilated. The dilatations, or vesicles, begin to appear where the ramifications commence, the branches of the villi being swollen at intervals. The dilatations vary in size from that of a walnut to that of a filbert, and so down until they become almost invisible to the naked eye. A whole villus is often almost completely metamor-

phosed into a bunch of vesicles almost as large as gooseberries. Upon the larger of these smaller ones are often inserted, and generally by a fine pedicle, a portion of the undilated branch of the chorion.

All the vesicles of the same group are, therefore, connected by pedicles forming groups of the strangest appearance, but, nevertheless, recalling that of the villi in the normal condition. The fluid contained in the vesicles is unusually colorless, transparent as water, and containing albumen in solution. Occasionally the contents are of a reddish color. This dropsical affection may effect either the villi of the chorion, properly so called, or those of the placenta, and in both cases the life of the fetus is nearly always compromised. The dominant fact in the affection is, after all, the arrangement of the umbilical vessels. Should all the villi become dropsical, the death of the fetus would necessarily ensue, and, occurring at a period very near that of conception, it might undergo solution in the amniotic fluid, and thus disappear. The discovery of cysts in the watery, bloody discharge is the only diagnostic sign which will enable us to pronounce with certainty as to the nature of the disease.

**Etiology.** Primiparae are less frequently affected by the hydatiform mole than multiparae, although the actual number of pregnancies seem to exert a less marked predisposing influence than advancing age. The cystic degeneration usually occurs during the first month of utero-gestation. According to Underhill, the latter part of the third month is the limit within which the disease can originate.

There has been considerable discussion as to the etiology of the disease. By some it is supposed always to follow death of the fetus, and the whole developmental energy being expended on the chorion, which retains its attachment to the decidua, the result is its abnormal growth and cystic degeneration.

This view Playfair says is maintained by Gierse and Graily Hewitt, and it is favored by the undoubted fact that in most all cases the fetus has almost entirely disappeared, and by the occasional occurrence of twin conceptions in which one chorion has degenerated, the other remaining healthy until term. Virchow thinks it originates in the decidua, while others have attributed it to some blood dyscrasia on the part of the mother, such as syphilis. It is known to have occurred more than once in the same person. It is known that the disease sometimes follows the death of the embryo, and sometimes it is the result of obscure maternal causes. The establishment of the true pathological relations of the hydatiform mole have led to the abandonment of the once prevalent opinion that the neoplasm might be developed independent of conception.

#### EVERY-DAY CASES OF LABOR, PREPARED WITH SOME REFERENCE TO THE ETHER QUESTION.

BY J. P. BRANFORD, M.D.,

Professor of Obstetrics at the Harvard Medical School.

**CASE I.** A. B., aged thirty; tertipara. In first labor, ether; forceps; post-partum hemorrhage; male child; living. In second labor, no ether; physician left patient promptly. The friends and nurse report repeated fainting, but no very great interference was needed.

Read before the Section of Obstetrics and Gynaecology of Suffolk District Medical Society, November 1, 1885.

She was watched during the pregnancy with unusual care. She is excessively slight, short, thin, and poorly developed.

At 5.30 A.M., as at quarter-dollar piece; head high; membranes unbroken; ether at 8 A.M. At 8.15 I ruptured the membranes; bag already large; dilatation completed; head rather high O.L.P.; flexion rather too great; pains which had never been good, fading out. At 10.30 A.M., suspended ether during six pains, without gain. She complained of being "so faint." At 10.50 A.M. I gave 37 minims of *landanum*; at 11.30 A.M. 16 minims more, adding a little ether to help sleep. Delightful snoring; great feeling of refreshment and strength. At 2 P.M. no progress, no change; general condition excellent; child's heart clear and distinct on left side; head never fairly came down; descent not half-way accomplished. I sent for assistance, and after the arrival of Dr. Kingman, I delivered by version at 3.45 a male, living and well. High and troublesome arrest of the head, necessitating forceps; perineum torn as far as sphincter; placenta safely delivered; no hemorrhage; good contraction wound; perineum stitched. Fluid extract of ergot  $\frac{1}{2}$ .

This patient had formerly used ether for relief in asthmatic attacks. She demanded its employment in addition to other remedies on various occasions during the first four days of her lying-in. I assented with great apprehension. There was no hemorrhage; the ether only did good, and it was of great service in allaying restlessness, ensuring sleep at night and in controlling after-pain. This was my first use of the remedy during lying-in.

CASE II. C. D., aged twenty-seven; secundipara. (Anencephalous fetus nineteen months ago, seven months advanced. In father's family proclivity to mental disease.) This patient whose health has been watched judiciously and most assiduously for a year by her family and by herself, has for four days taken daily, by my direction, one fluid drachm of chlorate of potass, as in the case of the patient just mentioned. I encouraged the employment of chloral and br. sodium gr. x to gr. xxx, whenever this was needed to procure sleep at night.

Three weeks before labor I was called. Condition bad; nausea; frontal headache; pain between shoulders; sp. gr. of urine 1.015; quantity sufficient; much albumen; many epithelial casts. From that date absolute milk diet. After eleven days symptoms entirely relieved; urine wholly normal.

On the day of her confinement, after an excellent night, slight pains set in at dawn. For some days head had been low in pelvis; O.R.A.; xv gr. of chloral with xv gr. of br. sodium at 8.30 A.M.; again at 11 A.M.; at 1.25 P.M. ether; pains then increasing I allowed bag to bulge outside vulva; it burst after the expulsion of head; the shoulders quickly followed, so rapidly that I could not protect perineum from being torn up to sphincter, though it had escaped injury from the head; two stitches. At 2.15 P.M. birth of large, well girl; placenta soon; no hemorrhage. FL extract of ergot  $\frac{1}{2}$ .

CASE III. E. F., aged twenty-nine; secundipara. Slight pains at 1 P.M.; at 3.30 os half dilated; membranes intact; head high; unable to make out position, though I could feel a suture; chloral gr. xv at 3.50 P.M.; again at 1.20; at 5.30 P.M. membranes still entire; could feel a suture in first oblique diameter,

but no fontanelle; head a little lower. Between 5.12 P.M. and 5.45 P.M. patient worried me by yawning constantly. Her pulse and her color, however, remained good. I began to use ether at 5.45, giving it moderately; a large bag of waters formed; it was my design to avoid rupturing the membranes, but the head refused to descend; I could not be sure with what I was dealing. At 9 P.M. I ruptured membranes; head began to rotate, but in spite of improving pains the part of the cranium toward mother's sacrum remained high up. I gave ether freely. At last, at 10.30, I easily delivered with forceps a well girl. I then discovered a second child, the cranium presenting; the bag of membranes very large; the head did not descend. With much difficulty I ruptured membranes high up; the head descended somewhat; I applied first a pair of Braun's forceps, afterward a long pair of Dubois, but I could effect nothing; neither instrument would lock safely. At 11.30 P.M., I turned and delivered the second child, a well girl. The cords were unusually thick with battledore insertion; the placenta were fused, and there was an appendix, almost a third placenta. Manual extraction was necessary. There was no nick in perineum; no hemorrhage; pulse was good and quiet; I gave much ether, even continuing it post-partum, to aid me with the placenta.

This patient convalesced well, though slowly. For two or three days she required the catheter. Moderate cystitis much relieved by washing out with carbolic acid, one per cent.

CASE IV. G. H., secundipara; aged thirty-three. At 3.30 A.M., presenting part beyond reach; membranes entire; pressing moderately; pains increasing at 7 A.M.; during an hour chloral gr. xv. was three times given; some naps. At 8 A.M. os dilated size dollar piece or larger; presentation cranial, thought to be R.A.; membranes entire. At 9 A.M. some escape of liquor amnii; probably high up, as bag hung out from vulva, containing water; birth of well girl, under ether at 10.30 A.M.; placenta rather slowly; perineum perfect.

CASE V. I. J., aged thirty; primipara. This patient long under careful observation; before she reached seven months she was made to keep the bed wholly, and she maintained this posture for many weeks, getting from it the greatest improvement and comfort. The recumbent posture became necessary, because the most moderate exercise, as for instance, walking a few rods on the sidewalk provoked threatening abdominal pains. The patient's mother, four times pregnant, was delivered on each occasion at seven months. An aunt was twice confined at that period. Patient (her brother and sister are all very small people) at eight months. I measured the pelvis; all the external measurements were very good; the resistance of the perineum and the narrowness and rigidity of the vagina made accurate measurement of the conjugate impossible without anaesthesia; I could not conveniently etherize her; approximate results indicated a conjugate of about four inches, and with this, aided by the satisfactory external configuration, I decided to rest content. At 10.30 P.M., slight occasional pains; membranes broken; slight pains from time to time had for seventeen days given threatening of labor but no presentation could be reached; S.L.P. coming round slowly, but well; easy birth of living girl, seven pounds, at 9 A.M. No arrest of head; perineum

sound; placenta soon; from midnight on I gave much ether. Fl. extract of ergot  $\mathfrak{z}\text{i}$ .

CASE VI. K. L., aged twenty-one; primipara. Some tendency to mental and cerebral disease in patient's family; several brothers and sisters died early. Midway in pregnancy patient had long-continued and very distressing eczema of hands and feet. For four and a half months she took  $\mathfrak{z}\text{i}$  of chlorate of potass daily, with very marked improvement in general health; sleep was long secured by the frequent use of chloral and br. of soda gr. v.-gr. xx.

At 6 A.M. os size half-dollar piece; membranes unbroken; head high. At varying periods I gave fifteen grains of chloral; ether was administered from 11 A.M.; progress was excellent till the head reached the bony outlet, but the pains were very unsatisfactory. At 1.15 P.M. membranes broke; O.R.A.; in last part of labor much delay. I withdrew at this time ether; much improvement following and patient giving courageous help; a well girl, ten and three-quarters pounds, was born at 4.48 P.M. Head large and firm; no tear in perineum; placenta remarkably large. Fl. extract of ergot  $\mathfrak{z}\text{i}$ .

CASE VII. M. H., aged thirty-one; quintipara. First warning of labor at 2 A.M.; annoying pains continued from that time, but there was no dilatation till 4 P.M. Head high; membranes entire; patient has during last month made frequent use of chloral to procure sleep. Last evening she took  $\mathfrak{z}\text{i}$  again at 5 A.M., a third time, at 7 A.M.;  $\mathfrak{z}\text{i}$  was taken at 5.30 P.M.; at 6 P.M. dilation, os size half-dollar piece; very little descent; ether was then moderately exhibited, because of restlessness and impatience; "so weary"; the pains were fairly severe. At 8.15 P.M. well, living girl born; ovum unbroken. After the expulsion of the head I tore open the membranes, being concerned for the child's respiration. There was no nick in perineum; placenta soon. I waited long for the withdrawal of a portion, and I did not feel sure that I wholly removed them. The patient was carefully watched; one hour later, after cautiously moving her for cleansing there was alarming syncope, often repeated. Laudanum  $\mathfrak{z}\text{gr}$ , Brandy  $\mathfrak{z}\text{vi-vij}$ , fl. extr. of ergot by the mouth,  $\mathfrak{z}\text{i}$ ; ice long held over uterus; hot water at feet. The uterus never rose above umbilicus. At times there were troublesome after-pains, with succeeding relaxation; no hæmorrhage. After four hours I administered, at the suggestion of the patient,  $\mathfrak{z}\text{i}$  of Horsford's Acid Phosphate, and refreshing sleep followed. Twelve hours after delivery she passed a coagulum as large as a man's fist, and another small one. The convalescence has been uninterrupted and satisfactory.

I owe the Section an apology for detaining it so long with the report of seven cases of every-day labor. It is true no one of us could narrate seven cases without presenting some peculiarities of individual management that might interest his colleagues; but my real motive for bringing these cases before you has been my interest in those numbered I, III, and VII, as bearing upon the question of anesthesia.

In each instance the woman under my charge was a person widely known in this community. Fatal accident in childbirth is an evil that reaches far beyond the immediate sufferers. In cases I and II, I succeeded in charge of the patient obstetric practitioners of the very highest experience among us. I was warned to avoid the administration of ether.

## Hospital Practice and Clinical Memoranda.

### A CASE OF ERYTHROPSIA.

BY DAVID COGGIN, M.D., SALEM, MASS.

In the *Annales d'Oculistique*, t. xiv, p. 80, is a review of a monograph by Dr. Van Duyse, of Ghent, on red vision after cataract-extraction. The history of two cases is given. Both occurred in females, of the same age, sixty-four years, and a coloboma of the iris was left as the result of the operation in both.

In one patient, red vision appeared in nineteen months after, and it persisted at times for eighteen days, when it disappeared for a year, to return for only a few days. It generally came on at twilight.

In the second case, the patient reported the appearance of the red vision in four months after having had the cataract extracted. Here it came on at bed-time, previous to which the patient had walked along some heights overlooking the sea, where the light was naturally intense. The erythropsia had gone on the following morning, but it returned once or twice during the next six weeks while the patient was travelling.

Two theories have been advanced as to the cause of this phenomenon. One is, that the increased amount of light that enters the eye through the artificially-enlarged pupil over-excites the periphery of the retina and so exhausts it. This fatigue affects first the rays of light that are refracted the most (the peripheral) while the receptive condition for the rays that are the least refracted, the red ones, is prolonged, hence the visual field becomes red. So the red vision is due to a torpor of the retina for the rays of greatest refraction.

The other theory is, that the central nervous system plays an important role in its production, as nervous excitement, violent laughing, and the like, may cause it to appear.

As persons from whom cataracts have been removed are oftentimes not seen again by the ophthalmic surgeon, after they have gone to their homes, the general practitioner living in their midst is much more liable to become cognizant of such visual anomalies as the above than is the operator himself, and it is not improbable that cases of red vision are less rare than has been supposed.

Instances of this form of chromopsia have been reported after cataract operations when the iris was not excised, so the dread possibility of its following a so-called "modified Graefe" operation need not be seriously considered by its advocates.

The literature relating to this curious disorder is at present so meagre that the brief history of the following case may be thought of sufficient interest to be placed upon record:—

October 6, 1881. —Miss X. Age seventy-two years. (Of a family well-known in New England annals). Mature cataract of the right eye, ten years in forming. Cataract immature, left. No ether. Pilocarpin nit. (0.05-0.10) before and after the operation. Corneal flap extended from the upper pupillary border superiorly. A moderated-sized iridectomy. Normal exit of lens, save that the lens-sepal presented between the lips of the wound, and it was readily withdrawn. No loss of vitreous. When the eye was opened, after seven days, it looked well, and the sight was good. Patient discharged from the Hospital on the 21st. A week

later a cyclitis developed which soon subsided. In December, Sn. I was read, though there were opacities in the vitreous. During the next six months Miss X. was kept indoors by sciatica. She read and sewed at will, and later was able to exercise in her garden.

September 14th. (Feeling very well, she went out to drive at 11 A.M., (eleven months after the extraction.) The day was bright, and she said she looked pretty steadily at the various objects that came into view and with absorbing interest and enjoyment till her return at 1 P.M. On leaving her carriage everything around her suddenly took on a dark-pink color, and this red environment continued after she had entered her house, it persisted after the lamps had been lighted — though of a different shade — and this distressing red vision remained unaltered for six days.

Although living but a few blocks away, she delayed consulting me till the 21st. (feeling doubtful, very likely, if she should get any relief?), when the light was less annoying, though all objects still seemed pink. The eye was not inflamed and the sight was better than in December. At the end of another week the erythropsia had entirely disappeared, having faded gradually away.

As the patient has again been confined to her house, it is uncertain whether her trouble will return when she is again subjected to the full light of day.

#### SOME FACTS BEARING ON THE ETIOLOGY OF CARCINOMATOUS DISEASES.

BY G. A. WHEELER, M.D., CASTINE, MAINE.

THE predisposing causes of cancer are stated by nearly all authors who have written about this disease, as unknown. It is usually admitted, however, that all causes which tend to lower the vitality of the system are among the number, and by many there is thought to be a kinship between tuberculous and carcinomatous affections. As phthisis undoubtedly bears a cer-

cancerous, though not actually demonstrated to be such by the microscope, which have occurred within the last eighteen years, in the small village of Castine, Maine, and in a particular part of the town. In fact, nearly all on one particular street, or quite near to it. *The few other cases mentioned, having at some previous time lived on or near this street.*

The soil of this portion of the village is superficially a sandy loam, beneath which is a layer of coarse gravel and still deeper a blue clay. All the drinking water upon the street is extremely hard but no analysis of it has ever been made. The street commences near the summit of a hill about two hundred feet above the level of the ocean and slopes down to the sea. The drainage is excellent.

In the accompanying plan of the village the houses where the cases about to be mentioned occurred, are numbered to correspond with those cases.

1. N. G., male, age about fifty. Lived in the house for many years. No hereditary predisposition known. Occupation, a ship carpenter. Autopsy showed scirrhus of the cardiac orifice of the stomach. Death from starvation.

2. J. N., male, age about fifty. Occupation, ship carpenter. No hereditary predisposition known. Had a tumor of the thigh for which he was admitted to the Massachusetts General Hospital, but for which nothing was done there. He afterwards went to the Boston Homoeopathic Hospital, where he was operated upon, but the tumor returned, and he subsequently died, and the death was reported as from cancer. Had lived in this house for years.

3. Wife of the above. Age about forty-five. She was attended by the writer a few weeks before her death, which was due to malignant disease of the womb.

4. C. C., male. Age about fifty. Merchant. No hereditary tendency. Had occupied the house for years. He was operated upon unsuccessfully by the late Dr. Greene, of Portland, for scirrhus of the rectum.

tain relation to the humidity or dryness of the soil, the query is forced upon us whether carcinoma may not also have a similar relation either to the humidity or to the composition of the soil.

I am led to these reflections by a consideration of the cases of malignant disease which were presumably

5. S. H., female, single. Age sixty-nine. No hereditary tendency. Had occupied the house for years. Had a scirrhus of the breast removed at the Maine General Hospital. Died from constitutional infection. Had also a large abdominal tumor.

6. J. H. N., male. Carpenter. Age about sixty.

Had lived in the house from childhood. His mother is said to have had a "sore" cancer of the face. Autopsy showed scirrhus of the pylorus.

7. B. K., female, widow. Age about fifty-five. Had lived in this house and in town only two years. No hereditary tendency known. Died from carcinoma uteri. Is supposed to have had the disease when she came to town, but this is a matter of doubt. Her sister died in the same house two years later of phthisis.

8. B., female, married. Age about sixty-five. No hereditary tendency. Had an abdominal tumor which from its hard, knobby feel I diagnosed as scirrhus. Had marked cachexia when she died. No autopsy. Had lived in this house for years.

9. D. L., female, married. Age about sixty-five. No hereditary tendency known. Had resided in this house for years. Diagnosis, carcinoma uteri. Was under the charge of Dr. Stevens, now deceased.

10. M. C., female, widow. Age about eighty. No hereditary tendency. Had carcinoma mammae. Had resided in this house for years.

11. F. C., female, married. Age forty-four. Cauliflower excrescence of cervix uteri. Removed by Dr. E. F. Sanger and myself. Disease extended and finally destroyed recto-vaginal septum. No hereditary tendency. Had lived in this house twenty years.

12. G. T., male. Age fifty-five. Trader. Died from a malignant disease affecting the stomach, and probably involving other organs. No autopsy. No hereditary tendency. Had occupied this house for ten or twelve years but had lived in the one opposite 4 and 5, for a still longer period.

13. S. D., female, married. Age about forty-five. No hereditary tendency known. Died from what was diagnosed by her attending physician as carcinoma uteri. She had lived in this house for several years, but had also lived many years in the one marked 5. Had a child die of phthisis.

14. L. W., female, widow. Age thirty-seven. Mother died of heart disease, but had a suspicious tumor of the abdomen. This patient was operated upon by Dr. E. F. Sanger and myself for cauliflower excrescence of cervix uteri. Is still living, but is likely, to succumb to the disease eventually. This patient has lived in this house for many years, but formerly lived two houses from the one marked 6.

According to common report there have been one or two other cases of cancer in this same locality, but I have been unable to verify the fact. I have one patient on hand, however, who resides just above 1, who has had a polypus uteri removed, and who now has a large uterine tumor of some kind, the nature of which is still in doubt, but which I am fearful may prove to be carcinomatous.

The surprising thing about these cases is that they should have been confined to such a limited territory. After a residence of fifteen years in this town I have not known and am unable to learn of any other cases of presumed carcinoma occurring in any other portion of this village, and but few cases have occurred in my practice elsewhere. If there be not some local cause for these cases it is remarkable that they should have occurred where they did.

I am aware that so limited a number of cases can have no great weight towards establishing a local cause, but it seems to me they should have some, and they are given in the hopes of inducing other physicians to pay some attention to the localities in which their cases occur.

## Reports of Societies.

### SUFFOLK DISTRICT MEDICAL SOCIETY. SECTION OF OBSTETRICS AND GYNÆCOLOGY.

ROBERT B. DIXON, M.D., SECRETARY.

NOVEMBER 18, 1885. DR. JAMES R. CHADWICK in the Chair.

DR. W. A. DUNN read a paper entitled

#### HYDATIDIFORM MOLE OF THE UTERUS.<sup>1</sup>

DR. ABBOTT, in opening the debate, said that some years since, he had a case of hydatid mole similar to that reported by Dr. Dunn. When he reached the woman, he found that the mass had come away entire, and consisted of a great number of cysts, varying from the size of a pea to a plum, and in quantity, he should judge, more than a pint. There was no trace of a foetus, and no hæmorrhage followed the delivery. The mass was passed, he believed, early in pregnancy, and there were no bad symptoms before or after the delivery. This was the only case of uterine hydatids he had ever seen.

DR. DOE remarked that he had a case similar to that mentioned by Dr. Abbott. A large mass of cysts, sufficient to fill a six-quart pail, came away at about the seventh month. No foetus was discovered.

DR. A. E. McDONALD mentioned the following case: Mrs. H., aged twenty-five years, multipara; family history good; no syphilis. She came under my care about ten years ago, and was treated with satisfactory results for uterine displacement and chronic endometritis. About a year afterward, she again consulted me, stating that she had not menstruated for a period of four months previously, but was then having slight sanguineous discharge, with occasional pain in the region of the uterus. Her abdomen appeared unusually large for that of a woman in the fourth month of gestation, but I thought she might have made a mistake as to the date of her conception. In view of her condition, I did not deem a critical examination advisable. Rest in the recumbent position was advised, with medicine to relieve pain. I was summoned on the following day, and found her having quite strong expulsive pains at short intervals. My attention was called to the chamber-vessel which she had used a short time before my arrival, and I found in it about a gill of sacculæ attached to each other, and which had come away during one of her expulsive efforts while on the vessel. These sacculæ were about the size of small grapes, and semi-transparent, corresponding somewhat to Good's simile of "White currants floating in red currant juice." My finger, on introducing it into the vagina, came in contact with a large, soft mass, which, to the feel, resembled a recent blood-clot, excepting that it was more spongy. I succeeded in removing the mass in its entirety, and found it to be a true mole of the vesicular or hydatidiform variety. I discovered no trace of a foetus in the mass, that having disappeared in the earlier stages of gestation. The whole quantity which came away would more than fill a pint measure. There was no hæmorrhage to contend with in the case, and the patient made a speedy and perfect recovery. Since then, she has given birth to two healthy children who are now living, aged respectively five and three years.

DR. S. W. DRIVER remarked that during a large

<sup>1</sup> See page 642.

obstetric practice extending over twenty-three years, he had never had a case of false conception, although he had had the usual number of cases of deformed children, and the like.

Dr. J. B. SWIFT stated that a medico-legal interest was attached to these cases, as the vagina was sometimes invaded by true hydatid cysts. Hewitt had reported a case of such kind in a young unmarried woman. The true nature of the case would be determined by a microscopical examination, the echinococci heads, with their characteristic hooklets, being found. McClintock has also shown how, in the case of a widow, or woman living apart from her husband, serious mistakes might be made, as he says, "Hydatids may be retained in utero for many months or years, or a portion only may be expelled, and the residue may throw out a fresh crop of vesicles, to be discharged on a future occasion." (Playfair).

Dr. CHADWICK expressed the same opinion as the former speaker regarding the hooklets in the cysts. He has seen a case of hydatids found in the vagina containing hooklets. Hydatids are common in Germany, and are sometimes found escaping from the uterus into the vagina.

Dr. DUNN, in closing the discussion, said that some features of his case were that there was no rise of temperature, no factor whatever, and uterine exploration revealed no retained cysts.

Dr. E. W. CUSHING read from the *Berliner Klinische Wochenschrift*, a report of Casarean section, after Porro's method, performed in Japan, by Drs. H. Omori and J. Ikeda, formerly students in Germany. It is the first of its kind in Japan, although some ovariectomies have been performed there. The rarity of Casarean section in that country is owing to the fact that osteomalacia is unknown there, and that rickets is very seldom seen.

Koda Uta, twenty-three years old, merchant's wife, the child of healthy and still living parents, was married in her nineteenth year. Periods always regular, painless. Three years ago had a child, and as the delivery was very difficult, operative interference was necessary. After this, it is said that there remained a nearly complete closure of the vagina, which was treated in our Woman's clinic, being gradually, but not completely dilated. The next year she came in for examination in the seventh month of pregnancy.

\*Observation: medium-sized, well-nourished woman, fundus uteri felt about 5 cm. above the navel; child in first head position, heart-tones clearly audible at left of navel. On vaginal examination, there could be felt a tough, electrical, annular stenosis, situated about 3 cm. from the introitus vaginae. We could not introduce the forefinger easily, and the vaginal portion of the cervix could not be touched. Many varices on the inner side of thigh, and in the labia. Pelvic dimensions normal. Nothing else remarkable. With the permission of the mother, who desired to have a living child, the Caesarean section was decided on, but the patient came into the hospital at the last moment. The circumferences of the operation were not the most favorable, since it had to be arranged hurriedly, because some pains had been felt already for seven hours. The operation, performed on the 28th of April, under spray, lasted two hours.

\*The field of operation was thoroughly cleansed with carbolic acid and soap. Incision in the linea alba, running from 1 cm. above the symphysis upwards to 4

cm. above the navel. Next we tried to lift the uterus out of the abdominal cavity, rolling it forwards after Müller's recommendation, but we did not succeed. A profound incision through the uterus opened its cavity, while an assistant pressed the abdominal walls firmly against the uterus with both hands. The fully developed child was seized by the flank, which presented, and easily extracted, but it was already asphyxiated. Then we did everything possible to save it, cleaned the mouth and pharynx, induced artificial respiration, squirted cold water into the face, tried Schulze's method of resuscitation, but alas, in vain. Finally, we performed tracheotomy on the child, since we could not introduce a catheter into the trachea through the pharynx.

\*Then we sucked amniotic fluid out of the trachea, and the child came to life. Meanwhile, a strong ligature had been fastened around the lower segment of the uterus, which was amputated about 2 cm. above it. The umbilical cord had been tied, and the placenta left in place without trying to peel it off.

\*Then a careful cleansing of the peritoneal cavity, although no fluid had run in during the operation. Abdominal incision closed with deep and superficial sutures, and the pedicle fixed in the lower angle of the wound by a clamp. Iodoform sprinkled on the sutures, antiseptic dressing.

\*We were well satisfied with the convalescence, for there occurred neither fever nor pain, although the pulse was over 100 for a long time. At the first change of dressings (after six days), we saw the stump dark and discolored, it already had a bad smell, and was ichorous. It was cleansed, and cauterized with a strong solution of chloride of zinc. On the next day, we found the part lying below the clamp also gangrenous, and as we chanced to pull a little on the eschar with the pincette, the end of the stump, with the clamp, fell off easily, without any injury.

\*The floor of the ulcer was wholly covered with necrotic fragments; it was cleaned, cauterized with zinc chloride, and sprinkled with naphthalin. With joy, we saw on the next day that it was granulating beautifully, and thus the ulcer diminished from day to day, so that we could soon dismiss the patient and her little girl entirely cured."

Dr. J. P. REYNOLDS read a paper entitled

#### EVERY-DAY CASES OF LABOR, WITH SOME REFERENCE TO THE ETHER QUESTION.<sup>2</sup>

Dr. A. L. NORRIS stated that he has used ether freely for years in more than one-half of his obstetric cases. He rarely found any ill consequences therefrom. He considers the woman a little more liable to post-partum hemorrhage, but this does not deter him from administering ether when he feels that it is needed.

Dr. ARBOR said that with him it was not a question of whether one should always or never use ether, but rather that it should be employed with discretion. There is no doubt that uterine pain may be arrested by ether, and it is an important question what relation the administration of this agent bears to post-partum hemorrhage. Excess of ether in the last stage may produce a lax uterus, and hemorrhage in consequence. The most alarming case of post-partum hemorrhage he has ever seen was in the case of a phthisical patient to whom a small amount of ether had been given. It checked the pain so that he

<sup>2</sup> See page 613.

stopped the inhalation, and stimulated freely. The child was still-born, owing to a diseased placenta. There was an alarming hemorrhage, but he did not ascribe it to the use of ether. In another case, which lasted fifty hours, at a time when the use of ether in childbirth was a novelty, a large quantity of ether was given. Forceps were applied and a still-born child was removed; the uterus contracted firmly and there was no hemorrhage. He believes in giving ether to alleviate suffering. If he found that it checked the pains he diminished the amount of ether. In a case of one patient in whom in two successive labors ether arrested uterine contraction, he gave a strong dose of whiskey after suspending the administration of the anæsthetic with a most satisfactory result, the patient bearing the pain bravely and doing her utmost to assist the expulsive action of the uterus.

DR. DOE stated that he is a firm believer in ether. He usually gives it, but in small amounts. Whenever the uterus relaxes he removes the sponge. He has never had but one case of alarming post-partum hemorrhage. In this case ether was given, but for not more than five minutes, for it tended to excite the patient, and he took it away. Later there was post-partum hemorrhage. He thought that if he had not withdrawn the ether that possibly there might not have been any hemorrhage, as the primary nervous excitement which directly preceded the hemorrhage might perhaps have been the exciting cause instead of the ether itself.

DR. C. M. GREEN said he had no prejudice against the use of ether, and used it as he would any other therapeutic agent, according to the indications in each case. He did not give ether necessarily on account of the pain of labor, because he believed that many women were able to bear that pain without injury. Much, of course, depended on the nervous constitution of the patient. He had found chloral hydrate and opium very efficacious in many cases. When he used ether he gave it often in small amounts and prevented profound anæsthesia by allowing the patient to hold the ether cone herself. He had never had a case of post-partum hemorrhage, although he had given ether to women who had flooded after previous labors. Unquestionably ether retards the labor; in fact, he sometimes gives ether for the purpose of so doing.

DR. KINGMAN spoke of a primipara, thirty-seven years old, who was confined two years ago, without ether. The labor was tedious and convalescence slow, the temperature remaining at or above 100° for two weeks. There was no septic disturbance. Last summer she was confined again. She was in somewhat better physical condition but the pains were unsatisfactory. Ether was given for two and one-half hours till delivery. Pains rapidly increased in strength and frequency, necessitating the production of complete anæsthesia as the head was passing the vulva. Though the patient was conscious throughout, except during the last few minutes, yet she felt little pain, and stated afterwards that she had no recollection of what passed after she began inhaling the ether. But four ounces of ether were used during more than two hours of this time. Exhaustion was scarcely remarked and convalescence was rapid.

DR. DRIVER said ether should be used with much care, and in the hands of a practitioner with Dr. Reynolds' experience, much might be gained from its use. One must be careful in the selection of the cases which

require ether. He does not use it unless especially indicated, and in ordinary cases does not use it at all. He uses forceps without ether if the woman is in a suitable condition. If the woman is unruly he gives ether.

A point which had not been brought up, was the effect of ether upon the child. He mentioned a case of a combined hand and foot presentation. Version was done under ether, and the head extracted with difficulty. The child died, and he was satisfied that its blood was saturated with ether. Thirteen months after he attended the woman again, under similar conditions. He did not give ether, but terminated labor with the same difficulty, and saved the child. He thinks he would have saved the first child if ether had not been given. He remarked that he recollected seven other like instances of ether inhalation turning the chance against the child, but time did not suffice to present them.

DR. REYNOLDS, in closing the debate, said ether should be given to prevent suffering, and by so doing, post-partum hemorrhage will be prevented. Any woman who has once had ether will want it again. He wished to express himself as strongly opposed to the statement that ether produces post-partum hemorrhage. When ether is given properly, it is extremely rare that hemorrhage follows its use.

As incidental points in reference to his paper, he said he did not consider it right to let the membranes alone to dilate the perineum, as Goodell advises. It is often difficult to make a diagnosis while the membranes are intact.

For years he has given instruction to be extremely careful in locking forceps. There is rarely any difficulty, and one is not likely to get anything but laceration between the blades, but the cord or anterior lip of the uterus may get caught and torn.

#### AMERICAN PUBLIC HEALTH ASSOCIATION.

In the afternoon a session was held, at which a Committee on State Boards of Health reported through its chairman, Dr. G. P. Conn, of New Hampshire. Since the last meeting, three State Boards had been organized, in Maine, Kansas and Pennsylvania. The report also stated that a conference of State Boards of Health, through a committee had adopted recommendations looking to an annual conference to be held during the session of the Association, also proposing that any conclusions of the conference should be reported to the public by the Secretary through the Standing Committee on State Boards of Health.

#### SECOND DAY.—EVENING SESSION.

At the evening session an admirable paper was presented by Prof. E. M. Hartwell, of Johns Hopkins University entitled the

#### GERMAN SYSTEM OF PHYSICAL EDUCATION.

A historical summary of the system of physical training in Germany was given, followed by a description of its operation as at present conducted in the schools of different grades, both civil and military.

In Berlin, one thirtieth part of the school appropriation is expended in gymnastic teaching. The Germans have introduced their system of gymnastics into the

United States, and an adoption of a similar thorough system for our own schools was counselled.

Dr. O. W. WIGHT, health officer of Detroit, gave an entertaining account of the attempt to

#### DISINFECT THE SEWERS

of the city of Detroit. The substances used for the purpose were the sulphate of iron and sulphur. Of the former, about 75,000 pounds were employed by the Health department and 200,000 pounds by the citizens. Of the latter, several tons were used, the sulphur being put into pails carefully prepared for the purpose, and lowered into the sewers at the manholes, after being lighted.

The principal criticism offered in the discussion which followed, was to the effect that such disinfection can have a temporary influence only, since the disinfectants are rapidly washed away with the sewerage.

One excellent result, however, was noticed, the penetrating odor of the sulphurous acid very quickly made itself manifest in dwellings where defective connections existed with the public sewers.

Dr. BENJAMIN LEE, of Philadelphia, Secretary of the State Board of Health, in his paper entitled

#### THE DEBIT AND CREDIT ACCOUNT OF THE PLYMOUTH EPIDEMIC.

gave an extremely interesting and valuable account of this epidemic, tracing its origin very clearly to an outbreak in a certain house in Philadelphia, whose sanitary arrangements were defective. A man was visiting at this house late in 1884, and contracted typhoid fever there, other persons in the house having had the disease. He returned to his home in Plymouth, Pa., ill, in January 1885, and was sick several weeks.

The town of Plymouth receives its water-supply from a mountain stream, across which several dams have been made for the purpose of collecting the water into reservoirs. The house in which this patient lived was situated between two of these reservoirs and within forty feet of the bank. His excreta during his illness were thrown either upon the snow toward the water supply, or into an outhouse, the contents of which fell upon the surface of the ground. After March 25th, during a thaw the snow melted, and the water from it ran into the reservoir. Ten days afterward, or in the usual time allowed for the incubation of typhoid fever, the epidemic made its appearance among the population supplied with the public water. The conclusion that there was a definite cause was made still more evident by the fact that people obtaining their water from wells were not attacked.

The number of deaths resulting was 111, and the total number of cases over 1,000. The actual pecuniary loss to the population in lost time, expenses of attendance on the sick, and other expenses, were estimated at over \$100,000, and no better argument could have existed for the formation of a State Board of Health of Pennsylvania, which was organized during the following season.

This case is one of peculiar interest to all communities having public water-supplies, as well as to the owners of private wells.

At the morning session of Thursday, the subject of the prohibition of the importation of rags, and of their disinfection, was introduced, and was referred to a special committee for consideration.

Dr. JOHN H. RYAN, secretary of the State Board of Health of Illinois, read a paper entitled

#### MARITIME QUARANTINE FROM THE MOUTH OF THE ST. LAWRENCE TO THE RIO GRANDE.

This paper detailed very minutely the existing condition of quarantine as found by Dr. Rauch in a tour of inspection which he had made during the past year. Defects were carefully pointed out and remedies suggested for existing evils, whereby better and more sufficient protection to the whole country might be secured.

Dr. JOSEPH HOLT, president of the State Board of Health of Louisiana, presented the subject of the

#### SANITARY PROTECTION OF NEW ORLEANS, BOTH MUNICIPAL AND MARITIME.

Dr. Holt spoke in his usual forcible style, and treated of the sewerage of the city, the investigation as to the causes of infectious diseases, and the efficient modes employed by the authorities of New Orleans for their prevention, especially by the disinfection of ships and cargoes as shown by Dr. Holt at the last session of the Association.

He alluded at length to the question of yellow fever prevention, and presented the following resolutions:

*Resolved.* The question of immunity from yellow fever is so intimately connected with the social, industrial and commercial growth of Tennessee, the Southern Atlantic, and the Gulf States of the Union, as to determine the destiny of Memphis, Charleston, Savannah, Pensacola, Mobile, New Orleans and Galveston, and *Whereas:* A large accumulating mass of testimony that the power of protecting the unacclimated against yellow fever has been discovered and proven in the inoculation of the essential germ or cause of the disease by methods distinctly formulated and available, these aforesaid declarations and numerous instances cited in corroboration, emanating from medical scientists at the head of the biographical departments in the highest institutions of learning in Mexico and Brazil, authorized by and bearing the endorsement of their respective governments:

*Resolved.* That we, the representatives of the Boards of Health in the several States of this Union, and we, the officers and members of the American Public Health Association, regarding the question as preeminently a vital issue, as one, in its assumptions, true or false, and, if true, of incalculable worth, surpassing the computation of many millions of dollars, and to the saving of tens of thousands of lives of its own people, that we hereby petition and urge upon both branches of Congress, now assembled, to appoint a commission for the purpose of making a complete investigation of, and reporting after a thorough examination of the methods pursued, their effectiveness in protecting the unacclimated against the yellow-fever infection, together with all associated observations and experiments that may be ascertained.

*Resolved.* That in the aforesaid petition the commission shall be stated to consist of three persons, one of whom shall be of known ability and special attainment in biological research, particularly in the department of microscopic investigation and culture of the essential germ as causative of the infectious and contagious diseases. The other two members of the commission shall be medical men of recognized ability, based upon long and ample experience, competent to give expert consideration to all phases of symptoms and course of yellow fever in any form where in the phenomena of the disease may present itself, whether induced in the course of pestilential invasion or in purposely devised inoculations.

*Resolved.* That this Commission aforesaid shall proceed at the earliest possible moment to Rio de Janeiro as the first field of its labors. Having completed there its work, it shall proceed to Mexico, and, if necessary in the accumulation of testimony, to Panama, Colon and Havana.

*Resolved.* That the sum of \$30,000 be appropriated, or so much thereof as may be actually required to pay the necessary and unavoidable travelling and other expenses, and the salaries of the members of the Commission.

*Resolved.* That the sum of \$5,000 shall be paid as a recompense to each member of the aforesaid Commission.

These resolutions were referred to the Executive Committee.

Dr. S. T. ARMSTRONG, of the Marine Hospital, Service, read a paper on

#### MARITIME SANITATION.

treating of the subject as related to the sailor, the passenger, the cargo, the vessel, and the ports of departure.

Mr. H. LOMB had, on the previous day, reported a resolution which was referred to the Executive Committee, and was now presented by them in the following draft:

The American Public Health Association respectfully recommends to the Commissioner of Statistics and Labor the appointment of one or more expert commissioners, of whose duty it shall be to visit the principal factories and workshops in this country, to examine them carefully with reference to the provisions made in them to insure the safety and health of the employees, and to report on the same, with recommendations.

At three o'clock, the Association proceeded to the Executive Mansion, and called upon President Cleveland.

In the evening, the Committees appointed to report upon and award prizes offered by Mr. Lomb, reported as follows:

For essays on the subject of "Healthy Homes and Foods for the Working Classes." Thirty-six essays presented. A second prize of \$200 was awarded to Victor C. Vaughan, of Ann Arbor, Michigan.

On the subject of "The Sanitary Condition of School-houses and School-life." Twenty essays presented. A second prize of \$200 awarded to Dr. D. F. Lincoln, of Boston, Mass.

On "Disinfection and Individual Prophylaxis against Infectious Diseases." One first prize of \$500 to Dr. George M. Sternberg, U. S. A.

On the "Preventive Causes of Disease, Injury and Death in American Manufactories and Workshops, and the Best Means and Appliances for Preventing and Avoiding Them." Three essays presented. One second prize of \$200 awarded to George H. Ireland, of Springfield, Mass.

At the close of the reports of the Committees, Mr. Lomb was gracefully introduced by the President of the Association, and on motion of Dr. J. S. Billings, Mr. Lomb was unanimously elected a life-member of the Association.

Dr. D. A. SARGENT, of Harvard University, presented the report of the Committee on School Hygiene, in which the subject was treated in its relation to the physical wants of the individual scholar, and also to the hygienic condition of his surrounding.

He suggested that the Committee should be enlarged and that reports from State Boards as to their work in this direction should be requested.

Dr. J. MORRIS, of Baltimore, presented the report of a Committee on the

#### DISPOSAL OF THE DEAD.

The report consisted mainly in a review of the subject, so far as it has made progress during the past few years. Cremation was especially considered from a sanitary standpoint, and while the adoption of this mode of disposal was not counselled "in toto," it was recommended as especially useful in times of great epidemics, and also in war.

The discussion which followed showed a divided opinion as to the possibility of harm arising from the ordinary method of earth-burial.

The recent Massachusetts law was explained as providing efficiently for the examination of such cases as might present any suspicion of violence, or doubtful cause of death.

#### FOURTH DAY.

At the closing session on the morning of Friday, the

Committee on Disinfection of Rags was increased by the addition of Drs. J. H. Raymond, of Brooklyn, and Joseph Holt, of New Orleans. A committee consisting of Drs. Wood, of North Carolina, Abbott, of Massachusetts, and Townsend, of Washington, was appointed to report at the next meeting on the subject of the best modes of collection and preservation of vaccine virus to ensure its purity and efficiency.

A recommendation of the Executive Committee that the Conference of State Boards of Health should be invited to become a section of the Association, was adopted. The Conference held several sessions during the week.

The President announced that Mr. Lomb had offered four additional prizes of \$100, \$75, \$50, and \$25, for the best plans of houses to cost \$600, \$1,000 and \$1,500.

It was voted to appoint a committee of three, with Dr. John S. Billings as chairman, to prepare uniform annual, monthly, and weekly blanks for reporting the mortality of towns, cities, and States.

The Advisory Council recommended that Congress should be urged to appropriate the necessary funds so that the medical corps of the Army and Navy could prosecute investigations as to the causes of infectious diseases. They also endorsed Dr. Holt's recommendation that a commission be appointed to investigate yellow fever in the cities where it originates and prevails as an endemic.

A report having been presented advising stringent regulations in regard to rag disinfection, an animated discussion arose in regard to the subject. It was urged that in Massachusetts, a State employing more rags in paper manufacture than any other State, no case, either of small-pox or of any other infectious disease, had been traced to the use of imported foreign rags; trouble had, however, been experienced from domestic rags. The report was re-committed for further investigation.

The election of officers for the ensuing year then took place, the report of the Advisory Council, which is the nominating committee, being adopted as follows: President, Dr. Henry P. Walcott, of Cambridge, Mass.; First Vice-president, Dr. C. W. Covernton, of Canada; Second Vice-president, Dr. G. B. Thornton, of Memphis, Tenn.; Treasurer, Dr. J. Berrien Lindley, of Nashville, Tenn.; Executive Committee, Dr. Pinkney Thompson, Kentucky; Dr. Henry B. Baker, Lansing, Mich.; Dr. Joseph Holt, New Orleans; Dr. Charles Smart, U. S. A.; Dr. C. N. Hewitt, Minnesota; Dr. H. A. Johnson, of Chicago. These officers were elected by acclamation, and the new President made a brief address of thanks.

The Secretary, Dr. Irving A. Watson, of New Hampshire, holds over, having been elected two years ago for three years. The new Executive comprises, in addition to the gentlemen elected to-day, under the rules of the Association, the present officers and the ex-presidents. The ex-presidents are Dr. Toner, of this city; Dr. Ranch, of Illinois; Dr. Kedzie, of Michigan; Dr. Billings, U. S. A.; Dr. Hunt, of New Jersey; Dr. Gilson, U. S. A. and Dr. Reeves, of West Virginia.

Dr. C. A. LINDSLEY, Secretary of the State Board of Health of Connecticut, gave an account of the

#### EPIDEMIC OF TYPHOID FEVER AT MADISON, CONN.

Dr. T. F. WOOD, of North Carolina, contributed a paper on the

## CAPE FEAR RIVER AS A SOURCE OF WATER-SUPPLY.

GEORGE N. BELL, C. E., of Newport, R. I., read a paper entitled

## THE HYGIENE OF THE DWELLING.

Captain H. Lomb, in a brief speech, modestly thanked the Association for their good will and the honors which they had conferred upon him at this session in electing him to life-membership.

At this session of the Association, a delegation was present from the British Provinces, all of whom manifested a lively interest in the work of the Association, were in turn cordially admitted to a participation in all its privileges. One of their number was elected its Vice-president, and others were made members of its Advisory Council.

It was also decided to hold the next session at Toronto, and Dr. P. H. Bryce, of that city, was appointed as chairman of the local committee of arrangements.

## RHODE ISLAND MEDICAL SOCIETY.

EIGHTY-FIVE Fellows attended the regular quarterly meeting in Providence, December 17th, 1885.

The committee appointed at a previous meeting to consider the communication of the American Medical Association in reference to State regulation of the practice of medicine, reported "That although we believe that an act to regulate the practice of medicine would prove of very great value to the citizens of this State, and, if presented in proper form, would be readily adopted by their representatives in legislature, we do not believe that the act referred to us is well adapted for the purpose. Not only is the proposed act lengthy and cumbersome, but it would establish a new branch of the State government, and, on this account alone, would be sure to meet with strong opposition. It would, in our opinion, be a much better plan, as well as more feasible, to place the licensing power in the hands of the State Board of Health, making such changes in the constitution of this Board as might be necessary." The report was accepted, and the committee discharged.

Delegates to other State Medical Societies for the ensuing year were appointed as follows: Maine Medical Association, Drs. A. D. Weeks and W. H. Traver; New Hampshire Medical Society, Drs. W. F. Hutchinson and G. W. Jencks; Vermont Medical Society, Drs. E. M. Snow and W. R. White; Massachusetts Medical Society, Drs. E. T. Caswell and W. F. Morrison; Connecticut Medical Society, Drs. A. G. Browning and W. H. Palmer; New York State Medical Society, Drs. Charles O'Leary and Albert Potter; New York State Medical Association, Drs. S. W. Francis and J. H. Morgan; Medical Society of New Jersey, Drs. F. B. Fuller and C. H. Fisher.

The President appointed Drs. G. W. Carr, F. B. Fuller, J. W. Mitchell, R. E. Noyes and Charles O'Leary as the new Board of Examiners, to whom applicants for membership will hereafter be referred.

In accordance with the recommendation of the Board of Censors, Dr. Horatio R. Storer, of Newport, was admitted to the Society.

Dr. W. F. MORRISON reported a case of

## PYELOPHIBITIS, WITH RENAL CALCULI,

and exhibited the kidney, carefully mounted, with the

concretions *in situ*. The patient, a married American woman, forty-four years of age, came under observation eight months ago, complaining of anorexia, epigastric pain, persistent vomiting, occasional diarrhoea, and severe pain over the region of the right kidney. Micturition at times painful and difficult; urine usually abundant, and contained a thick, stringy white sediment. For a year there had been oedema of the lower extremities and abdomen. An ill-defined tumor was found in the right lumbar region, but no fluctuation detected. The urine contained about one-half per cent. of albumen, numerous fatty cells, and hyaline granula and fatty casts.

She was treated with alkalies, compound syrup of hypophosphites, iron and opiates, and gained in health and strength until about one week before death, when a cold was followed by alarming symptoms. She developed general numbness, pricking sensations in the shoulders and extremities, vomiting and constipation; no headache; strabismus, twitching of the muscles, delirium and stertorous respiration followed, and she died comatose. Suppression of urine during the last twenty-four hours.

Autopsy, fourteen hours after death, showed chronic cystitis, and parenchymatous and amyloid degeneration of the left kidney. The right ureter was enlarged about four times its normal size, and terminated above in a firm pear-shaped tumor, which was everywhere adherent to surrounding parts. On section, it was found to contain half a dozen pouches or sacs, about the size of English walnuts. These cavities apparently converged to the pelvis of the kidney, and contained inoffensive pus and granular detritus. The quantity of pus was estimated at four ounces. Three of the pouches contained each a calculus, irregular in size and shape. The three measured in length, respectively, two, one and three-quarters, and one and one-half inches.

A paper by Dr. F. P. CAPRON, on

## NASAL CATARRH—ITS IMMEDIATE AND REMOTE EFFECTS,

was read by title and referred to the publishing committee.

Dr. GEORGE F. KEENE read a paper on the

## TREATMENT OF COLLES' FRACTURE BY A NEW METHOD,

which consists in putting up the fracture with the hand extended nearly to a right angle with the arm, and supported by a wire splint. If the forearm is placed on a flat splint so that the fingers are flexed over the end, it will be noticed that the radius does not touch the splint at all, and the ulna only on its upper third. If, however, the hand is lifted until fully extended, the radius will touch the splint at its lower end, the thenar and hypothenar eminences of the hand being lifted out of the way. The flexors act at their best advantage when the hand is thus extended; and regain flexibility and strength rapidly when the splint is removed. When the hand is clenched, it moves quite perceptibly to the ulna side of the arm. In the treatment of this fracture, the flexor muscles should be placed at their best advantage, the extensor muscles should be placed at their greatest disadvantage, and the end of the radius should be brought down upon the splint.

To accomplish these ends it is only necessary to

bend a piece of ordinary telegraph wire, first into the shape of an ordinary hair-pin, then bend up sharply about two and a half inches of the closed end, flattening somewhat the top of the bend so that the fingers may rest easily upon it at their articulation with the hand. The ends of the wire are fastened with a strip of tin curved to fit the arm, and with a second strip under the end of the radius.

Dr. KEENE reported three cases in which his splint fulfilled all the conditions of success, avoiding pain and swelling during treatment and preventing subsequent deformity and impaired function of the hand and forearm.

Dr. O. C. WIGGIN read a paper on

#### THERMIC FEVER, WITH REPORT OF THREE CASES.

The cause of sunstroke is not necessarily solar heat, but heat always. The predisposing causes may be summed up in all previous conditions which have tended to debility or undue exhaustion. In a large proportion of cases there is abundant warning of an approaching attack. The most uniform premonitory symptoms are lassitude, feeling of fullness and pain in the head, throbbing of the temples, dizziness, discomfort at the precordia, loss of appetite, nausea, thirst, palpitation, and scanty urine. The prostration, head symptoms and palpitation increase in violence up to the time the patient is lost in insensibility.

Treatment varies considerably accordingly as the heart or the nerve centres are more profoundly impressed. Spasmodic contraction of the heart seems to be the immediate cause of speedily fatal cases. In these cases there is absence of high temperature and consciousness is not impaired until the sudden dissolution, the skin is at first cool and moist, feet and hands cold, countenance pale and anxious, nose cold and studded with beads of sweat. Symptoms of distress are referable to the heart. Indications in these cases are plainly to restore the action of the heart and the capillary circulation. Hot, and not cold, applications are to be applied to the skin. Stimulants in form of ammonia valerianate, strong tea, and morphia in small doses. Chloroform is unquestionably the salvation of some cases, and it would be of many more, could it be brought into timely use, but unfortunately the heart has ceased to beat, has solidified, so to speak, before aid is forthcoming.

In those cases in which symptoms referable to the brain and spinal cord predominate, cold applications to the entire body are demanded, and are the first remedial agents to be thought of. The vaso-motor nerves are paralyzed. The rise of temperature is rapid and extreme. The excretory functions are nearly in abeyance. Temperature must be reduced as speedily as possible.

Alcohol is seldom required in treating sunstroke. Ammonia valerianate is evanescent in effects, but its action is speedy and unequivocal. Tea is the remedy *par excellence* for sustaining the heart's action. Moreover, if there is a legitimate use of tea as a beverage it is during hot weather. Opium in some form is of service in the painful symptoms of sunstroke. Leeches or the lancet are indicated in cases of extreme congestion of the brain.

The vaso-motor paralysis, which obtains in thermic fever, necessarily leads to a more or less engorged state of the vital organs. The lungs, next to the brain, are the most frequent seat of congestion. It is sometimes

startling to notice the shortness of the interval between the stroke and marked dullness and rales.

Passive congestion of meninges is a common occurrence among convalescent patients. Inability to endure heat for a long time after insolation is almost a constant sequela. The victim of sunstroke but rarely recovers the former standard of health.

The president announced the death of Dr. John W. Sawyer, Superintendent of Butler Hospital for the Insane, and a Vice-President of the Society, and appointed Drs. Storer, Ely and Batchelder a committee to frame resolutions, which were adopted as follows:

*Whereas*, An inscrutable Providence, who wounds only that through His own mysterious reasons He may really benefit, has taken from the Rhode Island Medical Society its beloved Vice-President, Dr. John Woodbury Sawyer, therefore,

*Resolved*, That in Dr. Sawyer not only had the Butler Hospital a medical superintendent whose first and only thought was the welfare of the unfortunates whom it was his duty to protect, to care for and to heal, but a judicious adviser, who added much to its previous reputation as a model institution.

*Resolved*, That the loss of Dr. Sawyer is one equally great to the city of his residence and to the State at large, so many of whose citizens have had occasion to require his kindly skill.

*Resolved*, That the Rhode Island Medical Society mourns its deceased brother, whose mere acquaintance was a pleasure, and whom to know was to love. Gentle and yet decided, modest always and wholly forgetful of self, learned in his special department of professional labor, and yet inferior to none as a general practitioner, his death leaves a void which time can never more than imperfectly fill.

*Resolved*, That the President and Secretary in behalf of every member, tender to the bereaved widow and orphaned son of the deceased their sincere and heart-felt condolence, and their sense not only of collective but of personal bereavement.

*Resolved*, That a committee be appointed by the chair, to attend the funeral of Dr. Sawyer in behalf of this Society, as an additional mark of sympathy and respect.

### Recent Literature.

*Clinical Therapeutics.* Lectures in Practical Medicine, delivered in the Hospital St. Antoine, Paris, France, by Professor DUJARDIN-BEAUMETZ, Physician to the Cochin Hospital, Member of the Academy of Medicine, and of the Council of Hygiene and Sanibility of the Seine. The Treatment of Nervous Diseases, of General Diseases, and of Fevers. Translated by E. P. Hurd, M.D., Member of the Massachusetts Medical Society, Vice-president of the Essex North Medical Society; one of the physicians to the Anna Jacques Hospital, Newburyport, Mass. Detroit, Mich.: George S. Davis, 1885.

This volume is a translation of Volume III of the excellent *Leçons de Clinique Thérapeutique*, by Professor Dujardin-Beaumetz, and deserves warm commendation. From the outline of the author's many works, which the translator gives in his preface, one may readily see the wide range of the author's experience and the translator's full sympathy with his author and his appreciation of the highest aims in therapeutics.

The introductory lecture on clinical therapeutics has many good suggestions. In therapeutics "there are two dangerous rocks to shun, skepticism, on the one hand, exaggerated enthusiasm, on the other, to believe too much, and not to believe at all, are two opposite terms, but they are not as far apart as one might suppose. The one engenders the other, and extreme credulity gives rise to incredulity.

"Beware especially of skepticism; a physician who lacks faith in medicine has no more reason for existence than a priest who does not believe the religion he teaches, or a soldier who is destitute of love of his country and his flag. It is repugnant to reason and to conscience that he can be a good physician who judges of no utility all the remedial agents that have the sanction of tradition and custom."

Of experimental therapeutics he says, "it is indeed an excellent study which has furnished valuable data, but do not forget that it is only a complimentary study. It enables us to give a tolerably plausible explanation of the action of the medicament, and especially to know the limits beyond which it is not safe to go, and at what moment the drug ceases to become medicinal and becomes a poison. But it is not physiological experimentation that decides the destination of the medicament, or of medication; it is the effect of the remedy on the sick man, and on the march of the disease which determines its therapeutical value." He also indicates the serious consequences which are the result of the practitioner's ignorance of the art of prescribing. "Exercise the greatest care in the directions which you give the patient or his nurses; do not fear to enter into the minutest details; indicate how the external applications should be made, and the times for giving the internal remedy; regulate carefully the little incidents of the day, and be particular about the diet. For you must ever remember that pharmaceutical measures go but a little ways in the cure of your patient, and that you can often accomplish more by hygiene than you can accomplish by medicine." "Hygiene is, in fact, called upon to play a preponderating part in the treatment of diseases, and especially of chronic affections. To establish with care, and, in a scientific manner the basis of dietetics, ought to be one of the most serious occupations of the practitioner, and you will see in the course of these lectures the prominence which I give to hygiene in the treatment of diseases."

Following the introduction are chapters upon diseases of the nervous system, the first of which is devoted to the physiology of the nervous system, afterward lectures upon various kinds of treatment, hydrotherapeutics, medical electricity, and a chapter on the techniques of electrical machines in which the most modern forms of apparatus are described by Dr. C. L. Dana, of New York.

The lectures on the treatment of neuralgia, of hysteria, epilepsy, chorea, meningitis, as well as on apoplexy and chronic myelitis, all contain valuable suggestions, and discuss these diseases from a clinical therapeutic standpoint. The second part of the work is devoted to the study of blood, to blood-letting and the treatment of anæmia; rheumatism, diabetes, and syphilis are also included in the other half of this part.

In the third division of the book, which is devoted to fevers, typhoid fever, intermittent and the eruptive fevers are considered.

The translation leaves nothing to be desired; the

reader is not conscious that the subject has been rendered from another language into English. Dr. Hurd has also added some short notes in a very judicious manner. That the work is rather too rich in suggestions for treatment will not surprise those who are familiar with the author's many other writings. In these days of superabundant medicaments an undue zeal for new remedies may not easily be avoided.

Much that is of little service to a practitioner in many of the text-books on therapeutics has been left out, and on the other hand, whatever in anatomy or physiology, or other department of medicine that might be of assistance in the treatment of disease has been grouped in so practical a way as to give a rational conception of the means and methods of therapeutic usefulness.

So good a book had deserved a better dress, but if its cheaper covering brings it within the means of a larger number of practitioners it is certainly justifiable.

*Lectures on the Diagnosis of Diseases of the Brain, delivered at University College Hospital.* By W. R. GOWERS, M.D., F.R.C.P. Philadelphia: P. Blakiston, Son & Co. pp. viii, 246. 1885.

It is a satisfaction to have this volume from Dr. Gowers; it will be of value to those who desire to study the various diseases of the brain. As there is a wider range of opinions in regard to the physiology and pathology of the brain than of the spinal cord, it is not to be expected that every one would agree with all that the author has written. The views expressed are, however, those of a competent observer who has had large opportunities to study the subject, and what he has written is valuable, and will prove a useful guide to all in further study of the subjects.

The first three chapters are devoted to the anatomy of the brain; these are full, but condensed, and will require careful study to be understood. A larger number of diagrams and drawings would aid the student to a better or more speedy understanding of these chapters.

Chapters IV to XII are devoted to a consideration of the symptoms produced by disease, the mechanism of their production, the motor and sensory symptom, those due to perverted function in the cranial nerves, mental symptoms, affections of speech. Among these, two of the most difficult subjects are the ocular and visual symptoms and the affections of speech. These are treated at length, so as to give a satisfactory review of the subjects, without using time and space to discuss the opinions of others. The author has given his own conclusions.

In speaking of disturbance of speech, he says, "No two cases of speech defect are alike; and you can only unravel the phenomena of each case by having a firm grasp of the laws that govern both normal speech and the derangement that is produced by disease."

The multiplication of names applied to various forms of aphasia is justly condemned. The terms amnesic aphasia, ataxic aphasia, word deafness and word blindness are used, but seemingly only partially approved. Wernicke's division — motor and sensory aphasia — is more acceptable to the author, but Wernicke is not fully followed. Hughlings Jackson's views find more favor than Kissmaul's.

Chapters XIII and XIV on local diagnosis, are very satisfactory and full. The book closes with diagnostic pathology and pathological diagnosis.

One cannot skim through this book and receive much benefit; not merely careful reading will answer; it must be carefully studied from beginning to end, and then its value will be appreciated. In the closing paragraph, Dr. Gowers says, "The problems that we have considered in these lectures are certain to present themselves before you frequently in your future work. Their form will vary, but the principles of diagnosis that I have endeavored to put before you will guide you, I believe, to a right conclusion in most cases. When you meet with special difficulty, do not be hasty in trying to arrive at a decision; think over the symptoms; read over the description of the diseases between which the diagnosis lies; examine your patient again, and, if necessary, watch the symptoms for a time." This is excellent advice.

**Practical Therapeutics.** A Compendium of Selected Formulae and Practical Hints on Treatment, Systematically arranged, interleaved, and copiously indexed. By EDWARD J. BERMINGHAM, A.M., M.D., Fellow and ex-Vice-president of the American Academy of Medicine, etc., etc. New York: J. R. Bermingham, publisher. 1885.

In a book of two hundred well-printed pages, which are interleaved, there are collected and arranged according to the diseases in which they may be employed, a large number of prescriptions, with here and there brief notes on the treatment of the disease under consideration. The name of a practitioner is in most cases appended to each prescription.

For those who are simply looking for a prescription to copy, being too ignorant to write one, this book is hardly needed, as a sufficient number of formulae may be found in the numerous works on therapeutics, of which some are in the hands of every practitioner.

It is too brief to be accepted as a guide in the treatment of disease, and as a work on prescription-writing, it encourages the ignorance which is already too widespread among medical men. Of many good and old prescriptions some are, and others should be, sanctioned by the pharmacopœia, and beyond this, practitioners should be able to rely on a simple, extemporaneous prescription, written so far as possible with a distinct and special object, and based upon a knowledge of the physical, chemical and therapeutic properties of the substances used. A work such as the one under consideration, helps to keep the physician away from an independent and intelligent use of drugs.

**A Manual of Operative Surgery.** By LEWIS A. STIMSON, B.A., M.D., Surgeon to the Presbyterian and Bellevue Hospitals, Professor of Clinical Surgery in the Medical Faculty of the University of the City of New York, etc. Second edition, with 312 illustrations. Philadelphia: Lea Brothers & Co. 1885.

This comprehensive little manual of some five hundred pages, has attained a second edition within about a year and a half of the appearance of the first, which fact speaks well for the success of the work in meeting a want of practitioners and students. In this new edition special reference is made to the changes in operative methods and procedures by the adoption of the antiseptic method of treating wounds. In the descriptions of the formal operations, the chief alterations and additions are found in the passages treating of the excision of joints and bones, and of operations in which the peritoneal cavity is opened.

**A Treatise on Epidemic Cholera, and Allied Diseases.** By A. B. PALMER, M.D., LL.D. pp 224. Ann Arbor, Michigan: Register Publishing House. 1885.

**Cholera, its History, Cause and Prevention.** By EZRA A. BARTLETT, M.D. pp. 105. Albany, New York: H. H. Bender. 1885.

Dr. Palmer has briefly sketched the history of cholera, and also in the same chapter has reviewed the subject of its etiology, introducing abundant references to the most recent investigations of European authorities made during the epidemic of the past two seasons.

The remaining chapters are devoted to the symptomatology and pathology of the disease, its diagnosis, prognosis and prophylaxis, and finally its treatment, in regard to which the author draws largely from his own experience in early epidemics of the disease. The chapter on prophylaxis is especially valuable, and quotes freely from the recent circulars of State Boards of Health, especially that of Michigan.

A second part is devoted to the subject of choleraïd, or allied diseases.

Dr. Bartlett's book was written, as he states in his preface, for the people, an attempt being made to set before them "in an unpretentious manner the latest, and best opinions." This he has successfully accomplished, the book being written in a popular style, and issued in a compact and convenient form.

The chapters are entitled: History, cause, propagation, prevention, hygiene of food and drink, and disinfection.

The subjects of propagation and prevention are clearly and intelligently stated, but that relating to food and drink is treated in a manner somewhat foreign to the general subject of the book.

**Diseases of the Tongue.** By HENRY T. BUTLIN, F.R.C.S. Assistant-Surgeon and Demonstrator of Practical Surgery and Diseases of the Larynx, St. Bartholomew's Hospital. Illustrated with chromo-lithographs and engravings. Philadelphia: Lea Brothers & Co. 1885.

This is one of the "Clinical Manuals for Practitioners and Students of Medicine." The author discusses the various diseases of the tongue in a thorough manner, and lays down very positive rules in regard to treatment. The application of strong caustics to warty growths or indolent sores of the tongue is strongly condemned. He states that "if there is one means more certain than another to transform a simple into a cancerous sore, it is the use of caustic." The disease must be removed by the knife; the actual or galvano-cautery, or treated with applications as unirritating as possible. When weak astringent lotions are needed, alum, tannic acid, and sulphate of zinc may be used, but chromic acid, five or ten grains to the ounce, is believed to be the best of all. The subject of cancer, and the different operations for removal of the tongue are considered in detail.

It is said that illustrations to be of value ought to be read as easily as the text. We think the excellent chromo-lithographs in this volume will bear this test. Mr. Butlin's book is an important addition to surgical literature, not only on account of its intrinsic merit, but also because it treats of the affections of an organ that has been too much neglected.

# Medical and Surgical Journal.

THURSDAY, DECEMBER 24, 1885.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly, by CUPPLES, UPHAM & Co., Boston. Price, 15 cents a number; \$5.00 a year, including postage, to subscribers in the United States and Canada. Foreign subscribers are charged the postage in addition.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.*

CUPPLES, UPHAM & COMPANY,

2-3 WASHINGTON STREET, BOSTON, MASS.

## FEWER DRUGS.

THE part drugs play in the cure of disease and of the patient — for these are not always the same — is thought by some to be very great, while by others it is held to be next to nothing. Between these two extremes may be found all shades of belief and skepticism; as usual, the truth lies somewhere between these limits, and every practitioner would assign himself a place somewhat different from the one which would be chosen by his colleagues.

That there are drugs which, under proper conditions and with intelligent direction, may be made very serviceable, only those ignorant of their use will deny. That opium, ether, mercury, quinine, digitalis, nitrate of amyl, iron, certain of the cathartics and other remedies may be made to serve useful ends, there is abundant testimony to prove. Why does it so frequently happen that some of these are not intelligently employed and that the wholesale condemnation of drugs is so frequently heard? One reason, among others, may perhaps be found in the fact that the really valuable drugs have to cover the incapacity of numerous inefficient associates, and there is not time for every practitioner to go carefully through the bushel of chaff.

Does it not then become one of the duties of those members of the profession who interest themselves in this side of medicine, to clear out the worthless and doubtful things which encumber our materia medica, and thus bring the better agents more easily within the reach of the practitioner?

It will be urged that there are many remedies considered valuable by some of the profession, which would be discarded by others under those circumstances; let us give ourselves the benefit of the doubt, by getting rid of all such as have not an established reputation. We have an official list of drugs and preparations, including several hundred titles; it is called a pharmacopœia, and although a large number of practitioners are quite innocent of a knowledge of its contents, and there are some to whose ears the name even is foreign, it would seem to offer one means of attacking the problem under discussion. It would not be im-

possible to form a collection of higher average worth than the present pharmacopœia, by eliminating redundant and useless drugs and preparations and adding a very few others. Something of this nature might well be done at the next revision of this book, if physicians would take greater interest in what is already one of the best works of its kind. Let it be recognized, in doing this, that the profession would be better off if they had pointed out to them one or two good remedial agents which they should learn to know intimately, than they now are with a larger number of which they know but little.

Of the great mass of preparations and compounds of uncertain or unknown strength or composition not included in the pharmacopœia, nothing need be said to the readers of this Journal.

We are already sufficiently advanced in therapeutics to be able to substantiate by the experience of many years, or by combined experimental and clinical evidence, the claims of a number of good medicines, and to be able to throw away those unable to show a certificate of respectability.

Nor have we to consider only the older useless drugs; there are a multitude of new ones, or old ones under new combinations, which clamor for attention in the medical journals, or for money in the advertising columns of the medical and daily papers. As regards the former class of new remedies, it would be well for the practitioner to resist the temptation to try every new thing which he reads of, and to accept only those which bring reliable evidence of clinical or physiological worth; and by this is meant something more than a report of one or two successful cases, or an account of a few experiments on animals. So far as the majority of practitioners are concerned, it would in nearly all instances be better to consider all new remedies as worthless until they are forced to admit their value, rather than be too ready to welcome all the drugs which are brought to their notice; and they should recognize that they have not, as a rule, the opportunity or the training necessary to form a just estimate of the merits of most of these novelties, any more than they have time to investigate their physiological action, if this were worth the while. Could we possess in the pharmacopœia a shorter list of higher average merit, it would be possible for physicians to have a more intimate acquaintance with the properties of official drugs, and later of their actions, and not acquire the habit of using too great a variety of remedies carelessly, and thereby learning to believe in too many, or to disbelieve in all.

The reduction in the number of official remedies would not be unacceptable to the pharmacist, who would be required to keep fewer of the drugs which are so seldom employed that they deteriorate before they are sold, and thus, with a smaller number, could afford to have a better quality.

After fewer and better drugs are employed, not only their properties but their action will be more easily kept in mind, and they may be used with greater discrimination and success.

We are tempted to add a word about giving medicines, although this relates to their action as well as to their properties. In many cases a good and sufficient reason for giving a prescription is to help the patient follow accompanying directions about diet or exercise, or to shield the patient from his own or his friends' sometimes absurd whims or advice. Under other circumstances it should be appreciated that more is expected than to prescribe digitalis in every case of rapid pulse, or to give a full dose of opium for every pain; and let us be more familiar with the properties of drugs than to dress a wound with crystals of carbolic acid.

#### THE INFECTIOUS CHARACTER OF GLEET.

At the recent meeting of the German naturalists and physicians, Neisser of Breslau, the discoverer of the gonococcus of gonorrhœa, spoke of the infectiousness of gleet. The urethral discharges known under the name of chronic gonorrhœa, while being always the result of a primary blennorrhagia, may be infectious or not infectious, as is determined by the presence or absence of the gonococcus. The examination, said Neisser, should be repeated for several days in succession, because the gonococcus, almost always few in numbers, may be wanting at the first examination, while it may be found at a second or third.

The true gonococcus cannot be cultivated on gelatine or agar-agar, a characteristic which distinguishes it from other diplococci existing sometimes in the urethra. The true gonococcus is cultivated in the serum of blood, and on potatoes.

Neisser has examined 113 cases of chronic gonorrhœa (duration of the disease from one to eight years), and in 80 cases he has found the gonococcus; in 63 the result was negative. Neisser's conclusions are as follows:

Every case of chronic blennorrhagia ought to be examined relatively to the presence or absence of gonococci.

Cases of chronic urethritis, complicated with alterations more or less grave of the mucous membrane, (erosions, ulcerations, papillomata), require *always* a treatment directed especially to the relief of such pathological conditions, irrespective of the presence or absence of the gonococcus.

In cases where there exists no marked structural changes in the walls of the urethra, the first question to ask, is, whether gonococci are present or not. If they cannot be found, and there are no subjective or objective symptoms of alarming nature, Neisser would abstain from all active interference, for on the one hand, the treatment, no matter what, remains almost always inefficacious, and on the other hand, these urethritides, *not complicated and non-infectious*, persist, often for years, without any troublesome sequel (sic). When on the other hand, there are gonococci present, it is necessary to treat the gleet. The best remedial application is that whose parasitical effect is the most certain, and which, at the same time, irritates the mucous membrane the least.

After numerous trials, Neisser prefers irrigations, with a solution of nitrate of silver. 1 part to 2,000, by means of an elastic catheter, with several openings near the end; these irrigations, he continues till the complete disappearance of the gonococcus. Sometimes considerable perseverance is necessary. It is a mistake to suppose that any *heroic* treatment can more speedily effect a cure; all the art of the practitioner consists in judiciously combining, if necessary, the treatment directed against the gonococcus with that of any structural changes which may exist in the mucous membrane. The internal use of copaiba is a good adjuvant, because its derivations, excreted by the urine, are anti-bacteric, and prevent decomposition of the urine, an important quality in view of a cystitis always possible, and this especially after long continued catheterization.

There seems to be much evidence in favor of regarding the specific nature of the so-called gonococcus, as the essential factor in giving rise to contagious qualities in any urethral or other discharge, but as to its diagnostic value, it should be borne in mind that, according to the most complete investigations, recognition of the gonococcus is not possible merely from observation of its size, shape, and reaction to staining agents.

The following are the statements of Bumm, with regard to this practical point, in his recent work on the gonococcus (*Der Mikroorganismus der Gonorrhoeischen Schleimhaut-erkrankungen*, etc., etc., Dr. Ernst Bumm, Wiesbaden, 1885, Verlag von J. F. Bergmann).

The diplococcus form of arrangement, as well as the biscuit shape, are not characteristic of the gonococcus. Neither is the size any criterion of its nature, for not only does the gonococcus itself vary in dimensions, but there also exist other diplococci of the same size as well as shape. With one exception, all the six varieties of biscuit-formed diplococcus, thus far detected in various secretions, and distinguished from the gonococcus by difference of behavior while under artificial cultivation, manifest the same reaction to coloring matters as does the latter.

The striking difference, however, between gonococcus and all other recognized varieties of diplococcus lies in the fact that to the former alone belongs the power of penetrating into living cell protoplasm, within which they are to be seen grouped around the cell nucleus. So far as Bumm's researches have shown, no other similar diplococcus is found to do this, and, therefore, it follows that reliance can be placed only upon the discovery of diplococci which may be incorporated in cells as showing that any secretion is of gonorrhœal nature, and, in consequence, contagious.

#### THE MASSACHUSETTS HEALTH REPORT.

THE health supplement to the sixth annual report of the Massachusetts State Board of Health, Lunacy, and Charity is a volume of nearly four hundred pages, containing the reports of the analysts of drugs and medicines; the summary of weekly mortality returns; the condensed replies of correspondents regarding the

health of towns; papers embodying the results of investigations into the sanitary condition of school-houses and the comparative safety of illuminating gases; the health officer's notes on disinfection and epidemic cholera; and a short paper by Dr. Jones on the "Sanitary Relations of Taunton."

Dr. David F. Lincoln examined 173 schools in 25 cities and towns, and reports at length regarding the sanitary questions suggested by his inquiry, giving 22 plans of schools. His well-known reputation in school hygiene is fully maintained in a careful paper of 92 pages, which we will not attempt to condense, but which we advise our readers to consult for themselves. He shows scientifically how we are sinning towards our children by what Hosea Biglow less elegantly calls "overloading their underpinning."

The exhaustive report on illuminating gas should settle the question of the introduction of water-gas for illumination of houses. The researches of Professor Sedgwick and Professor Nichols indicate that the average percentage of carbonic oxide (the dangerous component of illuminating gas) in coal gas examined from cities and towns in this State in 1884 was 5.53 (limits 3.19 and 6.74) and in water-gas 27.46 (limits 24.47 and 31.52). Their experiments on animals proved its great danger to life, and Dr. Abbott shows that during the years 1865-1877, when water-gas was scarcely used, the annual number of deaths from asphyxia by illuminating gas in cities of the United States was 2+, but in the years 1878-1885, after its introduction, 12+. A similar difference existed between Boston and Baltimore. In Boston, where water-gas is not used, there were four deaths in twenty years, in Baltimore 19, of which 17 occurred in the last three years since the introduction of water-gas for illuminating dwellings.

The one hundred and fifteen pages devoted to the consideration of the laws regarding the adulteration of food, including milk, and of drugs, deal with the reports of a year's doings in that part of the work of the health department which is probably its most useful function at the present time. A general idea of the benefits to the community may be reached from the facts that there were 48 prosecutions during the year, of which all but three were for adulteration of milk, and that 433 warnings were issued to persons selling adulterated articles.

The comparative statement of the mortality in different cities, the notes on disinfection and cholera and the health of towns present many features of interest which may be profitably studied by every local health board in the State.

#### CONTAGIOUS OPHTHALMIA IN NEW YORK SCHOOLS.

DR. RICHARD DERRY recently addressed a communication to the New York Board of Health, in reference to the prevalence of contagious ophthalmia in schools and asylums, in which he gave a report of the action of the New York Academy of Medicine last

spring in appointing a committee to suggest and carry out measures for the efficient control of the disease, and requested that some twenty-five physicians, who had been selected to visit the various institutions, should be appointed sanitary inspectors without pay.

At the last meeting of the Board, Colonel Prentice, counsel to the Board, sent in an opinion on the request of the committee, in which he stated that the appointment of special sanitary inspectors, without pay, would not be proper, and suggested that regular sanitary inspectors should be detailed to accompany the physicians selected, so that the investigation and its results could be reported to the Board. A resolution directing the Sanitary Superintendent to detail two inspectors to accompany the physicians was accordingly adopted.

An energetic effort will be made to have a law passed during the coming session of the New York Legislature which will require an ophthalmic examination of every child entering an institution, and that any affected child shall be kept in quarantine until its eyes are cured.

#### MEDICAL NOTES.

— Prof. A. D. Grinnell, M.D., of the University of Vermont, will give the course of lectures on the Practice of Medicine, at the Long Island College Hospital, the ensuing year.

— The talk of the day: Mrs. A. — "I hear that the Montmacksingtons are going to spend the winter in Paris." Mrs. B. — "Indeed? You surprise me! When were they bitten?" — *Boston Transcript*.

— J. B. Bailliére died in Paris on the 8th of November. He was the oldest, and one of the most widely-known of the French medical publishers and booksellers. He was eighty-eight years old, and continued in active business up to his death. He had many warm friends in the medical profession.

— The first number of the *New Yorker Medizinische Presse, Organ der Deutsch-Amerikanischen Aerzte*, has reached us, under date of December, 1885. It is the only American medical journal published in the German language. Among its contributors, are Drs. Roosa, Heitzmann, Weber, Mundé, and others, who give it promise of a high standard of medical excellence.

— In an article in No. 41 of the *Lyon Médical*, Dr. Augagneur draws attention to the deplorable condition of the girl apprentices, who, drawn chiefly from the healthy regions of the Alps and Savoy, are subjected to a life of hard labor under the most unsanitary conditions. Overcrowded into small abodes under the *padrones* to whom they have been consigned, they live and sleep in unventilated rooms, passing long hours of labor, even extended sometimes on Sundays, and feed upon a most insufficient diet. The consequence is that the hospital of the Croix Rouge exhibits a greater mortality from phthisis than any other hospital in Europe, a third of its mortality being due to this

cause. Against this state of things no legal remedy exists, the laws which supply inspection and control only having power in the large workshops, and not applying to the wretched abodes in which these girls work.

## BOSTON.

—The latest intelligence regarding the Boston Board of Pension Examiners, is that Dr. J. G. Blake has resigned, and that the Board is organized with Drs. Bartlett, Ahearn, and Prince.

## NEW YORK.

—A reception was held at the new Manhattan Hospital, at 10th Avenue and 131st Street, on the evening of December 12th, and the buildings were opened for patients on the 14th. By a recent fair at the University Club Theatre, the sum of \$10,000 was raised by the Ladies' Association for the institution. It is the only general hospital north of the city reception hospital at 99th Street, and has grown out of a free dispensary service which has been maintained in the neighborhood for over twenty years.

—The eighteenth anniversary of the Presbyterian Hospital was held December 13th, when the report showed that during the year past, 1,041 male and 406 female patients were admitted, making, with those remaining from the previous year, 1,535 treated, of whom 102 died. A large addition to the buildings, with an out-patient department, is in contemplation.

—A medical students' missionary conference was held in the hall of the Young Men's Christian Association, December 13th, and among the speakers were Professors C. R. Agnew and W. H. Thomson. The Rev. Dr. Hopper, of Canton, said that there were now eighteen hospitals and twenty-four dispensaries in China, which have been founded by medical missionaries, the oldest of which was established in Canton, in 1835.

—Charles Kaufman, of Franklin Township, New Jersey, sailed for France December 16th, in order to be treated by Pasteur. Dr. O'Gorman, of Newark, having provided him with the necessary funds. He was bitten by a dog supposed to be mad, as long ago as November 21st, so that, at least, thirty-five days will have elapsed before he will be in Paris. A veterinary of Newark, who was bitten by a pug dog which was brought to him for treatment, and was afterward found to have rabies, has also been solicited to go to Pasteur, but refuses. As soon as he received the bite, he heated a poker and thoroughly cauterized the wound. A case of probably spurious hydrophobia in a girl of ten years, is reported from Port Jarvis, N. Y. The symptoms came on ten days after she was bitten by a dog which has not proved to be mad, and, according to the last accounts, the child's condition was improving.

—Dr. H. M. Biggs, who recently started for Paris, did not go in company with Dr. Billings and the Newark children, but independently, as a representa-

tive of the Carnegie Laboratory, and he will visit Koch's Laboratory, in Berlin, before his return. All the expenses of his trip are to be borne by Mr. Carnegie, who has also recently given \$6,000 for the purchase of additional apparatus for the Laboratory which bears his name.

—Quite a number of cases of trichiniasis have occurred among a party who partook of slightly-cooked ham at a supper on Thanksgiving Eve. Several members of one family, who are now under treatment at the Trinity Infirmary, in Varick Street, are likely to die of the disease; but of eight or ten other persons who have been suffering from it, all have recovered but one, who is seriously ill at the New York Hospital. The most severe cases seem to have been among those who ate slices of the ham cut from near the bone; while several individuals who ate from the outside portions escaped entirely.

—Dr. Edson, of the Health Department, recently seized, at the West Washington Market, the carcasses of eighteen hogs which had died of hog-cholera.

—Cases of small-pox and other contagious diseases will now no longer be received on Blackwell's Island, but will be sent to the new hospitals which have been erected on North Brothers' Island.

—Diphtheria has been somewhat on the increase in the city since the first of October. During the week ending December 12th, eighty-seven cases of it, and forty-four deaths, were reported.

—A somewhat virulent outbreak of scarlet fever has occurred at Marion, a suburb of Jersey City, and it is charged that the school which all the children attacked attended has been in an unwholesome sanitary condition. There seems to be no doubt, at all events, that the place was greatly overcrowded.

—Both the Board of Trustees and the Faculty of the College of Physicians and Surgeons have passed appropriate resolutions in regard to the death of Mr. Wm. H. Vanderbilt. Among the numerous charitable bequests of the deceased millionaire, are \$100,000 to St. Luke's Hospital, and \$50,000 each to the Home for Incurables and the New York Christian Home for Intemperate Men. The largest bequest is \$200,000 to the Vanderbilt University at Nashville, Tenn.

## ASPIRATION OF THE AORTA.

The following remarkable case and operation are reported in the *Bristol Medical-Chirurgical Journal* for September, by Mr. J. Dacre, as follows: A laborer, aged forty, was brought to the Infirmary suffering from extreme dyspnoea and cyanosis. He had no enlargement of the superficial veins in the neck or arms, the heart sounds were inaudible, nor could the impulse be felt, the breathing was slow, shallow and gasping, and the conjunctivae were insensitve. Under these circumstances, it was decided to try and relieve the heart by tapping the right auricle. A medium-sized needle was accordingly inserted in the fourth intercostal space on the right side, close to the sternum, and when in the

chest, the point was turned sharply inwards under the sternum, and pushed on for an inch and a half, when it was felt to be in a cavity, but there was no impulse. On removing the needle, black blood flowed freely through the canula, and the heart's action was so far restored as to communicate an impulse to the syringe; when sixteen ounces had been drawn off, there was a very fair pulse at the wrist; in five minutes, thirty ounces had been withdrawn, and the operation was then stopped; no hemorrhage took place through the puncture. The lividity was much diminished, he became conscious, breathed more readily, and was able to speak. A few minutes later he became very restless and his pulse failed; this, however, was relieved by the hypodermic injection of ether, and for the next few hours, he went on fairly well.

Six hours after the operation, his condition having again become very serious, he was tapped a second time, the needle being inserted at the same spot, and in the same manner as before; sixteen ounces of venous blood were removed, and for a few minutes the pulse revived. He then became more restless than ever, complaining of feeling very hot, and in spite of stimulation, he gradually sunk, and died in about forty minutes from the time of the second operation. At the *post mortem*, it was found that the needle had passed immediately above the right auricular appendix, and had pierced the anterior surface of the aorta, about a quarter of an inch above one of the semilunar valves. The author concludes his paper with some remarks on the advisability of cardiacentesis, and observes that the auricle would have been reached in this case if the needle had been passed in directly backward.

#### THE ANNUAL REPORT OF THE COLLEGE OF PHYSICIANS OF PHILADELPHIA.

At the December meeting of the College, the standing committee presented their annual reports.

The *Library Committee* reported that the library now contains 33,686 volumes and 1,393 unbound pamphlets, an increase in the year of 2,592, as compared with 1261 in 1884, and 869 in 1883.

The books are classified as follows:

General Library . . . . .	18,069
Lewis Library . . . . .	8,736
On special deposit:	
Mütter Museum . . . . .	86
S. D. Gross Library . . . . .	5,130
The Hodge collection . . . . .	1,665
Total . . . . .	33,686

The library is in receipt of 181 current periodicals devoted to medicine and the collateral sciences.

The number of books taken out during the year, not including the large number which have been consulted in the rooms, was 1,234. In the General Library, all the books are catalogued with the exception of the dictionaries, journals, reports, and pamphlets. In the Lewis Library, all the books are catalogued to date.

During the year, additional bookcases were erected in the large hall, affording accommodations for about 2,600 books. These cases are now full.

The *Committee on the Directory for Nurses* reported that the number of nurses registered December 1, 1884, was 419. The present number is 475, showing an excess of 56. During the year, the loss by dismissal,

resignation, death and removal, was 18. The number of applicants for registration was 118, of whom only 68 were registered.

The largest number of nurses sent out in any one month, was in January, 1885, 119; the smallest in August, 47. The total number of nurses supplied during the last four years, has been in 1881-82, 342; 1882-83, 733; 1883-84, 913; 1884-85, 1,003.

Seventeen wet-nurses were furnished during the year.

The committee has recently assisted the New York Academy of Medicine in establishing a similar directory for nurses in that city.

### Correspondence.

#### DR. FIFIELD'S ATTACK ON THE MASSACHUSETTS MEDICAL EXAMINER SYSTEM.

BOSTON, Dec. 21, 1885.

MR. EDITOR,—The following letter from the Hon. Clark Bell, of the New York bar, is the spontaneous expression of a gentleman who knows whereof he speaks. I think that those of your readers who have taken an interest in the recent discussion concerning medical examiners will appreciate the disinterested testimony which this letter contains, and therefore I submit it to you for publication.

Very truly yours,

F. W. DRAPER.

NEW YORK, December 19, 1885.

DEAR DOCTOR DRAPER,—I have read Dr. Fifield's paper with astonishment. He seems by it not to know much about medical examiners, nor the work of these men as a body. Conceding that the coroner system was rightfully displaced in Massachusetts, does he seriously desire "that this should pass away and give place to something better?"

The question of how medical examiners should be appointed was always a doubtful one with me. I never dared to recommend in this State appointments by the Governor. It would be next to impossible here to keep it out of the mire of politics, but in Massachusetts it has worked admirably. I sat at table with Governor Long and discussed this with him, at your State Medical Banquet, some years ago. The selections were, from my standpoint, admirable, and the best that could be made. I feel sure that your governors have earnestly endeavored to find and name the best men. When you contrast these selections with the old coroners, as to fitness, efficacy, and practical capacity for the work, the gulf is as wide as that which divided Lazarus from the rich man!

Shall we condemn a system on eight years' trial, that has made such tremendous advance as the Massachusetts system has, and which has engaged the thoughtful attention of publicists in every American State, and excites the attention of our British friends?

Dr. Fifield does not comprehend the spirit or the philosophy of your State Act. The medical examiner should be the arbiter of only the medical questions involved. The Court and District Attorney with you represent the legal side. Under the French system, the *Procureur du Roi* is the judicial mover and prosector, before the Tribunal, and he has enormous power. The medical officer, however, is supreme there within his domain. Both work in union and for a common end. The *expert* is a third factor there, a recognized element, and he is under the control of the legal official, what we call the detective, but what in France is one of the essential elements used in the detection of crime.

If your law is to be amended, it should enlarge, rather than contract the powers of medical examiners. They should be compelled by law to make an autopsy, if the slightest reason existed for even suspicion or doubt as to the cause of death.

It is too absurd for discussion that the District Attorney, mayor or selectmen must be consulted even, much less consent, before an autopsy be made.

The propriety of an autopsy is a medical question, not a legal one, and the medical man cannot be held to too great responsibility in this regard. Tying his hands because it costs thirty dollars, is an economical idea unworthy of Massachusetts.

The system in Massachusetts, though new, is marvelously successful. It challenges the admiration of us all. It is wonderful how few defects experience detected in its practical operation in the State.

Let Dr. Fifield learn not only how many medical examiners there are in Massachusetts, but the work they are doing and have done. Show him and the medical profession, and if needs be the public, the magnificent data I saw in their elaborate and technical reports. There is no such information given in this minute detail in any country in the world.

I have looked upon the action of your State as highly commendable, as an enormous step upward and forward, and I see nothing in the paper of Dr. Fifield which should justify the withdrawal of my confidence in the Massachusetts Medical Examiner, or in the method of his appointment, so far as your State goes.

No one would hesitate at all to second any movement calculated to elevate the standard of medical examiners. I do not object to the closing substitute of Dr. Fifield as to qualifications. Let your medical colleges take higher standards on teaching Forensic medicine than many of them do.

The American colleges have much more to answer for, from their neglect of properly teaching medical jurisprudence than the medical examiners of Massachusetts as a body, as I know them, have for want of ability and capacity for the proper discharge of duty. They are singularly well equipped for their work, and the Massachusetts Medical-Legal Society, by its useful labor and co-operation has supplied a serious defect in Massachusetts medical education (which is not, however, behind other States by any manner of means) by forming and enforcing a general plan of practical discharge of duty, which, whenever it is brought to public attention will challenge the admiration of all competent to judge concerning it.

Please excuse this long and hastily written note, which you can use before your society or otherwise, as you deem best, on this discussion. I am, dear doctor,

Very faithfully yours,

DR. F. W. DRAFER, CLARK BELL.  
36 Worcester Street, Boston, Mass.

# REPORTED MORTALITY FOR THE WEEK ENDING DECEMBER 12, 1885.

Deaths reported 1,733; under five years of age 551; principal infectious diseases (small-pox, measles, diphtheria, and croup, whooping-cough, erysipelas, fevers, and diarrhoeal diseases) 259, consumption 260, lung diseases 188, diphtheria and croup 133, typhoid fever 27, whooping-cough 21, diarrhoeal diseases 22, malarial fever 19, scarlet fever 19, cerebro-spinal meningitis eight, measles three, erysipelas three, typhus fever one. From diarrhoeal diseases, New York 12, New Orleans four, Nashville two, Boston, Charleston, Fall River and New Bedford one each. From malarial fever, New York seven, Baltimore five, New Orleans four, Philadelphia District of Columbia and Charleston one each. From scarlet fever, New York and Springfield four each, Boston three, Philadelphia and Baltimore two each, District of Columbia, New Bedford and Chelsea one each. From cerebro-spinal meningitis, Nashville and Springfield two each, New York, Worcester, Lowell and Frampton one

each. From measles, New York three. From erysipelas, New York three. From typhus fever, New York one.

In 105 cities and towns of Massachusetts, with a population of 1,260,308 (population of the State 1,941,465), the total death-rate for the week was 16.26 against 14.33 and 18.48 for the previous two weeks.

For the week ending November 28th, in the Swiss towns, there were 38 deaths from consumption, lung diseases 19, diarrhoeal diseases 12, diphtheria and croup six, typhoid fever two, small-pox and whooping-cough, each one.

The death-rates were: at Geneva 18.2; Zurich 19.4; Basle 9.1; Berne 26.2.

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE FOR THE WEEK ENDING DECEMBER 12, 1885.

YEMANS, H. W., passed assistant-surgeon. Granted leave of absence for fifteen days, December 7, 1885.

BRATTON, W. D., assistant-surgeon. When relieved to proceed to San Francisco, Cal., December 12, 1885.

NORMAN, SEATON, assistant-surgeon. Appointed an assistant surgeon, December 11, 1885. Assigned to duty at New York, N. Y., December 12, 1885.

#### SOCIETY NOTICES.

The first meeting of the Alumni Association of the Woman's Hospital in the State of New York, will be held at the New York Academy of Medicine, Wednesday, January 20, 1886. The order of exercises will be as follows: Morning Session, 9:30 A. M. to 1 P. M.; 9:30 to 10 A. M., Calling of the roll, Address of the Chairman. 10 to 11 A. M., "The Treatment of Cancer of the Uterus; High Amputation vs. Total Extirpation" by Dr. William H. Baker, of Boston. 11 to 12 A. M., "The Use of the Uterine Dilator in the Treatment of Dysmenorrhea, and as an aid in Intra-uterine Therapeutics," by Dr. W. Gill Wythe, of New York. 12 A. M. to 1 P. M., "Local vs. General Treatment in Gynecology," by Dr. Andrew F. Currier, of New York. Afternoon Session, 2 to 3 P. M.; 2 to 3 P. M., "The Non-Surgical Treatment of Anterior Displacement," by Dr. F. H. Ingalls, of Hartford. 3 to 4 P. M., "A brief Study of the Causes of Retroflexion and Prolapse of the Uterus," by Dr. George T. Harrison, of New York. 4 to 5 P. M., "The Exaggerated Importance of Minor Pelvic Inflammations," by Dr. Henry C. Cox, of New York. Business and Social Meeting at 8 P. M.

NORFOLK DISTRICT MEDICAL SOCIETY. - A meeting for Scientific Improvement will be held at Room 7, Palladio Hall Building, corner of Warren and Dudley Streets, Roxbury, on Tuesday, December 29th, at 7:45 P. M. Communications: 1. "Arsenic Poisoning," Joseph Steinhilber, M.D. 2. "A Case of Multiple Sarcoma of the Skin," C. A. Cleverly, M.D. 3. "A Case of Femoral Aneurism," C. A. Benis, M.D. Particular attention is called to the place and time. A cordial invitation is extended to members of other Districts to be present at the meetings of the Norfolk District, and participate in its discussions.

S. ALLEN POTTER, M.D., Secretary.

#### DEATH

164 In Boston, December 15, 1885, Frederick Howard Lombard, M.D., M. M. S. S., aged thirty-three years.

#### OBITUARY.

The death of Dr. John W. Sawyer, late superintendent of the

In the 28 greater towns of England and Wales, with an estimated population of 8,006,146, for the week ending November 28th the death-rate was 21.3. Deaths reported 3,633; infants under one year of age 901; acute diseases of the respiratory organs (London), 480, measles 120, whooping-cough 90, scarlet fever 42, fever 43, diarrhoea 49, diphtheria 33, small-pox (Liverpool two, London and Birkenhead one each) four.

The death-rates ranged from 14.9 in Leicester to 34.3 in Preston; Birkenhead 17.4; Birmingham 21.6; Bradford 19.5; Brighton 28.2; Leeds 18.5; Liverpool 25.8; London 20.6; Manchester 25.0; Nottingham 25.7; Sheffield 18.8.

In Edinburgh 21.7; Glasgow 26.8; Dublin 25.1.

Boston, was as follows, according to observations furnished by

Butler Hospital for the Insane, at Providence, R.I., will cause wide-spread regret. Dr. Sawyer was a specialist of approved ability and most valuable experience, and he performed his delicate duties in a manner acceptable to all who came within his care. He was for many years a witness in very many of the cases here the Rhode Island courts in which the question of sanity was raised, and his views were always received with the highest regard. He was mild, winning and gentlemanly, yet, when necessity required, of firm disposition. His death was due to blood poisoning.

#### RESOLUTIONS.

At a meeting of the Boston Medico-Psychological Society, held on the evening of December 17th, the following resolutions were unanimously passed:—

*Resolved.* That in the sudden and unexpected death of Dr. John W. Sawyer, superintendent of the Butler Hospital for the Insane, the medical profession has lost a most valuable member; the hospital over which he presided a careful, able and conscientious executive, and the insane an untiring, faithful, and trusted friend.

A man of few words, he seemed thereby to gain added strength for deeds, and though his death occurred at a comparatively early age, he had already accomplished the work of an ordinary life-time.

*Resolved.* That the secretary be instructed to transmit this expression of sympathy of the Society to the family of the deceased, and cause the same to be published in the *Boston Medical and Surgical Journal*.

WALTER CHANNING, M.D.,  
THOMAS W. FISHER, M.D.,  
Committee for the Society.

#### BOOKS AND PAMPHLETS RECEIVED.

Erysipelas of the Larynx and Pharynx. By D. Byron Delavan, M.D., New York. Read before the American Laryngological Association, June 21, 1885. (Reprint from the New York Medical Journal, September 12, 1885.) New York: D. Appleton & Co. 1885.

Sixth Annual Report of the State Board of Health, January and Charity of Massachusetts. Supplement containing the Reports and Papers on Public Health. Boston: State Printers. 1885.

Report on Ophthalmology. Read before the California State Medical Society, April, 1885, by A. M. Wilder, M.D., Late Surgeon and Brev. Lieutenant Colonel, U. S. Army, etc. (Reprint from Transactions of Medical Society of the State of California.)

Practical Suggestions respecting the Varieties of Electric Currents and the Uses of Electricity in Medicine, with Hints Relating to the Selection and Care of Apparatus. By Ambrose L. Ranney, M.D. New York: D. Appleton & Co. 1885.

## Lecture.

## MULTIPLE ABSCESS OF THE BRAIN.—CEREBRAL SYPHILIS.

A CLINICAL LECTURE DELIVERED AT THE HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

BY H. C. WOOD, M.D., LL.D.,

*Professor of Diseases of the Nervous System in the University of Pennsylvania.*

GENTLEMEN, the first portion of the hour will be devoted to the discussion of an exceedingly interesting case, the specimens from which are on the table. The patient was before you on, at least, two occasions during life. I showed him to you last week, in a condition of profound stupor. As you will see shortly, the diagnosis made during life, was, in a measure, incorrect, while, at the same time, it was, in a measure, correct. The case illustrated very well the limits of exactness in the diagnosis of disease of the brain.

Before referring to the specimens, let me refresh your memories by giving a sketch of the history of the patient. The man was admitted to the wards of the hospital on October 15, twenty-one days ago. He was about twenty-one years of age. His mother stated that he had never been sick until last January, at which time he was stabbed in the left side, and was an outpatient at the Pennsylvania Hospital for three weeks. The mother stated that during February, he was sick in bed with erysipelas of the face, but he denied this, and there was some doubt about the statement. At the time of my diagnosis, I did not believe that he had had erysipelas. In May, he was well enough to work, and worked for several weeks. About this time, however, he began to have some kind of fits. These attacks seemed to be worse, according to his statement, during warm weather. He had intervals lasting several weeks, in which he was free from the fits, and in which he was able to attend to his work, that of a brick-maker. The convulsions lasted about five minutes; and he could not tell when they were coming on. There was no aura.

September 30th, he had an attack of partial paralysis of the right side of the body and of the face, associated with convergent squint. According to his statement, there was, at this time, some difficulty with speech.

He had gradually lost the power of walking, so that, when admitted to the hospital, he walked very little. He said that he had suffered with severe pains in the limbs, and also in the head, and that he had frequently vomited. During the two weeks preceding admission to the hospital, he had vomited nearly every day. There was no trouble with the bladder. It was affirmed that during September, he had lain for two weeks in a condition of great stupidity, but could be aroused to answer in monosyllables. There is also a note in the record of the dispensary, which states that on August 10th, a soft swelling, resembling a gumma, was observed, and that this disappeared while the man was taking iodide of potassium, thus confirming the suspicion of the physicians in the dispensary, that the man had syphilitic disease. The nature of this swelling, in the light of recent developments, remains obscure.

When the man came into the hospital, he was in a very stupid condition, answering questions very slowly and imperfectly, and only after he had been aroused by shouting and shaking. He lay with his eyes half closed, paying no attention to what went on around him. The right arm and right leg were partially paralyzed,

and he was scarcely able to move the arm. Sensation was blunted on the same side, but not to any great degree. The man could walk a little, but with a limping, halting gait. The sight was much impaired, the pupils somewhat dilated and sluggish. There was convergent squint. The tongue was protruded to the right, and the right side of the face was paralyzed.

You will remember that in this case, the diagnosis of cerebral syphilis was reached, but of this more anon. I mention it simply to show the reason for the treatment. He was at once put on small doses of calomel. Two days later, he seemed brighter, and answered questions when spoken to, in an ordinary tone of voice. He had, about this time, a slight convulsion, which was confined to jerking of the right arm. According to the best information we could obtain, there was, during this attack, no movement of the face and no loss of consciousness. Examination of the eyes with the ophthalmoscope, showed excessive choked discs on both sides, indicating either meningitis or great brain pressure. Under the continued use of calomel, the man continued to improve until his recovery was expected, but on the evening of October 19th, at 11 P. M., his temperature went up to 101.4°. The morning and evening temperature had previously been normal. Slight twitching and jerking of the left shoulder was now noticed. He seemed a little duller, and did not answer questions so readily. The pupils were contracted and fixed to light. On the 20th, he had another slight convulsion. Again, under the use of mercurials, amelioration was secured, and on the 27th, the man talked perfectly plain, his temperature was normal, the pulse was rather strong, from 96 to 100 per minute, and the respirations normal. The right side of the face moved to a certain degree at this time, and the right arm and leg could be used better than at any time since admission. On October 30th, he was noticed to be getting more drowsy and heavy towards evening, but the change was not sufficient to attract much attention. During the night of October 31st, he became rapidly comatose, and at five o'clock in the morning, he had a convulsion, which is said not to have been severe. You saw him later on the same day, perfectly unconscious, not being aroused by shaking or shouting, and he died a few hours later. During the last hours of life, the temperature rose rapidly, reaching 105°.

I have, perhaps, given you the features of this case too much in detail for you to carry them in your mind. Let me, therefore, briefly sum up the facts in this case. The man, having previously been in perfect health, was stabbed in the left side in January of this year. Some weeks later, he has an attack of erysipelas of the head, keeping him in bed some weeks. He recovers and goes to work. In May, he is suddenly seized, without any warning or any apparent cause, with a convulsion. These convulsive attacks continue to recur through a number of months, occurring at irregular intervals, and apparently epileptiform in character, although there is reason to believe that the right side was especially affected. The man suffers from severe headache and spells of vomiting, grows more and more drowsy, and becomes stupid, and exhibits, to a certain extent, that peculiar commode which is so frequently seen in cerebral syphilis. He is admitted to the hospital, becomes almost comatose and partially hemiplegic, receives mercurial treatment, and under this, the mind clears up, and he appears to be getting well, but suddenly relapses, in the course of one night, into a coma.

tose condition and dies the following day, death being preceded by a marked rise in temperature.

I regret to say that, in making the autopsy of this case, we were compelled to confine our examination to the head. On opening the cranium, it was noted that there was no marked effusion anywhere; that the membranes were intensely congested, and that the dura mater was entirely free from adhesion to the skull, except in one locality, to which I shall refer later. Here it was attached to the skull above and to the brain below. Then we noticed that over the whole vault of the cranium, the arachnoid and pia mater were closely coherent to the surface of the brain. They could not be removed without tearing the brain structure. They were also distinctly thickened. Turning the base of the brain upwards, the sulci and fissures were found to be completely obliterated by exudation. There was also considerable exudation at the base of the brain, and involving the optic tracts.

Finding this condition, I said to myself, the diagnosis was correct, for this is what we expect to find in syphilis of the brain. My self-congratulation, however, received quite a shock, when, on plunging a knife into the left hemisphere, a stream of pus gushed forth. Two or three ounces of pus escaped from the centre of the brain. The incision into the brain was then enlarged, and it was found that the lateral ventricle of the left side had been filled and its walls destroyed by this collection of matter. Further examination showed that the pus had been confined in a sac located in the parietal lobe, and that the destruction of brain tissue in the neighborhood of the ventricle was due to the rupture of this sac into the ventricle. The sac of the abscess had been almost completely dissected out by the discharge of its contents, so that it lay in this cavity, attached only at its lower portion. I now show you the sac. At its lower portion, is a little tumor which I have not yet opened, about the size of a large hickory nut. I now incise it, and, as you see, pus escapes.

As can be readily seen, the abscess within the brain did not come within one inch of the point where the membranes were adherent at the vault of the skull, and it seemed curious that there should have been a localized meningitis in that situation. However, on cutting into this point, a third abscess was found immediately below the thickened membranes. We had then a case of chronic abscess of the brain, with three abscesses, all situated in the left hemisphere.

I wish to say a few words in reference to the bearing of this case on diagnosis. We had positive evidence of the existence either of meningitis or of some gross lesion of the brain, which was accompanied with increased pressure in the general symptoms of headache, hemiplegia, localized convulsions, and especially, in the double-choked discs. This so-called descending neuritis, or choked disc, comes from one of two brain conditions. It is either the result of meningitis, especially of the base, or it is dependent on some disease which increases enormously the brain pressure. It has been found in abscess of the brain, in two classes of cases; one in which with the abscess there is meningitis, in the other, in which there is no meningitis; in other words, either inflammation of the meninges, or increase of the general brain pressure is enough to produce choked disc. I have seen unmistakable choked disc in one or two cases, in which I believe the disease was local, and in which, after watching the cases for many months, I was unable to find any brain symptoms.

Where, however, along with choked disc, there are marked symptoms of brain disease, there is positive proof either of meningitis or some disease of the brain, associated with increased brain pressure.

When I made the diagnosis before you, I told you that I was certain, up to this point, that there was some gross brain lesion, which was focal in its nature. The next question that arose was as to the nature of this lesion. In order to determine that, we had to judge from the history of the case and the general course of the symptoms. Whenever you go beyond the point of determining that there is a focal lesion, and undertake to say what the nature of that lesion is, you are getting into a region of doubt, and every now and then, must come to an erroneous conclusion.

We seemed to have, in this instance, a history of gumma of the scalp. We had the symptoms coming on in a man known to be lewd, and who had been exposed to the contagion of syphilis. We could, however, obtain no history of syphilis from the man himself. In the immense majority of cases, where there is a focal lesion of the brain, developing slowly in a young person, it is due to cerebral syphilis. From the evidence at our command, we came to the conclusion that this was probably a case of that character. When the man improved under antisyphilitic treatment, we were confirmed in our error.

The correct diagnosis in such a case as this ought to be reached during life, if the history is perfectly clear. If we could have relied on the statements of the man and his friends, it should have been made. The father insisted that the head trouble was the result of the stab on the side, but it seemed to me incredible that the lesion, which I considered to be due to syphilis, could be dependent on this injury, and the intercurrent erysipelas attack I only knew of after the death. If there had been a history of traumatism to the head, the diagnosis of abscess would undoubtedly have been made. Where there are symptoms of focal lesion following cephalic traumatism, either immediately or at a long interval, the probability of abscess is to be borne in mind. The abscess may first appear a long time after the injury supposed to cause it. There are cases on record, seemingly well authenticated, in which the symptoms have not appeared until fifteen or twenty years after the injury. In this case, however, no history of traumatism of the head could be elicited, and the diagnosis of cerebral syphilis was made.

Cerebral syphilis was perfectly competent to account for most, if not all, the symptoms in this case. The symptoms in a focal lesion of the brain are not the result of the nature of the disease, but are dependent on the seat of the lesion. If there had been a rapidly developing syphilitic tumor at the position of the abscess, there would have been similar symptoms. But on thinking over the case since the man's death, it has occurred to me that in the hundreds of cases of cerebral syphilis which have passed under my care, not once (so far as my memory or notes go), have vomiting spells, similar to those which this poor man suffered, been present.

Another point of great interest, which presents itself, is in reference to the cause of the abscess. Abscess of the brain is almost invariably the result of septic poisoning, or of traumatism. The books speak of embolism as a cause of cerebral abscess. I believe that embolism never produces abscess of the brain, unless the embolus be loaded with septic poison. If

the embolus simply blocks an artery, the result is simple softening. If, however, the infarct is poisoned, it excites inflammation, and becomes the centre of an abscess. Possibly there is such a thing as idiopathic abscess of the brain, but such a condition must be exceedingly rare; and after all, gentlemen, the more we know of medicine, the more we see that idiopathic local diseases are always rare. A boil comes on a man's arm, and we call it idiopathic, because we do not see the reason for it. We say that it is self generated. It is probably not so at all. It has come on the arm because there has been something in the nervous condition of the part which has led to this local manifestation. Abscess of the brain is probably always the result of traumatism, or of some blood condition. Septic abscesses are rare. They are usually acute, but not always. They are not uncommonly multiple. Abscesses, the result of traumatism, are usually single.

With the history of the man's attack, as we had it from himself and from his parents, and with the existence of three abscesses within the brain, I think that we are thoroughly warranted in considering the case one of septic brain abscess. When a septic abscess is acute, it softens the brain rapidly, producing an acute encephalitis, and the brain becomes more or less infiltrated with pus. Where, however, the abscess is sacculated, the symptoms are always latent, and the disease runs a long course. The man in this case undoubtedly died from the rupture of the abscess into the left ventricle.

It will also be interesting to consider for a moment why the man improved under antisyphilitic treatment. Bear in mind that in this case, as in many other cases of brain abscess, there was also diffused meningitis. When the man was admitted, his stupor was the result of cerebral congestion, and there probably was some oedematous exudation due to the congestion. Both the congestion and oedema were as much dependent on the meningitis as on the abscess. We gave mercury, and under the influence of this remedy, there was lessening of the inflammatory process, and a partial clearing up of the mental condition. The last overwhelming coma was the result of the tearing out of the whole interior portion of the left hemisphere, by the pus of the bursting abscess.

Of course in a case like this, there is no treatment. If the abscess is located in a portion of the brain where its position can be localized with considerable exactness, it may possibly be justifiable to trephine the skull, and try to evacuate the pus. In a large majority of cases, however, of local brain disease, it is impossible to say, with absolute certainty, where the lesion is located. It could not have been diagnosed in this case. We knew that the man had a lesion somewhere, either in the central portion of the brain, or in the neighborhood of the ascending frontal convolution. In many of these cases, as in the present one, the symptoms of meningitis largely overshadow and mask the symptoms due to the local disease.

#### CEREBRAL SYPHILIS.

I shall now bring a patient before you, and shall make the same diagnosis which proved faulty in the preceding instance, and shall give you my reasons for so doing.

The following is the story which we have obtained, but the man's mental condition is such that we cannot implicitly rely upon his statements. It is said that up

to Friday, October 23d (two weeks ago), he was perfectly well. At any rate, he was able to work in a stone-quarry on this day. He states that while working, he felt bewildered, things swam before him, and he sank unconscious on a heap of stones. An important point is, that the man was picked up unconscious, but during the ride to the hospital in the ambulance, regained consciousness. At this time there was no hemiplegia. There was not the paralysis of the left side which is now present. The following day it was observed that the left side was partially paralyzed, and this was gradually increased. Examination of this man's eyes revealed no choked discs, but remember that while the presence of choked discs is of value, its absence is of no importance from a diagnostic standpoint. In one case, in which I had diagnosed brain tumor, the eyes were examined by a distinguished ophthalmologist, and nothing abnormal was found. The following day the man suddenly died, and the autopsy showed a tumor as large as a hen's egg. Therefore, I say that while the presence of choked discs is of great importance in diagnosis, its absence is of little significance.

Although this man has no choked disc, yet he undoubtedly has a focal lesion. He undoubtedly has hemiplegia, of brain origin. He has heaviness of mind, sluggish pupils, somewhat dilated. Hemiplegia produced by other than focal lesion of the brain is exceedingly rare. Having also other symptoms of brain implication, there can be no question as to the cerebral origin of the paralysis.

We next consider the probable nature of this lesion. The first thing that would suggest itself would naturally be that the man had a stroke of apoplexy, and that he fell with a clot in his brain, and that the hemiplegia was due to cerebral hemorrhage. Mark, however, that the hemiplegia did not appear until several hours after the attack. If, during the period of unconsciousness and brain congestion, blood had been poured out, the hemiplegia would have been developed at once. In this instance, the hemiplegia gradually increased through several days. In hemiplegia resulting from the pouring out of blood into the brain, there is rarely this increase. At its first outpouring, the blood tears and shocks the brain, and the symptoms subside as the brain becomes accustomed to the presence of the clot, unless the lesion is so severe as to destroy the conducting power at the position of the clot. For these reasons, I cannot believe that this focal lesion is of the nature of a clot.

The lesion is probably not of the nature of an embolism, for if a thrombus of sufficient size to produce so much hemiplegia had formed, the symptoms would have developed as rapidly as in hemorrhagic apoplexy.

If this be not a case of apoplexy, or a case of thrombus, what is it? I learn, in the first place, that the man has a syphilitic history. He has admitted as much. He has a distinct sear upon the head of the penis. He has distinctly atheromatous arteries. If you find a man under thirty years of age with atheromatous arteries, the chances are that the arterial degeneration is due to chronic syphilis. If severe inherited gout can be excluded, the chances amount almost to a practical certainty. Examination of the eyes shows that the patient has lazy cornea, and that there is sub-acute retinitis, which is often associated with syphilis. There is no pain on pressure of the sternum, but I find enlarged glands in various parts of the body.

These facts are sufficient to prove that the man has had syphilis. As he has had syphilis, and we can find no other cause to account for the focal lesion of the brain, we come to the conclusion that the focal lesion is of the nature of a syphilitic infiltration, situated high up in the meninges of the brain, somewhere in the neighborhood of the ascending frontal convolution, or possibly situated, as I have seen it, in one or two cases, in the *velum interpositum*, affecting the parts within the ventricle.

It may be asked why it is that this attack was not preceded by headache. This question is hard to answer, but it is a clinical fact that not rarely, syphilitic disease of the brain makes its first appearance with the quickness and ferocity of a tiger leaping on its prey. The acute attack of congestion and the acute attack of meningitis may be the results of a gradual gummatous inflammation, limited in extent, which has been forming, but producing no symptoms, until for some reason, it suddenly lights up an acute congestion or inflammation.

We know that if the lesion is syphilitic, it is situated in the position indicated, on account of the distinct hemiplegia, with absence of marked eye symptoms. There is, however, some weakness of the eye-muscles, so that probably, in addition, there is some basal exudation. Basal exudation in itself would hardly produce so much hemiplegia. The fact that there seems to be two lesions, would confirm the diagnosis of syphilitic origin, for syphilitic lesions are prone to be multiple.

This man was first put on calomel, in half-grain doses, every hour. This was continued twenty-four hours, when, on account of its action on the bowels, the dose was reduced to one-fourth of a grain. Since then, it has been substituted by iodide of potassium, of which he is now taking one hundred and twenty grains per day. Under this treatment, he is improving, and I think will go on to recovery.

### CASES OF ABDOMINAL DISEASE WITH OBSCURE DIAGNOSIS.<sup>1</sup>

BY FRANCIS MINOT, M.D.,

*Harvey Professor Theory and Practice of Medicine, Harvard University.*

THE difficulty which attends the diagnosis of some diseases of the abdomen, depends, to a considerable extent, upon the absence of definite and characteristic signs relating to them, as well as upon the large number of symptoms which are common to almost all the affections of that cavity. In this respect, they differ remarkably from the diseases of the brain, of the cord, and of the organs within the thorax, which, although inaccessible to the sight and the touch, can, in a large number of cases, be determined with absolute certainty. Exceptions are found in the diseases of the kidneys, whose nature is often ascertained with precision by a comparison of the rational symptoms with the signs furnished by the urine, and in some of those of the liver, when that organ is greatly enlarged, as in cancer, etc., or when the accompanying symptoms are sufficiently definite, as in cirrhosis; but in many instances, it is only by carefully weighing such evidence

as we may be able to obtain, that we can arrive at a conclusion, and that, perhaps, only a conjectural one, as to the diagnosis. Palpation is often of little avail, on account of the presence of gas in the intestines, or of ascitic fluid, and even when the flaccidity of the parietes affords a thorough exploration by that method, there is often a difference of opinion among observers, as to the nature of any tumor which may be plainly felt, or of the organ in which it is situated, and even, sometimes, as in one of the cases to be reported, whether any tumor is to be felt at all. Moreover, the absence of any tumor by no means excludes the possibility of grave organic disease. Even ulcer and cancer of the stomach, two diseases whose symptoms, in typical cases, are so characteristic that their diagnosis is easy, may present absolutely no signs by which they can be distinguished during life, and their presence may only be revealed to us at the post-mortem examination.

The observations which I offer in illustration of these remarks, comprise two cases of gastric ulcer, with perforation; one of cancer of the peritoneum, stomach, and several of the other abdominal organs; and one of cancer of the intestine, ovaries, and uterus. The first case is of historical interest, since it occurred more than two hundred years ago, when the existence of the disease now so familiar to us as gastric ulcer, was unknown; and it is a remarkable instance of the intelligence and sagacity of a man eminent in philosophy and literature, as well as in medicine, who was able, after so great a lapse of time, to diagnosticate absolutely the cause of death of a person supposed to have been the victim of poison administered with criminal intent.<sup>2</sup>

**CASE I. Perforating Ulcer of the Stomach.** The patient was a lady of high rank, Henriette d'Angleterre, sister of Charles II, of England, and wife of the Duke of Orleans, brother of Louis XIV, at whose court she resided. She had complained for some time, of pain in the side and stomach, but was otherwise in good health. On the evening of the 29th of June, 1670, soon after dinner, she drank a cup of chicory water, which she was accustomed to take for the relief of her supposed dyspeptic symptoms. Immediately after swallowing the beverage, she was seized with severe pain in the abdomen, and vomiting. The pain soon became agonizing, collapse followed, and she died at half past two o'clock on the following morning, nine hours after the beginning of the seizure. Our acquaintance with the symptoms and pathology of gastric ulcer, for which we are indebted to Cruveilhier, enable us to see at once, in this history, a probable case of that disease, with perforation, not very rare in young women, followed by fatal general peritonitis; but two hundred years ago, in the absence of any such knowledge, the sudden access of severe and alarming symptoms, speedily followed by death, in a person of high political position, readily suggested murder by poison, an inference rendered more plausible in this case, in consequence of the enmity of a certain Chevalier de Lorraine, who had been sent by the King to reside at Rome, on an ostensible mission, at the instance of Henriette, in order to put an end to the unfavorable influence which she thought he exercised over her husband. Although the physicians in attendance reported that the autopsy revealed no evidence of poison (their diagnosis was cholera morbus, caused by an excessive flow of bile),

<sup>1</sup> Read before the Boston Society for Medical Improvement, December 14th, 1885.

<sup>2</sup> For an interesting account of this case, see an article entitled "Henriette d'Angleterre, Belle-sœur de Louis XIV, est-elle morte empoisonnée," by E. Littré, in *La Philosophie Positive*, September and October, 1867.

and although no one was implicated in the affair, no arrests even having been made, it was currently believed that the chicory water which the princess drank had been poisoned by the Marquis d'Elfiat, a friend of the Chevalier de Lorraine, the drug having been sent from Rome for this purpose by the latter. Even to this day, it is believed that Henriette d'Angletorre perished by a violent death.

The late eminent Dr. Littré, while engaged in making researches in the Bibliothèque Royale, in Paris, about twenty years ago, came across a document written by one of the surgeons of Charles II, containing an account of the autopsy of Henriette, at which he had been present. This report, probably a copy of the official one sent to the King, shows conclusively that Henriette d'Angletorre must have died of peritonitis, following the perforation of a gastric ulcer, as the following extracts show: The peritoneal cavity "was full of a thin, sanious, putrid, yellowish substance, containing oil" (a dose of castor oil had been given to the princess, after the seizure); the omentum and intestines were "mortified and gangrened, and much discolored," expressions which, in terms of modern pathology, indicate simply the presence of turbid serum with recent soft exudation, the result of acute peritonitis. "The stomach," he says, "which I examined very carefully, was externally healthy. The interior was corrugated, and stained from end to end with bile, which was easily removed with the finger, leaving no abrasion in any part, *only a little hole in the anterior and middle part, which was only noticed by myself, and which was accidentally made by the operator*; on careful inspection, I found no excoriation, corrosion, blackness, induration, nor discoloration." That his inference of an accidental cause of the perforation was erroneous is evident from the fact that, along with some of the contents of the stomach, there was found in the peritoneal cavity, a quantity of oil, which the princess had swallowed before her death. Moreover, his description of the lesion, a simple *hole*, without any such appearance such as would be likely to result from the action of poison (which he had in his mind at the time), corresponds to that of the simple perforating ulcer, most frequently found in young women; and the princess was twenty-six years old.

I presume more than one of us must have met with a case in which the sudden death of a young woman in apparent health was found, on post-mortem examination, to have resulted from the perforation of a minute ulcer, which had given rise to no pathognomonic symptoms, perhaps, to no symptoms at all, during life. No autopsy is now needed to diagnosticate the disease after the fatal event, but how rarely can it be detected during life.

**CASE II. Chronic Gastric Ulcer, with Unusual Symptoms.** The following case was referred to me for an opinion by Dr. James Dinnlap, of Northampton, to whom I am also indebted for some particulars concerning the symptoms, and for an account of the autopsy.

March 22d, 1884. The patient, a gentleman, forty-three years old, married, living in Northampton, by occupation a merchant, was of nervous temperament, active, energetic, and inclined to work beyond his strength. His father, healthy, died at seventy-three. His mother died at fifty-three, of gastric ulcer, so supposed. No constitutional disease in the family of either, so far as known.

Sixteen years ago, he had an attack of "chills and

fever," lasting several weeks. During the last twelve years, he had suffered, from time to time, with obscure dyspeptic symptoms, the most important of which was pain, referred by him to the stomach, situated chiefly in the right hypochondrium, sometimes extending over the abdomen, generally, but never felt in the left hypochondrium. During the last two years, it had become more severe, requiring from half a grain to a grain and a half of morphia, hypodermically, almost daily, for several months. It was paroxysmal in character, lasting several hours at a time, recurring often, and was much relieved by firm pressure on the ribs of the right side, so that he would lean against the corner of a table or other hard object to get ease. No increase of pain ever followed his meals. Flatulence was a frequent symptom. The bowels were extremely constipated, and very large doses of purgative medicine were required, which would operate at the end of thirty-six or forty-eight hours, without ever aggravating the pain. There was frequent vomiting, at times copious, and lasting for a day or two, after which he would be free from it for a week or more. The matters vomited were mostly liquid, with a little undigested food, and brownish flocculent particles, sometimes dark, as if bismuth had been taken. On extremely rare occasions, a speck of blood was seen. The appetite, mostly poor, was capricious. Occasionally, he would eat a good meal. The diet which best agreed with him was roast meat, beefsteak, raw and cooked oysters, fresh fish, and white bread and butter. Most vegetables, especially tomatoes, disagreed with him. He either sat up in bed at night, or lay in a semi-recumbent attitude, as the horizontal position increased the pain. Of late, emaciation had increased considerably. There had been no jaundice.

The patient was spare, but not greatly emaciated, and the muscles were not wasted. Height, five feet, seven inches; usual weight, one hundred and twenty pounds; now, about one hundred and twelve pounds. Complexion rather pale, but not otherwise remarkable; no jaundice; no cachectic look; tongue clean; urine natural in quantity and frequency, and stated to be normal chemically; no oedema anywhere. Bowels constipated; sleep good, except during pain.

He said he had been told that he had a tumor in the abdomen, and that there was a question of the expediency of making an exploratory incision with a view to remove it, provided the operation should appear to be practicable. As it was in reference to this point that he desired my opinion, I examined the abdomen with care, and especially, the region of the right hypochondrium, to which he referred his pain. The belly was somewhat retracted, soft, and easily explored, and everywhere free from special tenderness, including the region below the xiphoid cartilage, but I was unable to feel any tumor. The next day, I had an opportunity of examining the patient, in company with the two physicians who believed they had detected a tumor, which they thought to be probably a biliary calculus, occupying the gall bladder or the cystic duct, but I was obliged to confess that I could feel nothing of the kind.

The interest in the case lay chiefly in the obscurity of the diagnosis. It seemed tolerably certain that the disease was confined to the stomach, since during its long course there had been no evidence of derangement of any other organ. Cancer and chronic ulcer at once suggested themselves. In favor of the former was the excessive pain, the emaciation and the vomiting. On the other hand there was apparently no ob-

struction of either orifice: I could feel no tumor, and it was hardly possible that the patient could have lived for twelve years with a malignant disease of the stomach, and without material change in the symptoms during that time. The usual symptoms of gastric ulcer, pain following the ingestion of food, and relieved by vomiting; hæmatemesis, and tenderness in the epigastrium, were wanting. The pain bore no relation to taking food, was chiefly felt in the right hypochondrium, and was relieved by firm pressure on the ribs of the right side. There was no tenderness in any part of the abdomen, even below the xiphoid cartilage. There was frequent vomiting, but never of blood, except that a "speck" was seen on extremely rare occasions, such as might occur with vomiting from any cause. Although the appetite was generally poor, yet a good meal was occasionally taken, and the diet which suited the patient best, "roast meat, beefsteak, raw and cooked oysters, fresh fish, and white bread and butter," seemed incompatible with chronic gastric ulcer, or any other inflammatory condition. On the whole, I was inclined to the opinion that the disease was a neurosis of the stomach, or gastralgia.

Towards the end of January, 1885, I received a letter from Dr. Dunlap, stating that the patient, who during the last four months of his life had been under treatment by a clairvoyant, had been suddenly attacked with intense pain in the bowels, followed by collapse and symptoms of perforation, of which he died in a few hours, October 30. Dr. Dunlap also enclosed an account of the autopsy.

The contents of the stomach were found floating in the peritoneal cavity. An opening in the stomach large enough to admit the tips of two fingers was found in the smaller curvature, two inches from the cardiac orifice. It had smooth, rounded edges. The coats of the stomach immediately surrounding it, were half an inch thick, gradually diminishing to the normal thickness about three inches from the opening, in all directions. Even the extremity of the œsophagus, on the side next the ulcer, was thickened. Nature had made no provision for guarding against the results of perforation: there were no adhesions to the surrounding parts. The stomach was much enlarged, pale and bloodless, even around the perforation. There were no signs of inflammation or ulceration of the mucous surface of the rest of the organ.

A stricture, less than an inch in extent, and beginning at an inch and a half from the pylorus, was found in the duodenum. The gut at the point of stricture would not admit the tip of the little finger; a sizable wood pencil or pen holder would pass readily. The strictured part did not appear diseased; there was no ulceration, no hardness, no cicatrix. Externally, the gut seemed of normal size, or nearly so, and the coats were equally thickened throughout the circumference, but of soft, normal feel.

The other organs were free from disease, though pale, and very slightly friable, probably from inanition. Liver, a little below the normal size. Gall-bladder, nearly empty, containing neither gall stones nor inspissated bile. The cystic, hepatic and common ducts were all very carefully examined, and found to be pervious throughout their extent. The mucous membrane of the intestine was smeared with bile around and below the outlet of the common duct.

The situation of the ulcer in the smaller curvature of the stomach, and near the cardiac extremity, where

it was protected from external pressure, accounts for the absence of tenderness in the epigastrium, as well as for the relief afforded by sitting up in bed. It may also, perhaps, explain why there was no pain following the taking of food, for nowhere else could the mucous membrane be less exposed to contact with the ingesta. The severe pain in the right hypochondrium, sometimes extending over the abdomen generally, except in the left hypochondrium, was probably due to reflex irritation. Several physicians were present at the autopsy, all of whom agreed that there was no appearance of cancer, either in the stomach or in the duodenum.

It is not necessary to review the details of this complicated case in order to show the difficulties which lay in the way of a correct diagnosis. I will only allude to the remarkable fact that two<sup>3</sup> physicians should, under favorable conditions for physical exploration, have been so confident of the presence of a tumor, presumably the gall-bladder containing a calculus, that they advised cutting down upon it; while a third was unable to detect anything of the kind, and the autopsy showed that the gall-bladder was healthy and empty, all the ducts pervious, and no trace of a stone to be found. As to the stricture of the duodenum, we may presume, in the absence of any appearance of structural disease, that it was the result of spasmodic muscular contraction, during the last moments of life.

CASE III. *Cancer of Stomach and Peritoneum.* This case was seen at Framingham, June 17, 1885, with Drs. E. D. Bigelow and G. C. Pierce. The patient was a gentleman, fifty-six years old, married, of temperate habits. There were no special diseases in his family, so far as known. Several years ago he suffered from asthma, but had been free from it of late, and in other respects his health had been good previously to his present illness. In August, 1884, while complaining of dyspeptic symptoms, he vomited a small clot of blood, and from that time he had suffered from flatulence and pain in the region of the stomach, his condition becoming progressively worse. By October the pain had become severe, and he began to lose flesh. In addition to the epigastric pain, there was a good deal of intercostal neuralgia and sciatica, on both sides, during the winter. The emaciation and loss of strength had progressed rapidly during a few weeks before my visit. He had been out-of-doors for the last time within a week, had kept his room for the last few days, and at the time of my visit could only walk with assistance from his chair to his bed, into which he had to be lifted for examination. There had been occasional, but not frequent vomiting, apparently not caused by taking food. Once within a few weeks he had vomited a very little blood, the only time since August. The epigastric pain was nearly constant, unless relieved by morphia, and taking solid food was followed by pain. There was never any dropsy. The urine was normal, bowels in fair condition. Pulse, 96; no cardiac murmur. Tongue dry and smooth, without coat. No jaundice. No nervous symptoms. Aspect cachectic; much emaciation and prostration. Abdomen soft, free from tenderness; no tumor to be felt.

He died July 5th. Dr. Bigelow kindly sent me the following notes of the autopsy, together with the specimen:—

<sup>3</sup> Since the reading of this paper, one of the two physicians has stated that he did not detect the tumor, though he recommended the exploratory incision of the abdomen.

"Body much emaciated. Numerous small ecchymoses over abdomen and lower extremities, skin dry, dull grayish-yellow color. Abdomen distended with six or eight quarts of bloody serum. Peritoneum, visceral, and parietal, was studded over with small, firm, whitish nodules. Omentum and mesentery greatly retracted; the intestines, stomach and pancreas were united in a firm mass by adhesions. The stomach appeared like a firm tube, dilated to the capacity of two ounces at the cardiac extremity, both orifices free from disease. Its inner aspect showed an extensive villous growth on a hard base, this being most marked in the middle third of the organ. Liver contained numerous nodules of secondary cancer. Spleen, kidneys, and lungs normal."

The diagnosis of cancerous disease within the abdomen was obvious from the pain in that region and the progressive and rapid failure of strength and flesh. It was also supposed that the stomach was implicated from the occasional vomiting, and the occurrence of hematemesis, twice, although in very small amount; but as there was no tumor in the epigastrium, and as the vomiting did not appear to be caused by the presence of food, it was concluded that the orifices were free from disease, as the autopsy proved. There was no evidence of peritonitis or hepatic disease, the abdomen being soft, free from tenderness, and containing no tumor, and there was no jaundice.

CASE IV. *Cancer of Intestine, Uterus, and Ovaries.* June 23, 1885. I saw at Lawrence, with Dr. C. W. Chamberlain, a widow, fifty eight years old, who had never borne children. Previously healthy, her present sickness began early last winter with pain in the right hypochondrium, vomiting after eating, constipation and flatulence. These symptoms increased moderately until February, after which they became more severe. The vomiting occurred only at intervals of several days, was usually violent, but could be somewhat controlled by careful diet. The pain was generally caused by food, especially sweet things, and never by hot food, and it was always relieved by vomiting. The constipation was not urgent, and yielded to laxatives. There was no hemorrhage from the stomach or bowels. She never had any symptoms referable to the uterus or ovaries. There was progressive emaciation and failure of strength. She was able to drive out almost daily until June 16th, when she was taken with vomiting, and went to bed, which she never left. She continued to fail, became delirious and lethargic, and died July 18th. Nothing special was elicited by examination of abdomen.

At the autopsy the stomach was found somewhat dilated, the walls extremely thin, the muscular tissue apparently gone, the mucous membrane in places quite reddened; but there was no structural disease. There was a thickening of the bowel three feet below the pylorus, with stricture admitting a blow-pipe a quarter of an inch in diameter, forming a small tumor three-quarters of an inch in length, and less than an inch in diameter, too small to be felt by external palpation. Both ovaries were enlarged to the size of small mandarin oranges, containing cancerous deposits, and cysts out of which a molasses-like fluid came by puncture. There were also cancerous masses in the uterus, the organ not being enlarged, but in a state of senile atrophy.

In this case, also, the diagnosis of malignant disease in the abdomen was inferred on account of the progressive failure of flesh and strength, although no in-

formation was afforded by physical examination, and the rational symptoms furnished no definite indications of local disease. The stricture of the intestine, probably malignant, gave rise to thickening of the walls of the bowel, but the tumor was too small to be detected by palpation. Even the enlarged ovaries were not felt, although it is possible that a vaginal or rectal examination might have revealed the existence of disease in the pelvis, had there been anything in the symptoms to direct attention towards it.

## SOME POINTS IN THE TREATMENT OF SYPHILIS.<sup>1</sup>

BY G. H. TILDEN, M.D.,

Physician to the Boston City Hospital, Department of Diseases of the Skin.

It is nearly twenty years since Sigmund (Wiener Med. Wochenschrift. Nos. 43, 44, 46, 53, 1867) demonstrated the fact that cauterization of the point of inoculation of syphilis, if done within three days from the time of inoculation, was competent in many cases to prevent the development of the malady. A step further in this direction is the prophylactic destruction or excision of the initial lesion itself, and although sporadic attempts of this kind had been previously made, it was not until ten years afterward that marked attention was drawn to the subject, by Auspitz's publication of thirty-three cases<sup>2</sup> in which the initial lesion of syphilis had been excised, in the hope of thereby preventing any further manifestation of the disease. The interest in the subject awakened by this communication of Auspitz has not since been suffered to expire, the question having been under discussion at the last International Medical Congress, and apart from its theoretical interest, it is possessed of practical importance sufficient to render it worthy of careful consideration.

Many of the younger German writers, convinced that the primary lesion of syphilis is entirely local in its nature and merely the nidus, so to speak, from which further infection of the system takes place, insist upon the possibility of arresting the progress of such infection, by early and thorough excision of the initial lesion before the development of inguinal buboes, and as evidence in favor of this view, they give the details of cases in which such excision has been performed with the desired result. Not a few are also of the opinion that in those cases where the removal of the primary lesion fails of preventing the progress of the disease, and such cases are in the very great majority, its further manifestations are of milder and more evanescent character than usual.

Several of the older men among the Germans and all of the French syphilographers, on the other hand, with the single exception of Jullien, believing as they do that the initial lesion is to be regarded as the first symptom of syphilis and that by the time of its development the whole organism is already affected by the disease, deny that its excision is possessed of any prophylactic virtue whatever and produce as evidence many instances in which the earliest possible removal of the initial lesion, under apparently the most favorable conditions, has nevertheless, been followed in due time, by the development of syphilis. They assert that

<sup>1</sup> Read before the Boston Society for Medical Improvement, Dec. 11, 1885.

<sup>2</sup> Vierteljahresschrift für Derm. und Syph., p. 167, 1877.

the apparent success in this direction is explained by the facts, that error in diagnosis gives rise to the excision of lesions not syphilitic in nature, and that incompleteness of subsequent observation affords opportunity for the further manifestations of the disease to escape detection.

Such is the statement of the case. The evidence as to facts is conflicting, the theoretical discussion of the problem, involving as it does, speculation with regard to the nature of the syphilitic virus and the manner of its diffusion through the system, is without definite results and the question is to be regarded as yet unsettled. The only practical outcome of the discussion, thus far, has been to show that excision of the initial lesion is not followed by any bad consequences, when thoroughly done, and with strict attention to antiseptic details. The wound usually heals by first intention and the operation is advisable in suitable cases, substituting as it does, a slight incision which unites in a few days for a pathological lesion, which sometimes lasting for weeks, is a source of annoyance to the patient and of danger to others.

The so-called second period of incubation, of from six to twelve weeks, between the appearance of the primary lesion and the first development of general symptoms, should not as is usually the case, be a period of inaction, but the opportunity should be utilized which it affords, of rendering the patient by suitable hygienic and tonic measures, better able to resist the coming disease. The care of the mouth should receive special attention. The teeth should be put in as good order as possible, by the removal of tartar, the extraction of stumps, and the smoothing down of sharp corners, and the mouth kept in good condition by frequent brushing of the teeth and the use of an astringent and antiseptic wash, since a clean mouth and a sound mucous membrane are the best safeguards against the development of salivation and the formation of mucous patches.

As to whether general specific treatment should be employed during the second period of incubation, there is difference of opinion.

Among others, Professor Neisser<sup>3</sup> of Breslau, discoverer of the "gonococcus," a firm believer in the bacterial nature of the virus of syphilis and in the local character of its initial lesion, is an ardent advocate of the early employment of general specific treatment, on the ground that the sooner the microorganisms in question are subjected to the bactericidal influence of mercury, the better for the patient. The usual custom and I think the proper one, is to wait until the appearance of general symptoms before the employment of general specific treatment. The reasons given by Kaposi for this waiting are, *first*, that the diagnosis is never established beyond a doubt, before the development of the so-called secondary symptoms; *second*, that general specific treatment, although it delays does not prevent their development, and *third*, that when these symptoms develop under such conditions they are apt to be of a deeper seated and graver nature than is otherwise the case.

There may exist, however, exceptional conditions which render it advisable to depart from the usual custom, and this is the case when the initial lesion is in such a position and of such a character as to threaten the impairment of function or serious disfigurement. It was shown in Sigmund's clinic that the

initial lesion, and in fact, any specific lesion will yield more quickly to a combination of local and general treatment than to either of them alone, and therefore, in cases where it is necessary to arrest as much as possible its development, general as well as local treatment may be employed.

Experience has taught, and experiment<sup>4</sup> demonstrated the fact that irritation of the skin and mucous membrane in persons affected with syphilis, more especially in the active stages of the disease, is competent to favor the development and promote the growth of specific lesions. Want of cleanliness is one source of irritation, and the lack of care which will cause balanitis in a healthy person, may in one suffering from active syphilis give rise to the development of mucous patches. The necessity, therefore, of strict and continuous attention to the cleanliness of the various accessible cavities and outlets of the body and to the integrity of cutaneous surfaces which are in contact with one another, should always be impressed upon the patient.

The importance of hygiene and tonic remedies in the treatment of syphilis can hardly be overstated. With their aid alone, a patient possessed of a good constitution may recover from the disease; without them, the most energetic specific treatment may be of no avail, a fact occasionally demonstrated by some wretched syphilitic, who saturated with mercurials and iodide of potassium derives no benefit therefrom, but is a living reproach to his physician and burden to himself, simply from want of pure air, nourishment, and tonics. Besides paying careful attention to the nutrition and habits of the patient, it is always well to give iron in combination with mercury in the active stages of the disease. Of the other so-called tonic remedies quinine and cod liver oil are the most useful, to be given as indications for their employment may arise, debility and malnutrition being very common developments during the course of syphilis.

With regard to the employment of specific remedies, it is not uninteresting to remark how short a time it was after the general spread and recognition of syphilis during the last two years of the fifteenth century, that mercury was used in its treatment. In a treatise upon "*le mal Français*" by de Vigo, published in the year 1514, there occurs the following devout recognition of the merits of this drug: "Of all the remedies for syphilis, mercury is the best, and be it well understood that I refer only to those remedies which have been employed up to the present time. For perhaps the future reserves discoveries which we cannot now foresee, some genius may arise, and happily inspired for the good of suffering humanity, may reveal to us a remedy alone more potent than all others, and this by the grace of Almighty God, who alone heals our miseries and of His infinite mercy, bestows upon us health of body and soul," and in a book entitled "*Nouveau carême de pénitence*" published in the year 1527, there is an entertaining dialogue between Mercury and Guineum, representing a discussion between them as to their respective merits in the treatment of syphilis, in which the palm of victory is awarded to mercury.

As to the administration of mercury, to which drug the remarks of de Vigo are as applicable to-day as they were three hundred and seventy years ago, the

<sup>3</sup>Deutsche Med. Wochenschrift, Nov. 1 and 2, 1884.

<sup>4</sup>Turnowsky, *Reizung und Syphilis*, Vierteljahresschrift, f. Derm. und Syph., 9, 19, 1877.

opinion of those most competent to judge, is that the cutaneous inunction of the drug contained in an ointment is the most efficient method and I think that any one who has seen much of its use in this way, will be of the same opinion. The daily inunction of mercurial ointment is the most troublesome, dirty, public, effectual and trustworthy method in which it is possible to administer mercury in the treatment of syphilis. Besides efficiency, it possesses the merit of sparing the stomach the infliction of being dosed with the drug, which is nevertheless, introduced into the system to the best advantage, inasmuch as it is brought into direct contact with the cutaneous manifestations of the disease. The immediate application of mercury to syphilitic lesions is much more rapid and thorough in curative action, than if the drug is obliged to meander through the circulatory apparatus in order to reach its destination. The inunction of mercurial ointment, however, sometimes irritates the skin to such an extent as to give rise to the development of so-called mercurial eczema, which is not eczema at all, but pustular folliculitis, and in certain cases, this irritant action renders its employment impossible. Of late years the oleate of mercury has been extensively recommended as a substitute for mercurial ointment, but with regard to this preparation, I can only say that I have repeatedly used it, both for purposes of general inunction and local application, always to find it decidedly inferior in efficiency to mercurial ointment, so much so that I have abandoned its use altogether in the treatment of syphilis.

Notwithstanding the fact that in ordinary cases the employment of mercurial inunction is for various reasons often impracticable, and indeed not necessary, it is well to remember that where energetic and radical action is wanted, it is the most potent remedy which we can employ.

For the internal administration of mercury, the pill form is the most convenient, and I know of no better preparation for use in this way than blue mass combined in a pill with sulphate of iron or quinine, as recommended by Bunstead. It is efficient, and may be given for a long time without causing irritation of the alimentary canal, being much less likely to do so than other preparations of the drug, such as the bichloride or protiodide. It is needless to say that salivation should always be avoided during the administration of mercury for the treatment of syphilis.

The other specific remedy which we have at our command, namely iodide of potassium, possesses the most astonishing power to relieve cerebral and osteo-scapic symptoms in the early stages of syphilis, and a more curative and not less striking action in the advanced periods of the disease, but the point I wish to convey with regard to it, is that however wonderful and rapid its action, it is not curative in the same sense as that of mercury. One does not cure syphilis with iodide of potassium alone, and by cure I mean, to prevent return of the disease as well as to relieve its symptoms. If a patient is in need of iodide of potassium he is also in need of mercury, and the enormous doses of the former drug which are sometimes required to relieve symptoms, would not I think, be necessary, if mercury were always administered at the same time. In the grave cases of cerebral syphilis, occurring in the early stages of the disease as well as in older syphilis, where iodide of potassium is of such value, mercury should not only always be combined

with it but continued after the symptoms have disappeared and the iodide of potassium discontinued.

As has already been said, not only do these specific remedies act upon the lesions of syphilis when introduced into the circulation but their action is very much more rapid and effectual when placed in contact with such lesions, and wherever it is possible, it is also advisable to do this in addition to general treatment.

The initial lesion, mucous patches, which deprived as they are of protective epidermis are the most contagious of specific lesions, so-called psoriasis palmaris, and all localized cutaneous manifestations, are particularly suited to local treatment and should in all cases, receive it. The initial lesion itself, which should be treated until all traces of induration completely disappear, and localized cutaneous lesions, as a rule, are best treated by the application of mercurial plaster, which is composed of equal parts of soap plaster and mercurial ointment thoroughly mixed and spread upon cloth. This plaster possesses enough adhesive power to retain it in place, is thoroughly efficient and easy of application. Mucous patches on the tongue and mucous membrane of the mouth should be touched daily with the stick of nitrate of silver, tincture of iodine, or a five per cent. solution of chromic acid in water, which latter I have found to be entirely trustworthy in its action. An excellent application to mucous patches in other parts of the body, is iodoform dissolved in ether, in the form of spray, the iodoform being in this way most intimately applied and in an extremely fine state of subdivision. It goes without saying that before the local application of remedies, any crusts or secretion which may cover the lesions to be so treated, should always be removed. The lesions of so-called psoriasis palmaris sometimes persist with extraordinary tenacity, and it is a good plan, in their local treatment, to thin down the thick epidermis which covers them, by the use of salicylic acid plaster before the application of mercurial plaster. This matter of the local treatment of all accessible specific lesions is worthy of more detailed attention than is usually paid to it.

The last point which demands consideration is with regard to the continuation of specific treatment after the disappearance of symptoms. The assumption of its necessity, which forms the basis of the well-known method of intermittent but long continued administration of small doses of mercury, so strongly advocated by Fournier, has received striking confirmation by some recent investigations of Neumann<sup>6</sup> upon the histological changes which occur in the cutaneous manifestations of syphilis. He finds that "with the disappearance of the macroscopic or clinical symptoms of the disease, in no sense do its pathological products also disappear, but that even eight months afterwards there still remain in the skin and its appendages, pathological products in the shape of specific exudation cells, which are to be detected only by the use of the microscope." Commenting upon this fact, he says, "Fournier and others are not so far wrong in retaining patients in observation and under treatment for more than a year's time."

There is good reason for adopting this view of the question, and it is unfortunate that we have no means of telling how long such subsequent treatment is necessary in any given case. The rule of two years after the disappearance of all symptoms, adopted by Fournier, is entirely arbitrary and based upon the results of his great experience. Syphilis, when properly treated

<sup>6</sup> Vierteljahrschrift für Derm. und Syph., 2. Heft., 8. 209, 1888.

can be cured, and the word is used advisedly, in the great majority of cases. Cleanliness, hygiene, tonics, and specific treatment, local as well as general, are the cardinal points of such treatment, in the carrying out of which it is well to bear in mind that, as Dr. Wigglesworth well remarks, "It is rarely sufficient to lay down general rules, in the foolish hope that the average patient may possess by instinct, the knowledge which the physician has been years in acquiring. Minute details are to be taught and to be enforced by frequent supervision."

## A NEW SURGICAL DRESSING FOR WOUNDS.

By S. C. GORDON, M.D., PORTLAND, MAINE.

*Visiting Surgeon Maine General Hospital; Lecture on Diseases of Women Portland School for Medical Instruction.*

REPAIR of injuries takes place most rapidly and completely where the process of nutrition is interfered with the least. Inflammation is always a destructive process and always to be avoided, and never to be invoked in parts where we desire repair to take place. Excess of blood beyond what the nutritive process can utilize, interferes with normal repair. Excess of any portion of the blood acts in the same manner. Consequently effusions of serum in the wound or beneath the united surfaces must necessarily prevent the nutritive process from being completed in the shortest possible time. The germ theory has, in my opinion, no place as applicable to vital tissues. It is only when morbid products, or products capable of becoming so, are allowed to remain in or around such tissues that the influence of "germs" are appreciably noticed. Hence, wounds that have been thoroughly cleansed and are kept so by absolutely thorough drainage, cannot and do not take on unhealthy, suppurative action. By thorough drainage I mean not only deep (underdrains) but superficial drainage. In all cases there must be a certain amount of vascular tension due to needle wounds and strain upon the tissues by tying or twisting sutures, and for a period (varying in time in different cases) a certain amount of effusion of serum in the parts in immediate contact, and whatever will best accomplish drainage from this portion of the wound tends to prevent decomposition in the superficial wound itself.

Mr. Samson Gamgee, in a recent address on wound treatment before the Birmingham Medical Institute, said:—

"Clinical observation and histological research concur in proving that repair is an extension and adaptation of the physiological process of nutrition, against which nothing militates more powerfully than does any cause producing vascular excitement or stasis.

"That the essential fact in Chassaignee's system was the employment of drainage in evacuating purulent collections, but the method has been gradually and most beneficially extended to the *prevention of suppuration* by carrying off serous effusions. These, if retained, are liable to decomposition, and by mechanical tension and nerve irritation are potent causes of *inflammation*, which is *opposed to healthy nutrition and repair*, and is the prime factor in the chain of pathological events leading to blood poisoning and death."

Experience has demonstrated that, however carefully we may apply our drainage tubes to the deep portions

of the wound (underdrainage), we find often times, more or less swelling of the edges of the wound, and, if sutures are retained more than two or three days, inflammation and suppuration take place, with failure of primary union, or at least some suppuration at the suture holes. The stasis and tension, due to strangulation of the tissues by the sutures, produces an amount of effusion sufficient to become a focus for decomposition and inflammation. In short, while we have provided for underdrainage, we have omitted to properly provide for *surface drainage*.

Within the past year it occurred to me that if glycerine could be properly applied, we had the desired factor for the production of surface drainage. The well known property it possesses for draining and depleting tissues is demonstrated by every gynecologist who is daily using it for vaginal packs. Its strong affinity for water causes the rapid exosmosis of serum from the vessels with which it comes in contact, and at once relieves them of any excess which may exist. Recognizing this property I made the following trials, with the results given below:—

CASE I. W. G. J., age about fifty-five. Operation for extensive varicose veins, cutting down upon vein, ligating with catgut and closing wound. I made at least seven incisions, involving the leg from ankle to six inches above the knee, incisions averaged an inch in length. After sponging the wounds thoroughly with water, as hot as could be borne by the hands, I squeezed out pads of absorbent cotton from the same water, and then saturated them with glycerine and applied them to each cut; over this dry cotton, and banded over all; no redressing for four days, when all sutures were removed and each cut was entirely healed without even a blush around the suture holes, or a drop of pus. From each pad a large amount of water ran for two days, saturating the bandages even. There was no further trouble from any one of the wounds, so that within a week we were able to put on an elastic stocking.

CASE II. Amputation of the hand on a man seventy-one years of age; caries of bones of wrist; point of amputation four inches above wrist joint. The same course was followed during amputation, and the same dressing applied. At the end of four days, in presence of Dr. John Buzzell, who assisted at the amputation, it was dressed for the first time, and much to our gratification we found the most perfect primary union, without a tinge of redness or drop of any kind of discharge.

CASE III. Amputation of breast in a lady sixty-four years of age. The patient was a very large, fat woman, requiring an extensive wound for removal of the entire gland, at least twelve inches in length. Dressing remained four days, and, on removal, all the sutures were removed, leaving the wound, as each of the others had been, entirely dry, and closed throughout. Not the slightest elevation of temperature occurred or signs of redness about any portion of the wound.

The next cases were three cases of Tait's operation for removal of the uterine appendages, all made within two weeks. Through my own neglect to inform my assistant just how to prepare the pack in one case, it was not dipped in the hot water, but the dry cotton was saturated with the glycerine and consequently it was not so readily taken up by the cotton, and an excess of glycerine remained on the surface. This, by its absorbent power on the skin, with which it came in

contact, produced a slight dermatitis, but did not interfere with union of the wound. It is quite common in cases of abdominal section to have small abscesses form around the suture holes, and become very troublesome from the pain and discomfort, which last sometimes for weeks. In neither of these three cases has there been the least trouble in that respect. I feel very sure the exemption is due to the removal of all serum, produced by tension of the sutures.

The glycerine used in all the cases given above, with one exception, was what is known, in commerce, as "common glycerine." I use this in all gynecological work, and for the past few years have dissolved in each pound and a quarter of glycerine half an ounce of boric acid. This I happened to have with me when I made my first trial, and have used the same each time since, with the exception named, when I used a much stronger solution of the acid. If any one should claim that the effect produced is due to the antiseptic virtue of the boric acid, he will claim more for a two and one-half per cent. of the acid than any one has yet believed it possessed. I shall use glycerine alone at the next trial, and shall expect equally good results.

In conclusion, I can only ask the profession to give this a trial, each man for himself. I have never yet used, either in public or private practice, the so-called germicides, believing that in vital tissues no such dangerous remedies are called for, and that the well authenticated cases of poisoning by them outnumber the well authenticated cases of septic poisoning which have occurred from neglect of their use. Even the most careful Listerism does not prevent the latter result. In my opinion, if we get rid of the effusions and prevent the exudate, we will surely have primary union. Certainly, the records of Tait and Keith in abdominal surgery, cannot be equalled by any follower of Lister. In my own experience I have had eighteen consecutive Tait operations without a death, and but one case where there could by any possibility be a suspicion of septic influence, and in that case the parotid glands were inflamed for a day or two only. Forty-three abdominal sections (including the oophorectomies) with thirty-six recoveries, justify me in believing that no better results can be expected, where all the deaths but three were malignant cases. Of the three non-malignant cases, one only died from any cause that the most ardent follower of Lister would have claimed could have been prevented, by the use of the spray and other "antiseptic precautions." In the case of hysterectomy for a large uterine fibroid, the patient had become completely anæmic from repeated exhausting hæmorrhages, and had I the same condition of things again, I should make Tait's operation instead of hysterectomy. She died in thirty-six hours, from peritonitis. The other two cases lived only twenty-four hours, and died from shock, and (perhaps in one case) from internal hæmorrhage. I feel quite sure had I the same cases to operate upon now I would save them all.

— A physician was fined at Oswego, last week, \$250, with the alternative of six months' imprisonment for contempt of court in refusing to testify in a criminal case. He pleaded, unwillingly, as a defence that his testimony would involve the disclosure of professional secrets.

## DILATATION OF THE UTERUS.—A CONSIDERATION OF SOME OF THE METHODS AND THEIR VALUE.<sup>1</sup>

BY F. H. DAVENPORT, M.D. BOSTON.

*Assistant in Gynecology, Harvard Medical School.*

THAT the uterine canal should sometimes be dilated for purposes of diagnosis and treatment, no one now-a-days denies. All are agreed that there are cases which imperatively demand, that not only instruments, but the exploring finger of the operator, should be introduced into the uterus. To make such introduction possible, some dilatation is in the majority of cases necessary.

The indications for this procedure are becoming fixed. Considerable difference of opinion still exists, however, in regard to the manner in which such dilatation should be effected, and it is with the hope of throwing some light upon the question, and of eliciting some discussion on mooted points, that this short paper is written.

Looking at the matter broadly, dilatation of the uterus is employed in two general ways: first, as a means to enable the operator by instruments or by the sense of touch, to make a diagnosis, or to carry out treatment, and second, as an end, the stretching itself being the object sought. In considering dilatation as a means, the question as to the method to be employed, narrows itself in general, to the discussion of rapid or instrumental dilatation, and slow dilatation, or that by means of tents. One can be accomplished in from five to twenty minutes, the other in from twelve to twenty-four hours. Both have been practiced for a long time, and both have their strong advocates. Of late years, the rapid method, has been on the whole gaining ground, and it will be part of our object to discover, if we can, how far the growing preference is justified by the merits of the case. In determining this point we will look at the methods from two different standpoints: first, as regards their safety, second, their efficacy.

I think there can be no doubt, that on the whole, rapid dilatation by means of instruments, is the safer method. Let the same operator exercise equal care in the employment of both modes of dilatation, and in a given number of cases done in each way, there will be fewer complications and unpleasant accidents by the rapid than by the slow method. This seems to me to be due to the fact that there is one danger connected with the use of tents which is peculiar to it, I mean that from septic infections. This danger, to be sure, can, by the exercise of due care, be reduced to a minimum, but it is a factor which cannot be wholly eliminated even with the most scrupulous observance of antiseptic precautions, and in the comparison of the two methods, should be taken into consideration.

Were there no counter-balancing circumstances, this fact should lead us to abandon the slow method entirely; but as will be seen later, when speaking of the relative efficacy of the two modes of operation, there are cases in which we are warranted in running the slight extra risk, in view of the better results obtained.

I would not be understood as claiming that the rapid method is absolutely free from danger. There are, of course, the risks incident to any operative procedure on the uterus, risks which are often impossible to foresee. There are cases in which the slightest interference is followed by inflammatory reaction. These accidents are not, however, to be charged to the method employed. I can, however, conceive such

<sup>1</sup> Read before the Obstetrical Society of Boston, November 11, 1885.

force being used as to tear into the structure of the uterus itself, and in this way start a cellulitis. But with a proper instrument, and due caution in its use, such an accident would hardly happen. There is a class of cases which I shall speak of later, in which it is difficult to get complete dilatation with the instrument. In these, cellulitis may occur, but I should feel it was more likely to be due to attempts to introduce the finger, with inadequate dilatation, then to the stretching itself. Safety is promoted by having a free open canal, so that the finger can pass in easily.

The danger from septic infection by tents being recognized, it can be lessened by a proper selection of the kind employed, and then thorough disinfection. Under no circumstances, in my opinion, should sponge tents be employed. However carefully prepared, and however antiseptically introduced, they so favor septic poisoning, that they should be entirely discarded in favor of less dangerous forms. Fortunately we possess in laminaria and tupelo all that we need. The chief advantages of the laminaria are its smooth surface, which admits of its easy introduction when the canal is small, and its great expansive power. The advantages of the tupelo are that it swells more quickly and more uniformly than the laminaria and softens the tissues more thoroughly, thus resembling the sponge tent in its action. As it can be procured of much larger sizes than the laminaria, it is better adapted for more thorough dilatation. Bearing in mind the peculiar advantages of each, it will be a matter of experience to choose the appropriate tents for the individual case.

The second ground of comparison of the two methods is, as regards their efficacy. Which does its work best, rapid or slow dilatation? This question cannot certainly be answered definitely off-hand in favor of one or the other. The kind of patient, the history and nature of the case, the character of the uterine tissues to be stretched, and the object of the dilatation, must all be taken into consideration before the best method can be decided upon.

In the first place, where only moderate dilatation is desired, as is the case where applications are to be made to the interior of the uterus, and free drainage is essential, or where it is necessary to use the curette for the removal of hyperplastic growths, the rapid dilatation by graduated sounds, or by some dilator, is all that is called for. For such purposes, tents need never be used.

Suppose, however, it is desired to dilate sufficiently to allow of the introduction of the finger. In such a case, other considerations come into force. Uteri differ very much in the ease with which they yield to a force applied in this way. It fortunately happens that in a majority of cases in which we wish complete dilatation, there has been more or less persistent hemorrhage, or leucorrhœal discharge, both of which tend to render the tissues of the cervix more yielding. Such is the fact in cases of abortion, where we wish to remove retained products of conception; in hyperplastic endometritis, in polypus, and in many cases of malignant disease. In the case of fibroids, however, especially the interstitial and subserous varieties, which are usually accompanied by less hemorrhage, such softening is not likely to take place.

The uterus which has been repeatedly or recently the seat of pregnancy, will dilate more easily than the virgin uterus, or where it has undergone senile atrophy.

The examination of the patient will throw some light upon the question. If we find on digital examination that we have a hard, indurated, conical cervical portion, and the passage of the probe shows a narrow unyielding os internum, we should doubt the wisdom of relying upon rapid dilatation alone.

Even with a cervix of apparently normal consistency, it is, in my experience, not infrequently a difficult matter to stretch the uterine canal sufficiently, with the ordinary dilators, to readily admit the passage of the finger. The usual instruments do stretch the internal os wide enough to admit the finger could the calibre attained be kept; but as soon as the instrument is withdrawn, the elasticity of the tissues, contracts the canal again. Here is where a tent becomes of great service. By its prolonged action it both paralyses the muscles, and softens the tissues.

The conclusions arrived at from the consideration of these various points, are that in the large majority of cases in which we are called upon to explore the interior of the uterus, rapid dilatation will suffice; in a few cases, usually unmarried women, with firm unyielding uterine tissues, where there has not been much hemorrhage, it will fail. The danger in such cases is that in attempting to force the finger through the imperfectly patulous canal, such violence is done to the uterus or its surrounding parts, that inflammatory action is set up in the neighboring cellular tissue. To avoid that danger in this class of cases, my plan of treatment would be the following: I should first introduce with all the caution possible, a tupelo or laminaria tent, using the latter if the canal was very much contracted. This I should allow to remain for six or eight or at the most twelve hours, the patient being kept absolutely quiet in bed. Then under ether I should remove the tent, wash out the cavity with a solution of corrosive sublimate 1-2000, and complete the dilatation with instruments.

In must be borne in mind that this mixed method of dilatation, if I may so express it, would, however, only be necessary in a very small majority of cases, and in view of the slightly increased risk which I consider inseparable from the use of tents, I should employ it only when I consider it absolutely essential to success.

This method as compared with that by tents alone, using two sets in immediate succession, has a marked advantage in that it is less painful. The introduction of a single tent, especially if the canal is narrow, and tortuous, is an exceedingly painful operation. Add to this the constant pain as the tent swells, then the forcing of several tents into the already sensitive uterus, with the woman exhausted with the suffering she has already gone through, and it is no wonder that the patient comes to the final examination under ether, weak and predisposed to septic infection. I have seen nausea and vomiting, chilly sensations, and a variety of other symptoms occur as a result of this course of action.

We now come to consider the second class of cases in which we employ dilatation, not as an aid to diagnosis, or for further treatment, but as an end in itself. This is done principally for the relief of stricture, the usual symptoms of which are dysmenorrhea and sterility. It has also been recommended in cases of antelexion. Here the comparison as regards the method of operating, is to be made between the so-called bloody dilatation, or that by means of cutting

with a knife or scissors, and the bloodless, or that by stretching.

My own experience in these cases, has been, until recently, wholly with the former method, namely, that by cutting, nor can I say that on the whole I have been disappointed with it.

There has been, if I remember rightly, in a series of cases which must number at least two hundred, occurring both in private practice and in the Free Hospital for Women, one or two cases of cellulitis following it, and a small number where there was failure to relieve the symptoms. But on the whole it has proved satisfactory. Within the past six months, influenced largely by Dr. Goodell's warm advocacy of the operation of divulsion, which he was led to adopt after two fatal cases by the other method, that has been tried. The operation itself has been unaccompanied by any unfortunate occurrence. In two or three cases there have been high temperatures following, and in one case some cellulitis.

As to the ultimate results, it is too soon to speak definitely. Enough time has not elapsed to show whether the symptoms for which the operation was done, have been more than temporarily relieved. A case which occurred at the Free Hospital for women, will be of interest in this connection. The patient entered the hospital three years ago, complaining of great dysmenorrhœa. It was found that she had a stricture at the internal os, which was incised in the usual way. The operation was apparently successful, as the patient was entirely free from pain at the menstrual period, for several months. It gradually returned, however, and she was readmitted to the hospital in January of this year. It was found that the canal had again contracted. This time the operation of divulsion with Ellinger's dilator was performed with an equally good result for the time being. A letter received a few weeks since, says her monthly periods are still painless. It will be of interest to learn whether this improvement remains permanent.

My own impression is that divulsion has not so much in its favor, or rather that incision of the cervix is not so dangerous a procedure as Dr. Goodell claims. If the latter operation is done carefully, the patient being kept in bed at least a week, and the danger of hemorrhage and of an immediate closing of the canal to its former calibre being guarded against by the introduction of a tent of styptic cotton, I do not believe the risks any greater nor the results any less certain, than from the operation by stretching.

The points discussed in this paper may be briefly summed up in the following propositions:

- (1) Dilatations for diagnosis or for farther treatment may be either slow (by means of tents), or rapid (by means of instruments).
- (2) Rapid dilatation is in general safer than slow.
- (3) The principal danger of slow dilatation is from septic infection. By strict antiseptic precautions, this danger can, however, be reduced to a minimum.
- (4) For moderate dilatation the method by instruments will always be found satisfactory.
- (5) In cases where full dilatation is necessary, (to introduce the finger or to remove a tumor) it will sometimes be found that the rapid method will not give the complete relaxation desired, and the risk from attempting to explore with imperfect dilatation, is greater than that from the use of tents. In these cases tents should be carefully used.

(6) Sponge tents should never be employed. Tupelo and laminaria are safer, and will answer every purpose.

(7) The preliminary use of tents followed by stretching with instruments is safer than the employment of two sets of tents in immediate succession.

(8) In enlarging the canal, in cases of stricture or flexion, the choice lies between the so-called bloody method, that by cutting, and the bloodless, that by stretching.

(9) The claims made for the operation of divulsion of greater safety and equal or greater efficacy, have not become established; a longer time is needed before a decided opinion can be given.

## Reports of Societies.

### BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

E. M. BUCKINGHAM, M.D., SECRETARY.

DECEMBER 14th, 1885, the President, Dr. F. W. DRAFER, in the chair.

DR. JAMES C. WHITE showed a case of

#### MELANOSIS LENTICULARIS PROGRESSIVA.

which he preferred to the name *angina pigmentosum* et *atrophicum* proposed by Kaposi, who was the first to observe the disease. Including the present and one other case, a brother of this one, now under Dr. White's observation, there have been in all but thirty-five cases reported, occurring in thirteen families, and seen by nine observers, showing the disease to be of great rarity. The disease begins in infancy or childhood with an apparent freckling of the hands and face, which afterwards so increases as to cover the whole surface, the freckles being lenticular pigment spots. Later new blood vessels form in the skin, showing as minute points. After this, comes atrophy, of the pigment, accompanied by a thinning of the epithelium and of the corium. In about one-half the cases the disease has gone on to hypertrophy of the papillæ, followed by carcinoma of the skin, and death.

The case shown to-night is a Russian, seventeen years old, whose skin has been diseased since he was two. The skin, which is atrophied, looks like that of a negro who has lost a portion of his color in parts. There is neither hypertrophy nor carcinoma. The patient, who has had the disease fifteen years, is well formed, and has healthy functions. In a small proportion of the cases is a want of development of mental powers, the connection of which fact with the presence of the skin disease is not obvious.

To questions by members, Dr. White answered that although the disease appears, as stated, to select certain families, yet that there is no evidence that it is hereditary. This patient is the child of healthy parents. The cause is apparently not to be found in the hygienic surroundings.

LITHOLAPAXY.

DR. A. T. CANOR reported two cases, and showed the crushed stones. The first patient was a man of sixty-seven, who had been referred to him by Dr.

Reynolds. He had had symptoms for a year and a half, and during nine months had had blood in the urine, and difficulty in walking or riding. The stone was easily detected, but, being a hard uric acid calculus, was not so easily broken. A large fragment lodged in the tube, and, as it proved impossible to dislodge it, it had to be drawn out through the urethra, causing considerable laceration. The patient was a drinking man, getting a pint of brandy or whiskey in a day, and to this Dr. Cabot attributes much of the subsequent history. At the end of twenty-four hours, the temperature rose to 102.5, and by the next day to 104.6, and the patient was delirious. There were swelled testicle and a dry tongue, but no hardening about the bladder. There were tremulousness and jactitation. At this point the six ounces of brandy that the patient was getting were increased to twelve, and he began to improve. He is now well.

The second case, a man of forty-seven, with a small uric acid stone, was remarkable for a long tight prostate, making the reach for fragments hard, and increasing the time of operation from fifteen minutes, which would have otherwise been necessary, to twenty-five. He also has made a good recovery.

A third case was interesting for the lesson it teaches as to the value of antiseptics. A forty-grain prostatic stone was crushed November 10th, and the patient made a good recovery, with no reaction. Eight days later he was pumped out again, according to routine, before leaving the hospital; no more fragments were found, but the speaker did not personally see to the disinfection of the evacuator, and believes that it was not well done. On this occasion the temperature went up to 100.5 and there was an increase of mucopurulent matter in the urine.

DR. FRANCIS MINOT read a paper on

#### CASES OF ABDOMINAL DISEASE, WITH OBSCURE DIAGNOSIS.

DR. HENRY I. BOWDITCH asked to be allowed to read a brief record of Dr. Minot's second case, in which an exploratory incision had "been suggested by two physicians." Dr. Bowditch said that he was one of them, and, under similar circumstances, he was prepared to give the same advice. He then stated that though he could not find any tumor in Dr. Minot's case, the long continued ill health, severe dyspepsia, and at length such horrible paroxysms of pain, that the patient rolled on the floor in his agony, and his evidently failing strength proved to Dr. Bowditch's satisfaction that the patient would die unless relieved. Medicines had been used in vain. Drs. Bowditch and Marcy, therefore, advised an exploratory incision, because life was intolerable as he was, and with modern surgery an exploratory incision had been done many times without danger.

The following case had much weight with them in making this suggestion. Dr. Bowditch had been asked to see a patient in consultation with Dr. Marcy, December 23, 1883; a woman aged fifty-three. She had been healthy till October 7, 1883, when she was suddenly seized with severe pains around the waist, preventing easy breath, and increased by motion. At first there was lessened respiratory murmur in the lower part of the left lung, but that had been relieved, and the thoracic organs were healthy. In a few days, very deep jaundice ensued, with clay-colored dejections and urine dark colored, but otherwise well. Dr. Marcy

saw her first December 10, 1883, and Dr. Bowditch was called in consultation thirteen days afterward, that is, on the twenty-seventh day of the disease, and not long before he saw Dr. Minot's case. A few days before that, she had shown signs of mental disturbance, loss of memory, slight incoherence in talking. At Dr. Bowditch's visit she was crying like a child, and very restless, evidently in great pain. She needed assistance in moving about her chamber, but there was no paralysis. She refused food. Pulse 76. The cephalic symptoms increased, and she died in twenty-four hours. At the autopsy, the sole trouble found was a gall stone of the size of a marble, impacted in the common duct. It was manifest immediately on opening the abdomen, and was considered the cause of her suffering and death, and the question arose in the minds of both whether life would not have been saved by an operation and removal of the calculus. The ducts of the liver were all very large, and some old adhesions were around the gall bladder, otherwise no lesions.

Dr. Bowditch believed that an operation might have been done in this case, and in Dr. Minot's case of ulcers of the stomach. Dr. Bowditch had nothing to regret in advising the same exploratory operation. He believed that within fifty years a surgeon will be deemed wanting in duty to his patient if he does not propose an operation in cases of intussusception, obstruction of the appendix caeci, etc. He saw no reason why some ulcers of the stomach, even, may not be excised if need be, and the adjacent parts be brought together by sutures.

DR. E. N. WHITTIER said it is extremely consoling and not by any manner of means of necessity discouraging to those whose experience is comparatively limited, to have so accomplished a clinician as Professor Minot, declare as definitely as he has in his paper to-night, his opinion of the difficulties of dealing with diseases of organs within the abdominal cavity, particularly with reference to the obstacles constantly met with, standing in the way of accurate and satisfactory diagnosis.

Several years ago, while attempting to collate the methods of various teachers for the purpose of tabulating and formulating a method to be used in instruction in clinical medicine, I was much impressed by the wide range of apparently collateral subjective and objective symptoms, cited by these various authorities, and quickly found that any tabulation, comparatively comprehensive, became at the same time too extended and cumbersome to be of much value for the purpose I had in view. Of late, therefore, I have restricted myself to the admirable table of Professor Roberts, whose division for the purpose of diagnosis into eight groups is sufficiently suggestive to prevent any essential error of omission.

The table is as follows:

1st. Diseases of the abdominal walls.

2d. Diseases of the peritoneum and its folds.

3d. Diseases of organs within the abdominal cavity, namely: stomach and intestines; hepatic organs, including the liver, gall bladder and ducts, spleen; pancreas; supra-renal capsules; urinary apparatus, including kidneys, their ducts and the bladder; female generative organs, including uterus, broad ligaments, fallopian tubes and ovaries, and last, though not least, the absorbent glands.

4th. Diseases of blood vessels, especially the aorta and iliac arteries.

5th. Diseases of sympathetic and other nerves within the abdominal cavity.

6th. Diseases originating in connection with cellular tissue, such as inflammation and abscess.

7th. Diseases springing from posterior boundaries of the abdomen, from the pelvis and the structures within its limits, or from the diaphragm, and invading the abdominal cavity.

8th. Diseases encroaching upon the abdomen from other parts, especially from the thorax.

I do not feel that I can add anything to the interest of this meeting by citing cases of similar import to those reported by Dr. Minot, or by any remarks upon the subjects embraced in his valuable paper.

I have therefore chosen to make this effort to re-inforce what he has so well remarked upon, concerning the difficulties of diagnosis and treatment in diseases of the abdominal organs, by the reference to which I have asked your attention in the table just quoted, to similar opinions advanced by other eminent teachers in other schools, both in this country and abroad.

DR. F. B. STEPHENSON, of the Navy, present by invitation, mentioned a case of obscure tumor which was observed in another city, and which puzzled more than one practitioner, but which readily disappeared on using a cathartic.

DR. MINOT said that he must acknowledge that he had been mistaken in supposing that Dr. Bowditch had felt the tumor. He had not been mistaken, however, about the other gentleman, who had tried to point it out to him.

DR. GEORGE H. TILDEN read a paper on

#### SOME POINTS IN THE TREATMENT OF SYPHILIS.

DR. J. C. WHITE said that if there were a criminal law, prohibiting the treatment of syphilis before the appearance of secondary symptoms, it would be a gain to the community. There are few physicians capable of making a diagnosis at that stage; and many patients are dosed for a syphilis that they never had, and go through life anxiously watching for its reappearance; a serious penalty for having consulted an unwise or a dishonest practitioner. There is nothing to be gained by so early treatment, although theoretically, if a bacterial origin for the disease should be demonstrated, it would seem that the earlier it were attacked, the sooner it would be destroyed.

The speaker does not by any means always give mercury and iodide of potassium together in the later stages, but in a large proportion of them gives iodide alone. Its action seems at such times almost miraculous, and it is hard to see how anything could make it more rapid. Unfortunately its benefits are not permanent, and for this reason he follows it with mercury. As one gets older, he learns to place less absolute confidence in either mercury or the iodide, and in the graver forms of the disease he has not now the confidence he once had that he will be able to relieve the patient in every case, and to keep him relieved.

The speaker said that the use of tonics in connection with mercury depends on the condition of the patient. If he is well nourished, they are not needed as a rule, although there are cases in which they are all important.

DR. F. B. GREENOUGH, wished to emphasize the statements just made, as to the wickedness of giving syphilitic treatment in many cases during the early

stage, where it only serves to mask the diagnosis. He does not agree, however, with Dr. White, that a diagnosis is rarely possible, but sees many cases in which he has no doubt at all. If in these cases treatment is indicated, as by a deep or large ulcer, or by the need of concealment or of avoiding danger to others, then he would use specific treatment with local treatment, and the good result has been clinically most marked. As a rule, however, specific drugs should not be used at this time.

The treatment by inunction is the most thorough and quick, but it is the most disagreeable and severe. If the ointment is made with petroleum instead of lard it is less likely to irritate the skin. He has not felt like continuing the use of blue mass for a long time, but generally prefers the protiodide.

It is impossible to fix on a time when a patient will be cured. Formerly, as the result of long experience, has somewhat arbitrarily chosen two years for the treatment. Keyes has lengthened his treatment by a year. Some patients will be as well in a short time as others are in a long one. That a large number are really cured, there can be no question, but, on the other hand, there are a certain number of relapses. The speaker believes that notwithstanding these difficulties, a prognosis as to return of symptoms can be approximately given. If the disease has run its course in a simple, orderly manner, and has then disappeared, and if it has been well treated for two years and has then been under observation for one year without relapses, that particular patient is probably well.

The speaker agrees with Dr. White about tonics, iron, quinine, or cod liver may upset the stomach, and interfere with the treatment. They should not be used as a routine.

DR. J. B. AYER mentioned a case of syphilitic swelling of the nose, which only slowly diminished under the use of mercury in six months, until, by advice of Dr. Greenough, he had used inunction, when it disappeared in four or five days.

DR. EDWARD WIGGLESWORTH said that he took the side of the reader with regard to tonics, as he regarded syphilis as a wasting disease, characterized by the formation of imperfect material which rapidly degenerates. Mercury has been supposed to be a tonic. Sigmund had thought that with tonics and no mercury, he could get as good results as with mercury, but without tonics and hygiene. He himself thinks that hygiene, tonics and cleanliness are of the utmost importance, and he always employs them from the beginning. The stomach is almost never disturbed by Bimstead's pill of mercury, iron and opium, and as symptoms go off, it is common for patients to say that they never felt so well in their lives. He thought that the want of confidence mentioned by Dr. White might be owing to his neglect of tonics. He himself prefers to treat for three years, with breaks of a month in the second, and of two months in the third year, the intermediate treatment being of one month's duration.

DR. WHITE said that he did not see how Dr. Wigglesworth could compare their results. What data had he upon which to form an opinion?

DR. WIGGLESWORTH said that he judges from Dr. White's own statement as to relapses. For his part, he seldom had relapses after the course was finished, and thought they might have been perhaps prevented by the use of iron.

## PROCEEDINGS OF THE OBSTETRICAL SOCIETY OF BOSTON.

C. M. GREEN, M. D., SECRETARY.

NOVEMBER 14th, 1885, the President, DR. A. D. SINCLAIR, in the chair.

DR. F. H. DAVENPORT read a paper on

DILATATION OF THE UTERUS: A CONSIDERATION OF SOME OF THE METHODS AND THEIR VALUE.<sup>1</sup>

DR. BAKER corroborated what the reader had said in his paper: he also exhibited a set of dilators, which he had devised several years ago, for rapidly dilating the uterine canal.

DR. J. W. ELLIOT said if only one tent is to be used, it should be as large as possible; but it is difficult to know how large a tent the cervix will admit without trying several, and this causes a waste of tents. He therefore thinks it best to measure the capacity of the cervix with Hank's dilators, and then select a tent of proper size. He had recently read in the *Berliner Klinische Wochenschrift* an excellent method of making tents aseptic: the tent, either laminaria or tupelo, is soaked in a ten per cent. ethereal solution of iodoform. Of course this causes the tent to swell; but the rapid evaporation of the ether, after the tent is removed from the solution, causes the tent to shrink again to almost its original size. Subsequent section of a tent thus treated shows crystals of iodoform in its interior: such a tent must therefore be thoroughly aseptic. Solution of corrosive sublimate may also be used for this purpose.

DR. C. P. STRONG said that he had been led by the recent favorable reports of Dr. Goodell to employ rapid dilatation in four cases, in which formerly he should have used either the knife or tents. Of these, two were cases of sterility with long narrow cervixes and stenosis of internal os, the finest probe entering with difficulty. Each case was also marked by considerable dysmenorrhœa, which has entirely disappeared since the operation. The canals still remain freely open, admitting, without pain or hemorrhage, a sound three-eighths inch in diameter, although since the operations, five and six months respectively, no dilating instruments have been introduced. In the third case the cervical canal was so completely plugged by cicatricial tissue from the employment of caustics, that a probe could not be passed. The symptom for relief in the case was intense dysmenorrhœa, and incidentally sterility. By the operation the dysmenorrhœa was entirely relieved, except some little ovarian disturbance. Dilatation was very difficult owing to the yielding cicatricial character of the tissues, and a unilateral laceration occurred which healed perfectly, however, in a fortnight. Rapid dilatation was employed in the fourth case for exploration of the uterine cavity and immediate treatment by curetting. After an interval of two months the operation was repeated in this case.

The advantages gained by the method of dilatation in these four cases were: Entire absence of subsequent febrile disturbance; absence of danger from immediate or secondary hemorrhage; and, most important of all, permanent patency of the cervical canal. It had been the experience of the speaker that the stenosis of an incised canal returned almost invariably, unless dilators were frequently passed, thus practically keeping the patient under active treatment. He has especially noticed this fact in his out-patient service from the fre-

quency with which patients presented themselves because of more or less complete return of the old symptoms, dysmenorrhœa, etc., which had been temporarily relieved by incision of the canal. The speaker had used a modification of Ellenger's dilator made by Gemrig, but, except in the fourth case, where the cervix was softened by hemorrhage, this instrument was not sufficiently powerful to dilate to the necessary extent for digital exploration, as the blades feathered badly.

DR. SINCLAIR made the following remarks on

## PROLAPSE AND PROCIDENTIA UTERI, AND ON A MODIFICATION OF ZWANCKE'S PESSARY FOR THEIR RELIEF.

We are frequently consulted by elderly women who have borne children, and occasionally by the nulliparous, about some sort of protrusion at the vulva, which causes them great distress or inability to walk or stand for any length of time. This trouble is described by them as having been coming on for a long time, years may be, and increasing in the amount of discomfort it entails, especially on the bladder. An examination with the patient lying on her back, will not give a satisfactory exhibition of the disorder, but rather have the woman walk about the room, or go up stairs and down, and then be examined in the erect position, when the nature of the protrusion may be readily ascertained. It will be found, generally, that the anterior wall of the vagina protrudes to a greater or less degree, in some cases; while in others the sagging of the anterior walls of the vagina has close behind it, and near the vaginal outlet, the cervix of a retroverted and oftentimes flabby uterus.

Another class of cases presents a still more advanced condition of prolapse, that in which the posterior wall of the vagina is found bulging at the vaginal orifice. This last state of things but precedes procidentia when the uterus slips from the vaginal outlet, carrying with it the vaginal walls as its covering, and causing more or less deflection of the uterus and base of the bladder. I will not attempt to give a detail of the causes which lead to this hernia; nor shall I refer to other conditions which give similar discomfort to their subjects. My object is to introduce to you certain disorders which have been benefited to an unexpected degree by an instrument which I shall show you this evening, and to which my attention was called six or seven years ago by Dr. Erich, of Baltimore. It is a modification of Zwancke's pessary, and consists of a stout copper ring covered with rubber and formed into a figure-of-8 pessary with a short nib or stem, the latter not more than half the length of that of the original instrument. It requires a little manual dexterity to twist this ring into a proportional figure-of-eight shape; but a little practice will surmount what little difficulty there may be. There are one or two objections to the use of this instrument: one that but few patients are able to remove and replace it; another, that it may be a barrier to conjugal relations. The first of these has been overcome in one or two instances, showing that the feat is not impracticable: I do not bring forward this instrument as a cure-all, as other forms of pessary have succeeded at times—even the common stiff Meig's ring has done wonderfully well in some cases. I am forced to say, however, that in my own practice I have had no great success in affording relief in the kind of cases which I now speak of, before the use of this modification of an old pessary. Not to be tedious; yet I ought to say that certain preliminaries are nec-

essary before inserting the instrument. If the prolapsed parts are merely pushed back into the pelvis by main force, one is not certain that the reposition is complete. To insure which, in some cases, the patient is made to assume the knee-elbow position, and the uterus, by the aid of the pneumatic pressure from the vagina, made to swing in the abdomen, or if this manœuvre will not effect a perfectly free condition of the parts, the uterine sound may be used. Having thus prepared the parts by a complete reduction of the hernia, a pessary of suitable size can be introduced, which keeps its position and prevents recurrence of the prolapse.

I will not undertake to explain, if I could, the way in which this pessary holds its place in the vagina, whether partly by resting on the rami of the pubes, or partly by friction, but that it does retain its position is certain.

The first case in which I tried this instrument was that of a lady sixty-three years of age, with complete prodiscentia, who after many years of suffering and discomfort had the great satisfaction of being entirely relieved; the uterus never afterward appearing externally. She passed through a severe attack of bronchitis two or three years later. Unexpected success in this instance, encouraged one to try its use in others similar, but most frequently in the earlier stages of prolapse as these present themselves oftener. Of all degrees I have treated fifteen to twenty cases with satisfactory results. I can scarcely recall a failure when the patient was willing to do and be done by, all that was best for her. It may be that this is but another and ephemeral notion to be added to the legion of those that have had their day and gone to the limbo of the forgotten and discarded, but it will then have done some good in its short day, and I am, perhaps, its only herald. It may be asked, how long is the instrument to be worn? How long is a truss for inguinal hernia to be worn? I answer: Certain contingencies apply to the one as to the other. In the case of hernia of the pelvic floor care must be had that the support does not cause ulceration of the parts which overlie it, and that a detergent wash be used twice or thrice weekly. In this, as in hernia of the groin, a new support will sooner or later be required.

In reply to questions, Dr. Sinclair said that he examined the pessary *in situ* two or three days after its insertion, then in a week, and again in a fortnight; after that, if the pessary was well fitted, the patient could wear it for a long time without examination. He said his pessary was the same as Zvancke's in principle, but that Zvancke's pessary was made of hard material and might therefore do harm; it was, moreover, in most cases not large enough.

Dr. ELLIOT showed some finely colored drawings of a number of small abdominal tumors which he had removed by laparotomy: among them were several dermoid cysts of the ovary, cysts of the broad ligament, one complicated with a papilloma, an inflamed and enlarged fallopian tube, ordinary cystomata, etc. He said he intended merely to show the drawings and not to report the cases. He had given some time and attention to these small tumors, the importance of which he thought was often overlooked. The great difficulty was, of course, in the diagnosis; but Dr. Elliot thought that with patience and care the diagnosis could be accurately made out in almost every case. The great amount of suffering caused by some of these

tumors is not generally known, and when they become impacted in the pelvis the suffering may become intense. They also destroy life in various ways. Dr. Elliot said he happened to have had rather a large experience with dermoid cysts: he had seen them of various sizes and in conditions very unfavorable for the patient. He thought that being of slow growth they often remained in the pelvis for a long time unknown to patient or doctor. There they were the cause of various pathological changes. He had usually found the small ones tightly impacted in the pelvis and universally adherent with more or less recent adhesions, so that with further growth the cyst must have ruptured rather than rise out of the pelvis. He had also seen a case where such rupture had actually taken place, giving rise to encysted peritonitis and rendering the cyst wall so adherent that its removal was impossible. He concluded, therefore, that these tumors so often progressed unfavorably that they ought to be removed as early as possible.

These small dermoids always feel very hard to the examining finger, and can only be distinguished from fibroids of the uterus by making out their independence of that organ. He had never regretted an early operation. His results had been uniformly good. Out of fifteen laparotomies for large and small tumors he had had but one fatal case, and that was in the case of a sarcoma where an exploratory incision was made in the hope of saving life.

Dr. BLAKE said he could testify to the difficulty of diagnosing these small tumors: he was in favor of removing them early, especially dermoid cysts.

Dr. BAKER wished to congratulate Dr. Elliot in his success in removing those small abdominal tumors, a much more difficult procedure than the removal of large tumors.

#### FISSURE OF THE ANUS FOLLOWING PARTURITION.

Dr. MIXOT desired to put on record two cases of fissure of the anus occurring in the puerperal condition. The patients primiparae and healthy, but of nervous temperament. In both cases the forceps were used when the head was in the perineum. The patients did well for about three weeks, then each complained of severe pain, coming on about half an hour after defecation, and lasting several hours. Fissures were found in each case. After the unsuccessful trial of various remedies, the sphincters were forcibly stretched, with immediate and permanent relief.

#### THE NEW YORK ACADEMY OF MEDICINE.

Stated meeting, December 3, 1885.

##### THE WILLARD PARKER HOSPITAL.

THE SECRETARY read a communication from the Health Department, announcing that the new Willard Parker Hospital in East 16th Street is now open for the reception and treatment of cases of contagious disease, and inviting the President and Fellows of the Academy to visit it and inspect its accommodations. It is provided with a resident physician and a corps of trained nurses, and is designed for the treatment of patients suffering from such diseases as scarlet fever and diphtheria, who cannot receive proper care in their own homes.

Dr. MORRIS H. HENRY read a

REVIEW OF THE LIFE OF THE LATE DR. LOUIS ELSEBERG, AND OF THE ADVANCEMENT OF OUR KNOWLEDGE OF DISEASES OF THE THROAT DURING HIS PROFESSIONAL CAREER.

DR. SAMUEL W. SMITH read a paper on

ORIGINAL DEDUCTIONS BASED ON A STUDY OF ONE HUNDRED CASES OF FRACTURE OF THE UPPER EXTREMITIES, EXCLUDING THE HAND.

Nearly half of these cases referred to had been in children under twelve years of age. Of those occurring in children under twelve, twenty-five were fractures of the clavicle, while in patients between the ages of twelve and fifty, only eight had had fractures of the clavicle. Having spoken of the character of fractures of the clavicle observed by him, the deformity in which he attributed in large measure to the action of the subclavius muscle, he went on to that of fractures of the humerus, in describing which he mentioned that he referred particularly to those of the lower end of the humerus, involving one or both condyles, or causing a separation of the epiphysis. In speaking of fractures of the radius, he paid special attention to the so-called cases of Colles' fracture, and referred to the character of the obliquity that was met with in different cases. The kind of apparatus required in any case, he said, would depend on whether the obliquity was long or short. He denominated fractures of the lower end of the radius Colles' fracture only when they were of the long oblique variety. When the fracture was transverse, or of short obliquity, the deformity was easily reduced, and fragments readily retained in position.

In the treatment of fractures of the clavicle, of course a great variety of apparatus had been devised, but those most commonly in use are the Desault dressing, with the axillary pad, Lewis's, Sayre's adhesive plaster dressing, and E. M. Moore's shawl or figures-of-eight bandage. Sayre's method was simple and generally efficient, but the greatest objection to it was the irritation of the skin which the plaster was liable to produce, especially in young subjects; the compression of the fore-arm across the chest also interfered more or less with the circulation, and might cause so much discomfort as to call for its removal. Consequently Dr. Moore's dressing was a step in advance; but neither the Moore or Sayre method was efficient when the seat of fracture was near the inner third of the clavicle, and long oblique. In a case of this kind, he had resorted, with good effect, to a modification of Moore's figures-of-eight bandage, which consisted in making a clove hitch around the arm near the elbow.

More recently he had devised an apparatus of his own, which seemed to possess all the advantages of the other dressings in use, and also some peculiar to itself. In this, the elbow, secured in a leather sling, is drawn inward and backward by means of straps passing to a padded band, which is placed in the axilla of the opposite side and fastened over the shoulder. A boy, in whose case a perfect result had been obtained, was shown, wearing the apparatus, and photographs were also shown which were taken before the latter was applied—exhibiting very marked deformity—and at the conclusion of the treatment.

In fractures of the condyles of the humerus, he said that he was convinced that the active combating of the inflammation, usually manifested in the joint, was the

only safeguard against ankylosis. When but one of the condyles was implicated, the ordinary anterior splint was generally efficient; but where the fracture involved both condyles, constituting what is known as a T fracture, he had found the usual methods of treatment quite inadequate. A varied experience, full of disappointments, in the use of the known splints for the more severe fractures of the condyles, had set him to work to devise a splint with the following requirements:

1. To hold the fragments firmly in apposition.
2. To allow the fore-arm to be flexed and extended, pronated and supinated.
3. To lengthen or lessen the external angle of the arm with fixation.

4. To leave the entire elbow joint exposed for the purpose of making local applications, during the whole time of wearing the splint, without disturbing the latter.

Such a splint he had constructed, and he now exhibited it, consisting of two rods of untempered steel, with ball and socket-joint, and fixation-screws at the elbow and wrist; the rods being secured to the arm and fore-arm by means of plaster-of-Paris bandages. It had long been a mooted point among surgeons, he said, how soon passive motion of the joint should be commenced; some claiming that this should be at the end of a week, and others, not for three or four weeks. For his own part, he thought that the character of the injury, in any given case, should regulate the time for beginning passive motion.

In speaking of the treatment of Colles' fracture, he said that he had also devised a splint of his own, for this; but his experience with it had not up to the present time been sufficiently large to warrant him in expressing any definite opinion in regard to its merits. He said, in conclusion, that he wished to emphatically protest against any splint whatever being left on for a week or more in any case of Colles' fracture. It was his own practice to remove the dressing every other day, and he said that unless this was done, deformity was very likely to result. To illustrate this, he mentioned a case in which a splint was allowed to remain on uninterruptedly for two weeks; when it was replaced by a plaster-of-Paris bandage, which was not disturbed for six weeks. The result was a very bad arm. In the course of the paper, Dr. Smith also reported a large number of illustrative cases occurring in his own practice.

DR. JOSEPH D. BRYANT said that the cause of the deformity in fracture of the clavicle had been the subject of much discussion among surgeons; but in his opinion it depended simply on the fracture of the bone, and not on the action of any particular muscle or set of muscles. He spoke of the difference in the deformity according to the situation of the fracture, and said that he could not agree with the author of the paper that it was due, at least to any great extent, to the action of the subclavius muscle. If in the cadaver the clavicle were fractured and the body hung up, it would be found that the same deformity would result as in the living subject, and, therefore, it seemed hardly likely that it was produced by muscular action.

As to the method of treatment to be resorted to in this fracture, any apparatus that would meet the indications present would secure a good result; though some of the dressings employed, no doubt, had special advantages. The Sayre dressing met the indications, and he had used it frequently, with good results.

The same was true of Moore's, and others. In the same way Dr. Smith's apparatus fulfilled the indications, as far as he could judge of what he had seen of it to-night, and it appeared to have the advantage over many others, of greater comfort to the patient. This was an important point, and altogether he was much pleased with the dressing; so that he should like to give it a trial as soon as an opportunity offered. On account of the lateness, he would not speak on other points touched upon in the paper.

Dr. Smith said that, following Hamilton, he divided the clavicle into three thirds, and that the deformity was always greatest when the fracture was situated in the middle third. As the insertion of the subclavius occurred at this part of the bone, it had seemed reasonable to attribute the more marked deformity here to the action of this muscle.

#### THE REPORTING OF CONTAGIOUS DISEASES.

Dr. C. R. AGNEW presented a resolution, which was unanimously adopted, to the effect that in the opinion of the Academy any judicial action which tends to prevent the early reporting to the Board of Health on the part of the medical profession of cases of contagious disease is contrary to public policy and detrimental to the public health.

### Recent Literature.

*The Science and Art of Midwifery.* By WILLIAM THOMPSON LUSK, A.M., M.D. Third edition. 8vo. 763 pp. New York: D. Appleton & Co. 1885.

The second edition of this well-known work was, with the exception of a few minor changes and corrections, a reprint of the first, the short interval between the two editions precluding any extensive revision. But in the preparation of his third edition, the author has faithfully availed himself of recent contributions to obstetric science in monographic and periodical literature, and drawn, as well, from his own rich experience. Nearly every chapter bears evidence of careful revision, and some subjects have been in great measure rewritten: the volume is thereby enlarged by over sixty pages, and there are twenty-one new illustrations.

While we cannot notice all the new matter of this edition, we wish to call attention to some subjects which seem of especial interest and importance. The author's advocacy of the use of forceps in extraction of the breech, is, perhaps, the most striking innovation. He has formed his opinions in this matter, however, with great caution, and subjected them to the test of his own experience, as well as that of others. In the last edition, preference was given to the blunt hook and fillet when instrumental interference with a breech case was indicated: the use of forceps was only briefly alluded to; but in the edition before us, the author places forceps first in the order of relative value, and then proceeds to carefully point out the objections to, and advantages of, its use. A special forceps for the breech has been devised by Miles; but, as the author points out, such an instrument is not a necessary addition to the usual armamentarium. Good results have followed the use of the ordinary short forceps, and the axis-traction forceps has proved a safe and efficient instrument when the breech is high in the pelvis. The author is careful to point out that "the extraction of the child should not be made an exhibition of strength," and with this in-

junction in mind, it does not seem to us that the procedure can be a hazardous one in careful hands. We are well aware that conservative obstetricians will regard the operation with distrust; but we think that after the highly favorable experience of Tarnier, Budin, Pinard, of Taylor, Lusk, Haake, Truzzi, and others, the procedure may well receive a place among legitimate obstetric operations.

In the chapter on induction of premature labor, Bayers's method of exciting labor-pains by galvanization is briefly described, and its probable utility recognized. The section on the care of the premature infant contains a description of Credé's hot-water enema and Tarnier's couveuse, both of which contrivances have proved of great value.

The chapter on Cesarean section has been enriched by a brief description of Kehrer's and Sünger's methods of operating, and there are new cuts illustrating the latter's plan of subperitoneal muscular resection and introduction of sutures for closing the uterine wound. Dr. Harris's latest statistics are also given. Porro's operation and its modification by Müller are carefully treated, and Fehling's admirable directions are clearly given.

In his treatment of the aetiology of spondylolisthesis, the author gives the results of the recent investigations of Neugebauer, which appear to prove that the deformity is not due to a separation of the articular processes of the last lumbar from those of the first sacral vertebra, as hitherto supposed, but certainly, "in many cases, to a congenital separation of the arch from the body of the fifth lumbar vertebra, due to defective ossification." The chapter on abnormalities of the fetus as a cause of dystocia, contains a new section on shortness of the cord, and another on transverse presentations. We are glad to see in the chapter on eclampsia, a description of Breus's method of treatment with hot baths, a method which has given good results in Vienna. On page 639, is a valuable new section on nerve exhaustion and shock, in which this anxious, and often fatal condition, is most graphically described. The chapters on puerperal fever have been largely rewritten, and the subject is presented in a masterly manner from the standpoint of modern investigation. The index has been considerably enlarged, and convenience in using the book thereby increased.

In concluding our necessarily brief review of this most admirable work, we are glad to call attention to the correction in this edition of a grave error in the designation of the oblique diameters of the pelvis. In his earlier editions, the author named the oblique diameters right or left, according as they are directed towards the right or left *acetabulum*, thereby confusing all who are in the habit of consulting other authorities. He now designates the diameters right or left according to the *sacro-iliac symphondrosis* towards which they are directed, and thus adopts the conventional nomenclature of Spiegelberg, Barnes, Schroeder, Playfair, Braun, and other eminent authors.

C. M. G.

—Dr. A. Walker writes to the *British Medical Journal*: "In a number of cases, strychnine administered along with iron for a month before labor, has exerted a remarkable influence in preventing post partum hemorrhage, where severe flooding has occurred in previous labors."

# Medical and Surgical Journal.

THURSDAY, DECEMBER 31, 1885.

*A Journal of Medicine, Surgery, and Allied Sciences, published weekly, by CUPPLES, UPHAM & CO., Boston. Price, 16 cents a number; \$5.00 a year, including postage, to subscribers in the United States and Canada. Foreign subscribers are charged the postage in addition.*

*All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal.*

*Subscriptions received, and single copies always for sale by the undersigned, to whom remittances by mail should be sent by money-order, draft, or registered letter.*

CUPPLES, UPHAM & COMPANY,

283 WASHINGTON STREET, BOSTON, MASS.

## ANNUS MEDICUS, MDCCLXXXV.

UPON the first day of the current year, the JOURNAL indulged in a brief retrospect of some of the vicissitudes of medical journalism during the nearly sixty years of its career as a weekly publication. Upon the closing day of the year, and in its fifty-third issue, it takes leave, in accordance with a previous custom, to lay before its readers a short review of some of the occurrences of medical interest which the year has brought forth.

The epidemiology of the year has to do chiefly with cholera and variola. The former disease, which ravaged Italy and the south of France during 1884, transferred its worst scene of operations into Spain. During the summer the disease extended widely through that country. In the later months of the year its spread was materially checked, although not till nearly 500,000 cases had occurred. The mortality was over 100,000, the per cent. of deaths apparently being somewhat less than in the preceding year in Italy, though the imperfectness of returns casts doubt upon the accuracy of any published death rates.

The epidemic scourge of this continent has been small-pox, which, during some eight months was very prevalent in Canada. A rigid system of inspection and of compulsory vaccination, under the supervision of the United States Marine Hospital Service, was maintained along the frontier, and medical officers boarded all trains coming from over the line. Baggage from suspicious localities was, in many cases, detained for disinfection. These efforts, combined with the thorough and energetic action of the health officers in cities especially exposed to importation of the disease, have secured a general exemption from the disease in the United States. In Montreal, at the height of the epidemic, the deaths daily averaged from sixty to seventy, and it was believed that some four thousand cases existed at one time in that city. Within the past six weeks the epidemic has decreased to a great extent, and at the present time has practically ceased, or shall we rather say, is in abeyance? For the spirit which led to antivaccination riots in the summer is still unchanged, and even after the ravages of the disease, there still remains fuel for it in the

numerous persons unprotected by the only reliable safeguard. Notwithstanding the zealous propitiatory cult which has been rendered by the inhabitants to all the saints of the calendar, there is still room for the question *quo numine laeso*, and the answer is *SS. Hygieia et Vaccinia*.

The report of the English Cholera Commission, sent out to India by the Home Government, was made public early in the year, and its verdict was adverse to the claim of Koch that the comma bacillus has a specific relation to the disease. They recognized the comma bacillus in the intestines of cholera patients, but claimed it to be developed as the result of post-mortem changes. Their own bacillus (must every commission find one in order to keep up its national credit?) was straighter than that of Koch, and was otherwise differentiated. Unfortunately the report, apart from the negative office of disputing the significance of Koch's spirillum, was barren of much fruit.

An International Sanitary Conference was held at Rome in the earlier part of the year, whose investigations were especially directed, as was natural, to the means of protecting Europe from the invasion of cholera. The conclusions of the conference held some years ago at Vienna, were adopted as a starting-point. Land quarantine was condemned as emphatically as was done at Vienna, but the sea quarantine, which at the former conference was established at seven days, was, on the motion of the French delegation, reduced to five days. The British and Indian delegates refused their assent to maritime quarantine, as vicious in principle, useless in practice, and dangerous as tending to divert attention from more effective sanitary measures. The line of policy advocated by the French delegates, however, prevailed, and a diminution in the rigor and inconvenience of quarantine has served only to fasten the fact of quarantine for a time longer on the nations of Europe.

In the domain of bacteriology, public attention has been chiefly engrossed by attempts to adapt the microbes to the practical end of preventive inoculation. Koch, and perhaps we may say the more conservative bacteriologists generally, have failed to receive any new light on this practical application of their studies. The existence and pathological significance of the tubercle bacillus have received confirmatory testimony and may now fairly be said to have gained general professional acceptance. And, while Koch's laboratory has been crowded with eager and zealous students, the problem of protecting the race through a possible inoculation of bacilli of mitigated virulence, seems as far from solution as ever.

During the past summer, however, Dr. Ferrán has inoculated widely in the cities of Spain, what he claims to have been a culture-fluid, containing the microbes of cholera. The only demonstrable results have been a moderate local inflammation, sometimes amounting to abscess on the arms of the patients, and a large influx of gold to the pockets of the operator. A committee of the French Academy, appointed perhaps on the strength of Ferrán's professed devotion to Pasteur,

and laudation of the latter's discoveries, visited Spain, but were given no information as to the character or mode of preparation of the mysterious fluid inoculated, and saw no evidence that the process gave any immunity against the scourge, a conclusion which was merely confirmatory of the *à priori* objection that, as having the disease once was no protection against a second attack, so, also, inoculation with the bacilli of cholera could confer no immunity.

Meantime, however, the illustrious chemist whom Ferrán professed as his master, has been demonstrating what he claims to be a preventive inoculation of a more dreaded disease—hydrophobia. The announcement of successful inoculation for this purpose was made to the International Congress of 1884, but experimental proofs were for some time not forthcoming, and there are still skeptics who are not satisfied that the disease produced in the inoculated rabbits and dogs was hydrophobia at all. Finally, in the fall, Pasteur communicated to the Academy two cases, in which hydrophobia was to have been expected, and in one of which, after repeated inoculations, it has not appeared in one hundred days. The uncertain and always long incubative period of this disease, makes necessary a prolonged period of time for the completion of such observations. In the interval, however, many persons, bitten by rabid dogs, have subjected themselves to Pasteur's inoculations. Just at the present time this is the popular craze, and numerous persons on this side the water, who have been bitten, seem at once to have become rabid on the subject of Pasteur. What may possibly be made by fate a "control experiment," is now going on with six children from Newark, N. J., who were bitten by a dog, alleged, on somewhat less loose evidence than usual, to be mad. In four cases the parents concluded to try inoculation, and in the other two they refused. The four children, sent abroad through the generosity of Mr. Carnegie, of Pittsburgh, have arrived, and been operated upon, the details being given with considerable fulness in the daily press, and even calling forth the imaginative powers of the "special artist." If the four escape, while the two die, Pasteurization will have a further boom; if all escape, or if the two escape and the four die, it will be time enough to decide what we shall then think.

Nothing that the year has brought forth is more productive of shame and disgust to the American medical profession than the developments in regard to the proposed International Congress of 1887. The beginning of the year found the original Committee of Arrangements, which had been appointed by the American Medical Association in 1884, successful in the acceptance of their invitation presented to the Copenhagen Congress to meet in Washington in 1887, and well advanced in the arrangements which they considered themselves empowered to make for the organization of the Congress. At the meeting of the American Medical Association in New Orleans, in April, after an unseemly wrangle, led by men whose

opposition, founded, it is to be feared, on ungratified personal ambitions, was cloaked in solicitude for the "code," and a desire to see the honors of the occasion awarded on a geographical basis, the work of this original committee of seven was disallowed, and the committee, increased by the addition of one man from each state and territory, and each of the government services, was authorized to make all the arrangements for the Congress. This enlarged committee, of about forty-five members, has held two meetings, the first at Chicago, June 24th, at which the American membership in the Congress was restricted to medical societies in affiliation with the American Medical Association; the number of sections was reduced from nineteen (as provided by the original committee), to sixteen, many of the original appointees dropped, and the officers selected on the basis of territorial representation.

Resignations began promptly to pour in from the leading men of the leading medical centres, so that to fill the decimated ranks, another meeting of the Committee of Arrangements became necessary. This was held in New York, September 3d. But still the stream of resignations has continued. At the second meeting, the constituency of the Congress was extended so as to include all members of the regular profession of medicine. Some of the removals that had been made at the previous meeting were reconsidered, a list of rules for the government of the Congress was adopted, and an executive committee appointed, which sub-committee proceeded at once, in contravention of the very principles which had been insisted on at New Orleans, to make itself autocratic by declaring itself irresponsible for its acts, either to the Committee of Arrangements or to the American Medical Association.

Very recently a meeting of men interested in a compromise of existing difficulties, has been held in Philadelphia, and a proposition has been made that this last executive committee, augmented by a number of gentlemen whom they have chosen of their number, but who have hitherto declined to serve in that capacity, unite with the original (enlarged) Committee of Arrangements to organize the Congress *de novo*. This plan has not as yet succeeded, and the time is rapidly slipping away during which any solution of the difficulty is possible. Meantime, the foreign members of the Congress, who accepted the invitation to Washington only on condition that all questions of the code and local medical politics should be left out of account, do not seem to be engaging their stair-rooms for an Atlantic trip in the summer of 1887. As one of the ablest of our English contemporaries remarks, "The American Medical profession is not so rich that it can afford to play all Europe with only pawns on its side of the board."

During the summer, much interest and excitement were aroused both here and in England, through the publication in the *Pall Mall Gazette* of what purported to be an exposure, in the interest of public morality, of the dangers to which girls of thirteen years and over are exposed through the legalizing of that as the age

of "consent," whereby men who seduce them can be held free of the charge of rape. Of the wisdom of this publication, which was made under the title of "The Maiden Tribute of Modern Babylon," in a special issue of the journal, with sufficient warning so that regular subscribers might keep it out of the hands of their families if they so desired, there was naturally great difference of opinion. The ostensible purpose of the publication, namely, the raising of the legal age of "consent" to sixteen years, was accomplished. But more recently, Mr. Stead, the proprietor of the paper, has been tried, with some of his coadjutors in this business for illegal methods, in compassing the abduction of a girl, Eliza Armstrong, which abduction was undertaken for the purpose of demonstrating what an enormity could be accomplished under protection of existing laws. The conviction seems to show that the facility for the sale of virgins, afforded by existing laws, was not so great as was claimed. A most unfortunate development of the affair was the implication of a member of the medical profession, Dr. Heywood Smith, in the unprofessional act of having chloroformed the girl, against her knowledge, for the sole purpose of examining her with a view to the whitewashing of a man who had wilfully laid himself open to the suspicion of having violated her. This act met with a most scathing but deserved rebuke from the judge, and is expected to call forth discipline from the censors of the College of Physicians, to which body Dr. Smith belongs. Meantime, much of the good which might otherwise have arisen from this whole unsavory business, is outweighed by the odium attaching to the mistaken policy of doing evil that good may come.

The sympathies of the medical profession, as indeed those of the whole civilized world, have been drawn out during the year towards General Grant through his patient endurance of the painful and lingering disease, which terminated with his death in the latter part of July. Early in the year, the cancerous disease had made inroads which precluded the possibility of surgical interference. In the spring months, although the extent of the diseased process was not great, the constitutional depression was alarming, and from the wearisome prolixity of the published bulletins, as well as from the small amount which they left to the imagination, the public anticipated his death almost hourly. The separation of a small slough, however, was accompanied by such an improvement in the constitutional symptoms, that the sufferer was able to complete the literary task upon which he was engaged, and to be removed from New York to Mt. McGregor, where he heroically awaited the inevitable.

A bill to regulate the practice of medicine, which was introduced into the Legislature of Massachusetts last winter, was defeated by an overwhelming vote, the wailing cry of "medical monopoly" being raised, and the advocates of "free medicine" organizing with a definiteness of purpose which had nothing to compare with it upon the other side. The same Legislature, however, passed a Pharmacy Bill, which provides for a Board of Registration, to consist of five druggists, one to be appointed by the Governor each year, and all for a

term of five years, to meet, at least, three times a year, and to examine all persons desirous of engaging in the business of pharmacy. Such a Board has been organized, and has served notice upon all druggists doing a retail dispensing business in the State, to apply for registration. Candidates for examination may appear before the Board on the first Tuesday of January, May, or October, and all pharmacists who have been engaged in business three years prior to January 1, 1886, are entitled to registration without examination on the payment of fifty cents.

Among the important stated lectures of the year in England, were the Lettisonian on "Disorders of Digestion, Their Consequence and Treatment," by T. Lauder Brunton, M.D.; the Gulstonian Lectures on "Malignant Endocarditis," by William Osler, M.D., of Philadelphia; the Croonian Lectures on the "Hygienic and Climatic Treatment of Chronic Pulmonary Phthisis," by Hermann Weber, M.D.; the Lumsden Lectures on "Some Points in the Natural History of Primitive Dry Pleurisies," by Sir Andrew Clark, Bart., M.D.; the Cavendish Lecture on "Hysteria and its Counterfeit Presentments," by J. S. Bristowe, M.D., LL.D., F.R.S.; the Bradshaw Lecture on "Morbid Arterial Tension," by James F. Goodhart, M.D., F.R.C.P.; the Bowman Lecture on "Ophthalmology and Diseases of the Nervous System," by J. Hughlings Jackson, M.D., F.R.S.; the Biennial Hunterian Oration, by John Marshall, F.R.S.; the Annual Harveian Oration, by Richard Quain, M.D., F.R.S.

Some of the more important annual society meetings for the year have been the following: The American Surgical Association held its thirty-sixth annual meeting at New Orleans, April 28 to May 1. The American Medical Association held its thirty-sixth annual meeting at New Orleans, April 28 to May 1. The Association of American Medical Editors met at New Orleans, April 27. The American Climatological Society met in New York, May 27-28. The American Neurological Association held its eleventh annual meeting in New York, June 17-19. The American Laryngological Association held its seventh annual meeting in Detroit, Mich., June 24-26. The American Otological Society held its eighteenth annual session at New London, Conn., July 14. The American Ophthalmological Society met at the same place on the two following days, July 15 and 16. It was the twenty-first annual session. The British Medical Association held its forty-third annual session at Cardiff, Wales, July 28-31. The American Dermatological Association held its ninth annual meeting at Greenwich, Conn., August 26-28. The American Association for the Advancement of Science met for the thirty-fourth year, August 26 to September 1, the place of meeting being Ann Harbor, Mich. The American Gynecological Society held its tenth annual meeting at Washington, September 22-24. The American Academy of Medicine held its ninth annual meeting at New York, October 28-29. The American Public Health Association held its thirteenth annual session at Washington, December 8-11.

Among the State medical societies, the Massachusetts held its one hundred and fourth meeting at Boston, June 10; the Ohio its fortieth meeting at Dayton, June 3-5; the Rhode Island its seventy-fourth, at Providence, June 11; the Maine its thirty-third, at Portland, June 9-11; the New Hampshire its ninety-fifth, at Concord, June 16; the Pennsylvania its thirty-sixth, at Scranton, May 27-29; the New York State Medical Association its second, at New York, November 17-19; the Medical Society of the State of New York, its seventy-ninth, at Albany, February 3-5.

## GENERAL NECROLOGY.

William Braithwaite, M.D., of Leeds, Eng., died January 31, at the age of seventy-eight. He filled honorable posts in hospitals and a medical school of Leeds, but is best known to American readers as founder of *Braithwaite's Retrospect*, which he began in 1840.

Costano Mazzoni died at Rome, February 5, at the age of sixty-two. He was one of the most prominent Italian surgeons, was a friend of such men as Lister and Billroth, and was Professor of Clinical Surgery in the Roman University. His numerous contributions to the *Accademia Medica di Roma* were among the most valuable scientific papers in Italian literature.

Professor Louis Elsberg, M.D., a pioneer in the specialty of laryngology, and first President of the American Laryngological Association, for seventeen years a member of the faculty of the University Medical College, and later, Professor of Laryngology at Dartmouth and in the New York Polyclinic, died in February of Bright's disease, at the age of forty-seven.

Professor Etherslie Wallace, M.D., at first Demonstrator of Anatomy, and later, and up to two years ago, Professor of Obstetrics in the Jefferson Medical College of Philadelphia, died March 9, at the age of sixty-six. He was for a short time Dean of the College, succeeding Professor Gross.

Ebenezer Pye Smith, F.R.C.S., intimately connected with the earlier traditions of Guy's Hospital and Medical School, though ten years retired from practice, died March 9, aged seventy-eight.

Prof. P. A. Pamm, who occupied the chair of Physiology at Copenhagen, and who became known to many Americans, as the president of the last International Medical Congress, died during the spring. He had made valuable contributions to scientific pathology among his more noted works being one upon embolism.

Professor von Frerichs, of Berlin, died March 14, at the age of sixty-six. His scientific studies were carried on at Göttingen, where he began teaching as privat-docent. At first, he devoted himself to chemistry and physiology more than to medicine, but he soon found his account in clinical medicine, which he began to teach at Breslau in 1851, in connection with pathology. Called to Berlin in 1859, he gained a world-wide reputation as a clinician. He presided at the recent meetings of the German Medical Congress, and he had recently been highly honored on the occasion

of the completion of the fiftieth year of his University labors.

James Lawrence Little, M.D., Professor of Surgery in the New York Post-graduate Medical School, died April 4th, of peritonitis, following a perforation of the vermiform appendix. He was born in 1836. He had held a number of important hospital services, and had a wide reputation as an operator. Among valuable monographs of his, may be mentioned one on the median operation of lithotomy, which operation he was believed to have performed more frequently than any other American surgeon.

Frederic Gustave Jacob Heide, professor of anatomy and director of the Anatomical Institute at Göttingen, died May 18, at the age of seventy-six. His earliest work as an instructor in anatomy was done at Berlin, where as prospector to the medical faculty of the University, and afterwards as privat-docent, he broke ground in the then untilled field of microscopical anatomy. In 1840, he was made professor of anatomy, and later of physiology in the University of Zürich. Four years later he was called to a professorship at Heidelberg, and during the eight years that he remained there, produced the great work of his life, the "*Handbuch der Rationellen Pathologie*." The "*Handbuch der Systematischen Anatomie des Menschen*" was published, the first volume in 1855, the second in 1864, and the last in 1868.

Carlo Maggiorani, physician, littérateur and statesman, prominent in the Roman Academy of Medicine, and one of the earliest and ablest promoters of the *Gazette Medica di Roma*, died in Rome, August 12, aged eighty-five.

Dr. Paul Börner, of Berlin, a life-long political reformer, and equally enthusiastic in hygiene and sanitary reforms, the founder of the *Medicinishe Wochenschrift* as well as of the *Reichs Medicinal-Kalender* and probably the leader of German medical journalism, died suddenly August 29, at the comparatively early age of fifty-seven.

William Augustus Guy, M.D., F.R.S., professor of forensic medicine in King's College, London, from 1838 to 1870, and dean of the medical department for twenty-two years, professor of hygiene in 1869, at one time president of the statistical society, vice-president of the Royal society, and the holder of a number of the most important annual lectureships, died September 10, aged seventy-five.

Prof. Samuel G. Armor, M.D., dean of the faculty of Long Island Hospital Medical College, and formerly an assistant of the chair of therapeutics, materia medica and general pathology, and later of that of the practice of medicine and clinical medicine, in which he succeeded Dr. Austin Flint, died October 27. He had, prior to his removal to Brooklyn in 1866, held professorships in several western medical colleges.

William B. Carpenter, M.D., F.R.S., born October 29, 1813, met his death November 9, by a painful accident which is still fresh in the minds of our readers. His monumental work on human physiology,

which reached eight editions, and in his recently established journal, the *Asclepiad*, to which he contributed so abundantly, his indefatigable labors, not only in strictly professional grounds, but also in other branches of science, as zoology, geology, hypnotism, and finally in connection with deep-sea dredging, and his lectures before the Lowell Institute of Boston, on Human Automatism, do not require rehearsal. He was a many-sided and most industrious man.

Professor Giuseppe Ponzi of the chair of anatomy and physiology in the University of Rome, equally eminent as a student of the science of geology, the author of a hundred monographs on various scientific subjects, died the last of November, aged eighty years.

John W. Sawyer, M.D., Superintendent of the Butler Hospital for the Insane, at Providence, R. I., and an experienced alienist, died December 14, at the age of fifty.

Albert Holmes Smith, M.D., a prominent obstetrician and gynaecologist of Philadelphia, died after a lingering and painful illness on December 14, at the age of fifty. He was appointed one of the obstetricians to the Philadelphia Hospital in 1862. He was one of the founders of the Philadelphia Obstetrical Society and its president from 1874 to 1876. He was also prominent in the formation of the American Gynaecological Society, and was its president at the ninth annual meeting, held last year. Of his numerous contributions to medical literature, some of the most valuable are contained in the published Transactions of this society. Of his inventions in the line of gynaecological instruments, we may mention hard rubber urethral dilators, a uterine speculum, and what is best known in connection with his name, a modification of the Hodge pessary, which is perhaps more widely used than any instrument for a similar purpose in this country. Dr. Smith lectured for many years in a school which was founded by his old preceptor, Dr. Joseph Warrington, in connection with the Lying-in Charity.

John C. Draper, M.D., LL.D., died in New York, December 20. He was born in Virginia, March 31, 1835, and was the oldest son of the late Professor John H. Draper. In December, 1858, he was made professor of analytical chemistry in the University of the City of New York, which position he held for thirteen years. From 1860 to 1863 he was professor of chemistry in the Cooper Institute. In 1863 he also occupied for the first time the chair of natural history in the University of the City of New York, which he has since held. In 1866, he became professor of chemistry in the medical department of the university. He was the senior member of the faculty of the Medical College, and also was treasurer. For a number of years he contributed a series of semi-scientific articles to the *Galaxy* and *Scribner's Monthly*. He published in 1875, a textbook on anatomy, physics and hygiene. He edited *Scribner's Year Book of Nature and Science* for 1872, and *Draper's Year Book of Nature and Science* the year following and up to 1876. Besides a

large number of scientific papers of considerable importance published subsequent to this, Professor Draper published in 1882, a "Practical Laboratory Course in Chemistry." His last work was an advanced textbook of medical physics.

In addition to the names already mentioned, Germany has lost during the year: Professor Fehling, of Stuttgart, the inventor of Fehling's test for sugar, who died July 1, at the age of seventy-two. Professor Ludwig Schlager, Director of the Wiener Landes-Irrenanstalt, and one of the most eminent alienists of Austria, who died August 4, aged fifty-seven. Professor Berger, of Breslau, a well-known neurologist. Professor Charles Seby, recently called to the chair of anatomy at Prague.

France also has been called upon during the year to part with several of her men most eminent in science and medicine: Rabuteau and Yvaren, of considerable home reputation as practitioners and writers; Ernest Dubreuil, of Montpellier, the founder and publisher of the *Revue des Sciences Naturelles*; Henri Milne-Edwards, chiefly known as a zoologist, the successor of Cuvier in the Academy of Sciences and of Geoffrey St. Hilaire as Professor at the Jardin des Plantes, who died July 29, at the ripe age of eighty-five. Gueneau de Mussy, accomplished as a scholar and great in therapeutics, whose medical writings are models of their kind; Charles Robin, distinguished as a histologist and lexicographer; Bailliere, the Nestor of medical publishers, and lastly Henri Bouley, whose death happened on the first inst., who has perhaps done more than any other man of the age to advance veterinary medicine to a level with the progress made in human medicine, while at the same time bringing from the former a powerful illumination to bear upon the latter, and for which medical science cannot be too grateful. He was the successor of Claude Bernard at the Museum and inaugurator of the chair of Comparative Pathology, editor of the "Recueil de Médecine Vétérinaire," and lastly president of the Academy of Sciences. He early embraced the doctrines of Louis Pasteur, of which he was the most ardent defender; recognizing the immense future in store for microbiology, which in his estimation, was destined to disclose the secrets of every form of contagious disease. Of the works which M. Bouley has left behind him, the best known and most important are his "Leçons de Pathologie Comparée," "Le Progrès en Médecine par Experimentation," published in 1882, and his "Nature Vivante de Contagion," published last year.

#### NECROLOGY OF THE MASSACHUSETTS MEDICAL SOCIETY.

One of the most eminent and lamented practitioners died at the close of last year, too late to be included in the necrology of that year.

William Henry Thorndike, M.D., died in Boston, December 26, 1884, aged sixty years, six months.

Andrew Marion William White, M.D., died in Fall River, January 5, 1885, aged forty-two years.

Levi Howard, M.D., died in Chelmsford, January 23, aged sixty-five.

Ebenezer Turell Learned, M.D., died in Fall River, February 12, aged seventy-two.

John Pierce, M.D., died in Edgartown, March 27, aged seventy-nine.

William Osgood, M.D., died in Boston, April 10, aged sixty-two.

Robert William Hooper, died in Cambridge, April 13, aged seventy-four.

Samuel Cabot, M.D., died in Boston, April 13, aged sixty-nine.

William Hathorn Gage, M.D., died in Taunton, April 21, aged fifty-four.

Andrew Alexander, M.D., died in Dorchester, April 22, aged seventy-three.

Joseph Cummings Batchelder, M.D., died in Templeton, April 26, aged seventy-six.

Joshua Brackett Treadwell, M.D., died in Boston, May 6, aged forty-four.

Alfred Clark Downing, M.D., formerly of Palmer, died in Roxbury, May 11, aged thirty-six.

Jonathan Walter Dandolo Osgood, M.D., died in Greenfield, May 16, aged eighty-three.

Joseph Ferdinand Gould, M.D., died in South Boston, June 5, aged fifty-five years, six months.

Henry Robert Vaille, M.D., died in Springfield, July 15, aged seventy-six.

Joseph Rutter Draper, M.D., died in South Boston, August 5, aged fifty-five.

George Anson Bates, M.D., died in Worcester, August 9.

James Joseph Sullivan, M.D., died in Lowell, August 11, aged twenty-eight.

William Henry Aiken, M.D., died in Malden, September 16, aged thirty-six.

James Wolcott Foster, M.D., died in North Attleborough, September 17, aged seventy-two.

William Workman, M.D., died in Worcester, October 17, aged eighty-seven.

George Otis Warner, M.D., died in Leicester, November 12.

Frederick Howard Lombard, M.D., died in Boston, December 15, aged thirty-three.

John Orne Green, M.D., died in Lowell, December 23, aged eighty-six.

John Leland Sherman Thompson, M.D., died in Lancaster, December 25, aged seventy-four.

#### MEDICAL NOTES.

— A means of treatment for insomnia, which has been found useful by Dr. Von Gellhorn (*British Medical Journal*, November 7), is bandaging the legs with a bandage, of which a portion is wrung out in cold water, the dry part being applied over the wet. A dilatation of the cutaneous vessels is produced, which diminishes the cerebral circulation and induces sleep.

— Austrian newspapers report that six of the American medical students at Vienna not only offered

to Serbia their gratuitous aid in attending the wounded, but actually left for the front, and six others held themselves ready to start.

— A Paris despatch announces that the four Newark children who have been inoculated by M. Pasteur, will sail for home January 3. They are all well.

#### NEW YORK.

— The new Croton aqueduct is a very costly affair in lives, as well as in money, and since the work began, thirty-five men have been killed by accidents at the various shafts. On the 7th of December, five men lost their lives at shaft No. 3, in the town of Neweastle, about four miles back of Sing Sing, on the Hudson, and two days later, there was another fatal accident at shaft No. 4, which made nine deaths altogether within a fortnight.

— The thirteenth annual meeting of the State Charities Aid Association was held December 17th. Its object is to look after the manner in which the officials of public charities perform their duties, having been granted visitatorial powers in the various public and charitable institutions in 1881, and, when necessary, to arouse public opinion and make it effective in the correction of abuses in the administration of such institutions. It has committees and visitors in fifty counties throughout the State, and has been the means of accomplishing a considerable amount of good.

— A meeting called for the organization of a section of Laryngology of the New York Academy of Medicine, was held in the rooms of the Academy, on the evening of December 23d, 1885, the President of the Academy occupying the chair. A valuable paper, entitled "The surgical uses of electricity in the upper air passages" was read by Dr. R. P. Lincoln, and was followed by an interesting discussion. Dr. Rufus P. Lincoln was elected President, and Dr. D. Bryson Delavan, Secretary of the section for the ensuing year, and a general plan of organization adopted. The interest in the section manifested by the members present, gave gratifying assurance as to its future success.

#### Miscellany.

##### INSTANTANEOUS DEATH BY LIGHTNING WITHOUT VISIBLE LESION.

A case was recently reported by Dr. Forman to the Philadelphia County Medical Society, of a mulatto woman who was killed by lightning in August last, under the following circumstances:

The deceased was a robust woman who had always enjoyed excellent health. On the day of the accident she, with her husband, nephew, and son, were seated in the order mentioned, on a wooden bench, which was placed under a tree. The individual killed was seated on the end approximating to the trunk of the tree. The storm was approaching, and as the rain had not commenced to fall, they remained watching the unusually heavy clouds. Suddenly the flash occurred,

instantly killing the woman, rendering temporarily unconscious the nephew, and occasioning a transient anesthesia of the feet of the husband. The nephew remained totally unconscious for about twenty minutes, and partially conscious for five or six hours, by which time he was thoroughly himself. The only pain experienced was a deeply-seated epigastric one, which persisted for forty-eight hours, and headache, of one day's duration. The anesthesia, which was limited to the lower extremities, was pronounced for two days, when it began to ameliorate, and in the course of a week had entirely disappeared. The sphincters escaped and there were no local paralysis. In this case careful examination failed to discover any traces of lightning burn. The husband simply suffered slight numbness of the feet, which lasted for an hour or two and disappeared. Interrogation revealed the fact that the nephew did not experience any pain at the reception of the shock, and the only thing he remembers is his recovery of senses, just as if waking from a deep sleep, with a loss of power and sensation of extremities, for the cause of which, until the commotion was explained, he possessed no satisfactory solution. The husband experienced a sense of pain accompanying the shock.

Dr. Beates, in his remarks upon the effects of lightning upon the human body, called attention first to the total absence of rigor mortis and of coagulation in the present case, effects which have been denied by high authorities, notably by Dr. B. W. Richardson, who experimented upon animals with the Leyden jar, and concluded that rigor mortis and coagulation constituted, in an especial degree, the direct effects of fatal shocks of electricity.

Dr. Beates recognizes two classes of cases of sudden death, the first with, the second without, external evidences. In the former there are burns, manifesting themselves in different degrees in the same subject; and it is a matter of remark that almost all of those in whom there is wanting external evidence, present the phenomena of absence of rigor mortis and such organic alterations of the blood as result in destruction of its power to coagulate, while when burns, bruises, etc., are present there also is rigor mortis and coagulation. This conclusively demonstrates that the lightning bolt effects its fatal consequences in a diverse manner: on the one hand the force effecting a fatal result by direct action upon the centre of the organism, probably, as in the instance reported above, by injuring the cerebro-spinal centres; on the other, by a diffuse process, in which both the exterior and interior parts are involved.

#### THE PHYSICIAN'S DUTY AS TO PATENTED ARTICLES.

A recent number of the *American Druggist* contains an interesting editorial upon this ethical question. After taking the ground that all those, whether physicians or pharmacists, "whose profession has a direct bearing upon the relief of suffering humanity should be considered as having renounced the moral right to secure or control patents, on any articles that are primarily used for remedial purposes;" and admitting that a relatively smaller number of pharmacists feel their obligation in this regard than of physicians, the article goes on to consider the important point of the proper relation of those who may use patented articles

to those who *own* the patents. The writer remarks: It is the prerogative of the physician to employ for the cure of disease any method of treatment which he conscientiously believes to be conducive to the benefit of his patient. But it is not only his prerogative, it is even his *duty* to do so, if he knows that favorable results may be expected from the use of some remedy or appliance, even though they be claimed by a particular sect as quasi-proprietary, or else be guarded by a patent. If the physician has the choice between a non-patented and a patented article, he will quite naturally prefer the former, provided it is equally serviceable. But if the latter answers the purpose better, he is perfectly justified in recommending and employing it. The onus of immorality attaching to such a patent belongs to the patentee exclusively, but *not* to the person who uses it or is compelled to use it in want of something equally good and unpatented.

In following this argument, it should always be remembered that a patent implies not merely a monopoly, but at the same time removes all secrecy from the invention. Every one, therefore, who uses a patented article or invention has full opportunity of examining its details and its adaptability to any special case. The reverse is the case with so-called proprietary medicines, the composition of which is kept secret, and which are copyrighted by title. It is hard to understand how any physician can persuade his conscience that he is justified in using such preparations—the composition of which is at the discretion and mercy of men seeking to make money—in the treatment of the sick.

From the above, it follows that a physician is perfectly justified in employing an article patented by others, provided he considers it of special benefit to his patient. On the other hand, he is not justified in using proprietary "medicines," of unknown composition, the ingredients of which may at any time be altered by the maker without his knowledge. Incidentally, also, it follows that the whole business of manufacturing, selling, or using proprietary "medicines" is unjustifiable, wrong in principle, and indefensible as long as there is any secrecy maintained about their composition.

It is probably known to all who read this that *no product of nature*, whether existing as such ready formed in any of the three natural kingdoms, or artificially obtainable as a definite compound of constant composition and characteristic properties (such as many artificially prepared organic chemicals), is capable of being patented. Only the special *processes* by which such products are reached can be protected by a patent. If another inventor discovers an entirely different process leading to the same result, he is as much entitled to a patent as his predecessor. There are numerous indispensable articles used in medicine which have been at times, and are even now, partly hedged around by patents, but in almost all of these cases the patent does not amount to a monopoly, inasmuch as there are channels left open by which the same article may be procured without an embargo. Take the case of salicylic acid. This may be obtained perfectly pure from oil of wintergreen, and is in fact manufactured from this source for the market. There is no patent on this. But the process discovered by Prof. Kolbe, which enabled the acid to be made at a low price on a very large scale, is protected by a patent. The patented acid is much cheaper and equally pure as the natural. Would any one plead in favor of using the more expensive natural acid, merely because the artificial is pa-

tented? Many other such cases might be cited, but the argument in favor of the patented article would remain the same.

In like manner it is shown that the new antipyretic, antipyrine, is made under a process that is patented. Its chemical composition and mode of preparation have been announced to the public through the patent publications. It therefore is proper for the physician to make use of the unequalled antipyretic powers of the drug. Meantime, should another investigator hit upon a different method of preparation, the latter could have the choice either of throwing open the right of manufacture to the world at large, or of protecting his new process, likewise, with a patent.

And tradition says that the virus first used in 1856 was of the Jennerian stock, introduced into this country by Dr. Waterhouse. Dr. Snow who was, for twenty-eight years, Superintendent of Health, and who had ample opportunities for testing its protective power, found that its efficiency in this respect, was in no way impaired. Nearly 47,000 persons have been vaccinated with this virus, and our experience has been that while it is certainly not inferior to the bovine virus in protective power, it is decidedly superior to it, in that it is much less liable to make a troublesome sore, and is much more certain to "take" than any animal virus which we have ever been able to obtain. When my annual report is printed, I will send you a copy giving a detailed account of our methods.

Yours truly, CHARLES V. CHAPIN, M.D.

## Correspondence.

### HUMANIZED VIRUS.

HEALTH DEPARTMENT. OFFICE SUPERINTENDENT OF HEALTH.

PROVIDENCE, R. I., Dec. 26, 1885.

MR. EDITOR:—

I noticed in your issue of December 10th, that Dr. S. C. Martin is reported as saying that "it is no longer possible to observe the effects of long humanized virus." I desire to call your attention to the fact that humanized virus has been used continuously by this department since 1856. The stock has been maintained by continuous transmission from child to child, without being once renewed from the cow.

### SCIENCE? LOGIC?—OR WHAT?

MR. EDITOR:—

From "so good a book," as he calls it, a reviewer in your last issue quotes with other similarly lucid and logical sentences the following:

"Beware especially of scepticism. . . . It is repugnant to reason and to conscience, that he can be a good physician who judges of no utility, all remedial agents that have the sanction of tradition and custom."

"For you must remember that pharmaceutical measures go but a little way in the cure of your patient, and that you can often accomplish more by hygiene, than you can accomplish by medicine."

What is scepticism, if this is not?

BELIEVER.

Deaths reported 1,388; under five years of age 483; principal infectious diseases (small-pox, measles, diphtheria, and croup, whooping-cough, erysipelas, fevers, and diarrhoeal diseases) 210, consumption 277, lung diseases 203, diphtheria and croup 99, typhoid fever 16, diarrhoeal diseases 21, whooping-cough 20, erysipelas three, purpural fever two, small-pox one. From whooping-cough, New York 19, Baltimore one. From typhoid fever, New York five, Cincinnati four, Boston and New Bedford two each, Charleston, Worcester and Taunton one each. From malarial fever, New Orleans five, New York four, Baltimore, and Cincinnati one each. From cerebro-spinal meningitis, Worcester three, New York two, Cincinnati, Charleston, Fall River and New Bedford, one each. From erysipelas, New York one. From purpural fever, Boston and Cambridge, one each. One case of small-pox reported in Boston.

In 108 cities and towns of Massachusetts, with a population of 1,285,540 (population of the State 1,941,405), the total death-rate for the week was 15.29 against 16.26 and 14.33 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,906,446, for the week ending December 5th the death-rate was 20.22. Deaths reported 3,442; infants under one year of age 813; acute diseases of the respiratory organs (London) 410, measles 123, whooping-cough 111, scarlet fever 40, fever 49, diarrhoea 32, diphtheria 26, small-pox (Liverpool three, London one), four.

The death-rates ranged from 31.3 in Bolton to 11.2 in Birkenhead; Birmingham 16.7; Blackburn 24.1; Bradford 19.5; Hull 17.4; Leeds 19.5; Leicester 19.3; Liverpool 26.7; London 19.4; Manchester 23.5; Nottingham 26.7; Sheffield 15.2. In Edinburgh 23.5; Glasgow 26.3; Dublin 24.7.

For the week ending December 5th in the Swiss towns, there were 27 deaths from consumption, lung diseases 20, diarrhoeal diseases eight, small-pox two, measles two, whooping-cough three, diphtheria and croup two.

The death-rates were: at Geneva 6.5; Zurich 9.7; Basle 24.2; Berne 19.5.

The meteorological record for week ending December 19th, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole of the United States Signal Corps:—

Week ending	Barometer.	Thermometer.	Relative Humidity.	Direction of Wind.			Velocity of Wind.			State of Weather.			Rainfall.
				7.00 A. M.	3.00 P. M.	11.00 P. M.	7.00 A. M.	3.00 P. M.	11.00 P. M.	7.00 A. M.	3.00 P. M.	11.00 P. M.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM DECEMBER 18, 1885, TO DECEMBER 24, 1885.

FRYER, B. E., major and surgeon. Sick leave extended six months on surgeon's certificate of disability. S. O. 232. A. G. O., December 21, 1885.

VICKERY, R. S., major and surgeon. Relieved from duty in Department of the Columbia, to repair to Washington, D. C., and report in person to surgeon-general for duty in connection with Army and Navy Hospital, Hot Springs, Arkansas. S. O. 233. A. G. O., December 22, 1885.

REED, W., captain and assistant surgeon. Leave extended one month. S. O. 233. A. G. O., December 22, 1885.

#### SOCIETY NOTICES.

BOSTON SOCIETY FOR MEDICAL OBSERVATION. A regular meeting of the Society will be held at the Medical Library, 19 Boylston Street, on Monday, January 1, 1886, at 8 P. M. Readers: Dr. S. H. Durgin, "On the care of contagious diseases." Dr. H. W. Cushing, "On Dislocations of the head of the Radius in children." H. L. B. RICE, M.D., Secretary.

NEW YORK STATE MEDICAL ASSOCIATION. Fifth District Branch. The third special meeting of the Fifth District Branch will be held in Yonkers, on Tuesday, March 23d, 1886. E. H. STURM, M.D., Secretary.

SOUTHERN DISTRICT MEDICAL SOCIETY. SURGICAL SECTION. The regular meeting of the Section will be held at 19 Boylston Street, on Wednesday evening, January 6th, at 8 o'clock. Communications. Dr. E. H. Bradford, "New Means of Treatment of Cat-Foot." Dr. G. W. Gay will exhibit a case of Ectropion of the Bladder, showing the results of an operation. Dr. E. T. Williams will show a new dressing for Fracture of the Clavicle. Dr. John Bonbons will show an Ether Inhaler.

S. J. MINNEY, M.D., Secretary.

#### BOOKS AND PAMPHLETS RECEIVED.

A Treatise on the Diseases of Infancy and Childhood. By J. L. Smith, M.D., Clinical Professor of the Diseases of Children in Bellevue Hospital Medical College, New York. Sixth edition, thoroughly revised with forty illustrations. Philadelphia: Lea Brothers & Co., 1885.

A Manual of Distributive Co-operation. Prepared in accordance with the provisions of Chapter 51 of the Resolves of 1885, by Carroll D. Wright, Chief of the Bureau of Statistics of Labor, Boston: State Printers, 1885.

Physician's Account Books, consisting of Ledger and Office Journal, or Ledger and twelve monthly pocket Day-book. By W. L. Hitchcock. New York.

The Origin, Work and Present Position of the National Board of Health. By Stephen Smith, M.D. New York. From the Sanitarian for December, 1885.

Transactions of the American Surgical Association. Volume III. Edited by J. Ewing Mears, M.D., Recorder of the Association. Philadelphia: Published for the association by P. Blakiston, Son & Co., 1885.

Medical Legislation. The Annual Address delivered before the Association of American Medical Editors. By Henry O. Murry, A.M., M.D. Boston, U. S. A. Reprint from Journal of American Medical Association, May 2, 1885.

Sixteenth Annual Report of the Manhattan Eye and Ear Hospital, with Throat and Nervous Departments. No. 103 Park Avenue, New York. September 30, 1884, to October 1, 1885.

The Extra Pharmacopœia with the additions introduced into the British Pharmacopœia, 1885. By William Martin-Dale, F.R.S. Medical references and a Therapeutic Index of Diseases and Symptoms. By W. Wyman Westcott, M.B., London. Fourth edition. London: H. K. Lewis, 1885.

Transactions of the American Ophthalmological Society. Twenty-first Annual Meeting. New London, Conn., 1885. Boston: Published by the Society.

Transactions of the American Dermatological Association at the Ninth Annual Meeting. Greenwich, Conn. August 26-28, 1885. New York.

Manuel de technique des Autopsies par Bonneville et P. Brien. Avec 16 figures et 5 planches. Paris: Librairie du Progrès Medical, 1885.

The Influence of Sex in Disease. By W. Roger Williams, F.R.C.S., etc. London: J. A. Churchill, 1885.

Die Alte und die Neue Medizin von Prof. Dr. Mariano Semmola, etc., Lehrstuhl von Prof. Dr. Vincenz Meyer nach der von verlassener vollständig umgearbeiteten und bedeutend vermehrten dritten Auflage: Napoli Francesco Giannini and Figli, 1885.

Report of the Committee on Disinfectants of the American Public Health Association, 1885. Baltimore: Printed for the Committee, 1885.
